Results: 30 ECHO Autism clinics were conducted during the study period. Thirty clinical cases were presented: mean age 4.5 years old (range 1– 12); most of them were male (n=25). Twenty patients presented with medical and psychiatric comorbidities, eight of them with two or more. Reasons for presentation in the ECHO Autism clinic were: difficulties in therapeutic approach focused on management of comorbidities (n=22) and diagnosis (n=8). Median age at time of concern was 18th months (range 12-60). Forty-five participants were connected in at least 50% of ECHO Autism clinics. After ECHO Autism implementation, a statistically significant improvement in participant self-perception of skills and competences in all fields evaluated was observed.

Conclusions: ECHO Autism is the first ECHO project in Uruguay focused on a primarily pediatric condition. The results of this experience shows that ECHO Autism is feasible and effective in this population. Additionally, it has an important role to improve access to diagnosis and treatment of children with autism spectrum disorder. A community of practice was achieved through participation in the ECHO Autism clinics, and self-perception about skills and competences in diagnosis and treatment of ASD improved. ECHO Autism in Uruguay is a meaningful approach to autism care and offers improved access to best practice care.

298 **176.298** University of Wyoming Echo for Autism: Leveraging Education Systems to Provide Behavioral Services in Frontier Communities.

E. Moody[1], *C. Hardesty*[2] *and S. Root-Elledge*[2], *(1)University of Colorado, Denver, Aurora, CO, (2)Wyoming Institute for Disabilities, College of Health Sciences, University of Wyoming, Laramie, WY*

Background: Individuals with autism who live in rural/frontier communities often face numerous challenges accessing services. For example, in Wyoming, there are only a handful of trained professionals with experience in autism to serve the whole state and most individuals with autism live hundreds of miles away from a skilled provider. Given this, most families must rely on the educational system to access even basic services. Unfortunately, many educators receive little to no training on how to support such students with autism. Therefore, professional development opportunities are critical to enhance the capacity of educators to support students with autism. Project ECHOÔ was originally developed to overcome similar challenges facing physicians. University of Wyoming has adapted ECHO to enhance educators' knowledge and skills related to behavioral strategies for autism, and implemented it throughout the state over the last two school years.

Objectives: 1) To describe the adaptation of ECHO for Education: Autism, 2) to the describe the ability of this program to reach remote schools, 3) to describe the impact of this program on teacher knowledge and skills, and 4) describe additional adaptations being made to the model to further support families to work with their schools on behavioral supports.

Methods: Starting in the 2016-2017 school year, ECHO for Education: Autism was deployed in each of the 48 Wyoming school districts . In line with agreements with the state, each session was free and open to anyone. As a result, participants included teachers, paraprofessionals, allied health

professionals, administrators, principals and family members. Attendance was tracked at each session using the iECHO platform used by all ECHO replication sites. Change in educator knowledge and skill was assessed using a traditional and retrospective pre/post design (before and after the school year) and weekly evaluation questionnaires.

Results: After two years of implementation, this program has offered a total of 68 weekly sessions and served 307 unduplicated participants (1247 duplicated participants). Participants have come from all 48 school districts in the state. Weekly evaluations revealed a large impact on participants' self-reported skills, M_{pre} = 2.89 (.87), M_{post} = 3.37 (.78), t = 18.27, p <.001, d = .58, and knowledge, M_{pre} = 2.89 (.83), M_{post} = 3.57 (.73), t = 20.6, p <.001, d = .75. Traditional pre/post assessments revealed knowledge and skills significantly improved over the school year, M_{pre} = 3.06 (1.14), M_{post} = 3.79 (.82), t = 4.38, p <.001, d = .74; retrospective pre/post revealed a similar effect, M_{pre} = 2.87 (1.19), M_{post} = 3.40 (1.03), t = 4.49, p <.001, d = .48.

Conclusions: ECHO for Education: Autism had significant reach statewide. It also seems to have improved skills and knowledge, although it remains unclear how much this has impacted student level outcomes. Based on this success, an additional network for families of children with autism was developed and is undergoing testing. This model has the potential to improve capacity of education systems in rural settings to serve students with autism. Additional research is needed to understand student academic and behavioral outcomes.

299 **176.299** Service Deserts and Service Oases: Utilizing GIS to Evaluate Service Availability for Individuals with ASD

A. Drahota[1], *B. R. Ingersoll*[2], *L. Bishop-Fitzpatrick*[3] *and R. Sadler*[4], *(1)Psychology Department, Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI, (3)University of Wisconsin - Madison, Madison, WI, (4)Division of Public Health, College of Human Medicine, Michigan State University - Flint, Flint, MI*

Background: ASD is a pervasive neurobehavioral disorder characterized by deficits in social communication and interactions, and restricted/repetitive behaviors, interests, or activities.[1,2] ASD's core symptoms and common co-occurring psychological disorders require specialized behavioral and psychological services throughout the life of individuals with ASD.[3,4] However, access to high quality specialty services can be hindered by socio-environmental determinants, such as a lack of available ASD providers within communities where individuals with ASD and their families live.[5,6]

Objectives: As a response to the paucity of literature related to the *availability* of community-based ASD services, this study utilized GIS methods to map the locations of ASD agencies across the state of Michigan. We hypothesized: 1) Population will be correlated with the availability of service such that fewer agencies will be located in less populated areas as compared with more populated areas; 2) SES will be correlated with the availability of ASD services such that areas with low SES will have fewer ASD services as compared with areas with medium and high SES; and 3) An interaction will be found between population and SES such that areas with low SES and high population densities will have fewer available ASD services as compared to areas with medium or high SES and high population densities.

Methods: We compiled a list of ASD providers within Michigan by conducting a systematic, iterative web-based search by county. We then geocoded the location of verified ASD specialty service providers using ArcGIS 10.4.1, and used network analysis to assess available ASD services in relation to population distribution, socioeconomic disadvantage, urbanacity and immobility.

Results: Individuals living in rural areas had significantly fewer ASD agencies available within 10 miles than individuals in suburban and urban areas—average distance to nearest ASD provider was 12.43 miles for rural areas versus 2.82 miles in urban and 3.36 miles in suburban areas. Spatial autocorrelation (Moran's I) indicated that the spatial distribution of ASD agencies was not random (p<0.01, Moran's Index<0.01); areas with greater socioeconomic disadvantage had fewer nearby ASD agencies available. Finally, Getis-Ord GI* clustering analysis was used to determine statistically significant spatial disparities. While most urban areas had good availability of ASD services, the region of Metro Detroit exhibited a significant disparity in availability, such that wealthier suburbs had good availability of ASD agencies while few agencies were available in the poorer urban area. Thus, high population and low SES alone do not seem to determine the distribution of ASD agencies.

Conclusions: Knowing the landscape of ASD availability (and the specific areas that are particularly poorly serviced) gives service providers and healthcare planners the opportunity to advocate for increases in ASD services in these underserved areas. Additional services research is needed to identify system-level barriers contributing to disparate service availability. While addressing gaps in urban and rural regions may be difficult, use of evidence-based dissemination and implementation strategies may facilitate adoption and uptake of more nimble treatment options such as integration of behavioral health and primary care, school-based health centers, mobile autism clinics or telehealth services.[7-10]

300 **176.300** A Pilot Study to Enhance Psychologists' Delivery of Feedback during the Autism Spectrum Disorder Diagnostic Evaluation

R. Haine-Schlagel[1], *C. Corsello Orahovats*[2], *H. Gould*[3], *T. Holt*[4] *and L. Brookman-Frazee*[5], *(1)Child and Adolescent Services Research Center, San Diego, CA, (2)Division TEACCH, University of North Carolina, Chapel Hill; Chapel Hill, NC, Raleigh, NC, (3)UCSD, San Diego, CA, (4)Psychiatry, UCSD Psychiatry, San Diego, CA, (5)Psychiatry, University of California, San Diego, San Diego, CA*

Background: Serving children with Autism Spectrum Disorder (ASD) is a significant public health concern (CDC, 2014). Although up to 44% of children with ASD receive a comprehensive evaluation before age 3, up to 25% of children with ASD do not receive any services (Bowker et al., 2011; CDC, 2014). Researchers have suggested that tailoring the diagnostic evaluation feedback can lead to reducing time to parent initiation of services (Mandell & Novak, 2005; Zuckerman et al., 2016). To date, only one study has examined a training to practice delivery of an ASD diagnosis and found it helped trainees increase flexibility, attentiveness, and responsivity to parents (Kawamura et al., 2016).

Objectives: To develop and pilot a toolkit to improve and individualize psychologists' communication to families following an ASD diagnostic evaluation. Specific goals of this study are to: (a) examine psychologists' perception of feasibility, usefulness, acceptability and appropriateness of a toolkit for feedback in a community based clinic using mixed-method data; and (b) examine the impact of the toolkit on psychologists' perceptions and practice.

Methods: Seven psychologists at a regional children's hospital were recruited to participate in a toolkit training, and complete a 4-item "confidence in tailoring feedback" prior to and following the training in addition to a feedback survey two-months post-training and a ten-month follow-up interview. All participating psychologists were female and the majority were Non-Hispanic White. Interview data were analyzed using a Rapid Assessment Process (RAP; Beebe, 2001); open-ended survey responses were coded using an open-coding process (Haine-Schlagel et al., 2013); and survey responses (on a Likert scale from 1-strongly disagree to 5-strongly agree) were analyzed using SPSS. In addition, parents served by participating psychologists before and after toolkit training were asked about psychologists' use of key toolkit strategies.

Results: Psychologists responses to the feedback survey close-ended responses indicated: 1) very high training acceptability (M=4.70; SD=.39); 2) high toolkit feasibility (M=4.21; SD=.57)utility to increase parent readiness to act on recommendations (M=4.14; SD=.90), satisfaction (M=4.36; SD=.56); 5) appropriateness (M=4.50; SD=.50) and planned sustained use of the toolkit (M=4.43; SD=.54); and 3) moderate toolkit utility for tailoring evaluation feedback (M=3.89; SD=.48). Feedback survey open-ended responses indicated specific tools that were most useful.

For the second objective, only four providers completed the confidence items both before and after training and examination of the mean responses for each item indicate consistent trends in the expected direction (i.e., improved confidence after the training). Effect size estimates indicate that parents served after toolkit training reported that the psychologist was more likely to prioritize recommendations and provide clear guidelines for how to obtain the evaluation report than parents served before the training. Psychologist follow-up interview themes indicated sustained use of certain toolkit components but not always as intended.

Conclusions: Both quantitative and qualitative pilot data indicate that a toolkit to assist psychologists in tailoring their feedback and recommendations following an ASD evaluation is feasible, useful, acceptable, and appropriate and may impact psychologists' perceptions about tailoring the evaluation feedback process as well their feedback delivery practices.

301 **176.301** A Review of Family Navigation: An Exemplar for Children with Autism

E. Hickey[1], *N. A. Stadnick*[2], *J. L. Kuhn*[3], *S. Broder-Fingert*[1,4], *J. Goupil*[1], *A. Chu*[5], *J. E. Rosenberg*[1], *M. Augustyn*[1,4] *and E. Feinberg*[4,5], *(1)Boston Medical Center, Boston, MA, (2)University of California San Diego, La Jolla, CA, (3)Pediatrics, Boston Medical Center, Boston, MA, (4)Boston University School of Medicine, Boston, MA, (5)Boston University School of Public Health, Boston, MA*

Background: Significant disparities exist in access to diagnostic and treatment services for children with autism spectrum disorder (ASD), especially for low income, racial and ethnic minority families. *Family Navigation* (FN) is a promising intervention to address these disparities by reducing system and patient-specific barriers to accessing ASD diagnosis and treatment. FN is an evidence-based care management intervention delivered by a trained community health worker who assists families in overcoming barriers to accessing a defined set of services over a time-limited period. There is a growing evidence base for FN to accelerate the diagnosis of ASD and early intervention access. However, no published data exist on how best to deliver FN, which components are most critical (and for whom), and what strategies to employ for implementation (i.e., "core components").

Objectives: To review existing FN work and describe the core components of FN for ASD.

Methods: The research teams from four large studies (total N of children = 550) of FN for ASD completed the Template for Intervention Description and Replication (TIDieR) checklist to outline intervention components including: physical materials, who provided services, how/where /when/how often service was provided, tailoring or modification, and assessment of intervention fidelity and implementation. A qualitative synthesis of these TIDier checklists was used to determine the core components.

Results: Ten components were identified: (1) intensive training to navigators on motivational interviewing, navigation intervention, problem solving approaches, and ASD diagnostic and treatment services; (2) ongoing supervision and case review; (3) shared language and cultural concordance between the navigator and the family; (4) individual (navigator to family) face-to-face, phone, and email encounters, which occur in family's homes, clinic, or other community/service settings where the family requests support (e.g., Supplemental Security Income office); (5) identification of barriers to appropriate care (e.g., language, cultural beliefs, transportation, distrust/emotional barriers, medical system barriers, financial barriers); (6) creation of a family-specific action plan to improve access to care; (7) care coordination for the entire family and the provision of a necessary link to community-based resources; (8) emotional support throughout the entire process (i.e., from FN referral through access to ASD treatment up to 100 days); (9) checklist of key navigator tasks that are family-specific and vary in intensity based on each family's needs (e.g., helping to schedule appointments); (10) ongoing, systematic fidelity monitoring (e.g., Family Navigators audiotape one randomly selected session for each client; audiotapes are then reviewed by the FN supervisor and used to provide feedback on FN delivery)

Conclusions: Family navigation in the context of childhood ASD is designed to reduce the time to an ASD diagnosis and access to treatment, and mitigate racial, ethnic, and socioeconomic disparities in service access. Through a qualitative synthesis of large-scale studies testing FN for ASD, we identified 10 core components of FN training and treatment delivery. We will discuss the importance of each component and implications for future implementation research and practice of FN for ASD.

302 **176.302** Age at ASD Diagnosis and Influential Factors: A Meta-Analysis and Systematic Review for 2012-2018

M. van 't Hof[1,2], *I. A. van Berckelaer-Onnes*[3,4], *A. Daniels*[5], *M. Deen*[6,7], *H. W. Hoek*[8,9,10] *and W. A. Ester*[2,11,12], *(1)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, (2)Parnassia Psychiatric Institute, The Hague, Netherlands, (3)Sarr Expert Centre for Autism, Lucertis Child and Adolescence Psychiatry, Rotterdam, Netherlands, (4)Faculty of Social Sciences, Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (5)Simons Foundation, New York, NY, (6)Parnassia Psychiatric Institute, The hague, Netherlands, (7)Faculty of Social and Behavioural Sciences, Institute of Psychology, Methodology and Statistics Unit, Leiden University, Leiden, Netherlands, (8)Department of Epidemiology, Columbia University - Mailman School of Public Health, New York, NY, (9)Department of Psychiatry, University of Groningen - University Medical Center Groningen, Groningen, Netherlands, (10)Parnassia Academy, Parnassia Psychiatric Institute, Den Haag, Netherlands, (11)Department of Child and Adolescent Psychiatry, Curium-LUMC, Leiden University Medical Center, Oegstgeest, Netherlands, (12)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands*

Background: Between 1990 and 2012 the global mean age of ASD diagnosis was reported between 38 and 120 months. Although global measures take place to reduce the age at ASD diagnosis, the global current age of ASD diagnosis is unknown.

Objectives: To conducted a meta-analysis regarding the global average age at ASD diagnosis and a systematic literature review regarding influential factors on the age at ASD diagnosis between 2012 till 2018.

Methods: We performed a PubMed literature search with 'age' AND 'diagnosis' AND 'ASD' in title or abstract. We limited the search to studies published in English from January 2012 through February 2018 reporting the average age at ASD diagnosis of any ASD. Influential factors on the age of diagnosis were assessed from these identified studies. We conducted random-effects meta-analysis to assess the global mean age at ASD diagnosis. Also, we specified the mean age at diagnosis for study samples < 10 years of age so results can be interpreted within the scope of early detection.

Results: We found 40 studies reporting the average age at ASD diagnosis in 36 countries (n = 2141 215 individuals). Results show that the mean age at diagnosis (n=28 033 individuals) ranged from 29 to 571 months and meta-analysis show that the overall mean (95%CI) age at diagnosis was 55.5 (44.8;66.2) months. When studies were selected comprising children only <10 years of age (n=17 760 individuals), the mean age at diagnosis ranged from 30.81 to 74.7 months and meta-analysis showed that the overall mean (95%CI) age at diagnosis was 43.5 (40.0;47.0) months. Type of ASD diagnosis, ASD severity, additional diagnosis and region are the most frequently reported factors affecting the age at diagnosis.

Conclusions: Our systematic literature review and meta-analysis between 2012-2018 showed that the overall mean age at ASD diagnosis is 55.5 months, compared to the range of 38 and 120 months based on a literature review between 1990 and 2012. Although comparability of these outcomes is complex due to study design factors, these results indicate that although a younger age of diagnosis seems to be obtained, improvement in early detection of ASD should have constant attention.

303 **176.303** All Hands on Deck: Increasing Knowledge of Autism Signs and Symptoms By Evaluators in the Part C System Toward Earlier Detection and Referral for Early Intervention Services

J. L. Stapel-Wax[1], *N. Bond*[2], *E. Kaiser*[2], *M. Costo*[2] *and K. Guerra*[2], *(1)Emory University School of Medicine, Atl, GA, (2)Marcus Autism Center, Atlanta, GA*

Background:

Despite evidence that early intervention (EI) for Autism Spectrum Disorder (ASD) can improve language and behavior and optimize outcomes for children by making crucial differences in early brain development (Dawson et al, 2012), only a fraction of children with ASD are identified in early childhood (Baio et al, 2018). Standardized ASD screening procedures and knowledge are not yet in widespread practice in pediatric settings (Radecki et al 2011); however, implementation of these procedures community-wide is needed to address disparities in age of detection based on many factors (Giarelli et al 2010). In many communities, EI providers also lack sufficient training to recognize red flags for ASD (Zwaigenbaum et al, 2015; IACC, 2017).

Objectives**:**

Evaluators are among the first professionals to see children referred for delays and are in the pivotal position of using assessments and clinical judgment to refer children with developmental delays meeting criteria for services in the Part C system. This project aimed to increase evaluators' knowledge and comfort with early detection of ASD in infants and toddlers by providing access to an 8 hour web-based course and conducting three webinars to support participants' learning.

Methods:

This study examined the feasibility and impact of providing training to 20 EI evaluators on red flags for ASD in toddlers. The study utilized automated completion and mastery metrics as well as surveys on a Likert scale. Participants also provided text responses to reflect options not listed. This exploratory study examined demographics, education level, professional role, impact on knowledge and comfort with identifying ASD, willingness to discuss ASD with families, and satisfaction with the training.

Results:

- 20 EI evaluators represented 8 of 18 districts
- 3 districts served a highly populated metro area; 5 served rural areas .
- 75% MA degree; 25% BA degree
- 3 SLPS, 12 intake coordinators,13 special instructors. Several individuals held more than one role.
- 70% of participants participated in all three webinars.
    - 47% of participants completed all six modules
    - 37% of participants did not complete modules
    - 50% responded to both a pre- and post-survey.
        - From pre- to post, participants reported an increase in knowledge and confidence in:
            - describing red flags for ASD to families
            - answering questions about ASD
            - creating IFSP goals to address social communication deficits.
        - All participants reported that the webinars were relevant and engaging and that the best way to learn is through both online modules AND webinars

Conclusions:

Data gathered from participants indicated high satisfaction with the project and an overall increase in evaluators' confidence in identifying and describing red flags for ASD in young children. This data informs future collaborations in the community with the goals of supporting EI evaluators to deepen their knowledge of ASD in toddlers, their ability to describe red flags for ASD to families during the EI evaluation process, and building the capacity in the Part C system to identify and provide evidence-based intervention for children who are at-risk for autism. This project could easily be replicated statewide and child and family outcomes measured.

304 **176.304** An Integrated Health Care Model for Patients with Autism Spectrum Disorder

S. L. Jackson[1,2], ***E. Nozetz***[1,3], *A. Joseph*[1] *and T. Piscitelli*[1], *(1)Clifford Beers Clinic, New Haven, CT, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Pediatrics, Yale School of Medicine, New Haven, CT*

Background: More than 70% of children with Autism Spectrum Disorder (ASD) have a co-occurring psychiatric or medical condition, requiring frequent access of the healthcare system over a range of sub-specialties (Dang et al., 2017). Due to the complexity of navigating care for this population (Fig. 1), the majority of families with children with ASD are more likely to experience delays in care and lower satisfaction with the care they do receive (Kogan et al., 2008).

The Integrated Care Model involves a coordinated and co-located collaboration between primary care and mental health providers working together to care for the patient (Ader, 2015). Outcomes in the general population have demonstrated significant improvements in the mental

health of youth in an integrated compared to a standard setting (Asarnow et al., 2015), however there is a gap in the literature when it comes to patients with ASD.

Objectives: To develop, implement, and assess an integrated model of care within an existing behavioral health clinic focused on the care of individuals with ASD and other developmental disabilities with the aim of improving patient care and outcomes.

Methods: Development of the model to integrate medical services into the existing behavioral health clinic began in May 2018. To track client utilization a referral tracking system was built into the clinics Electronic Health Record system. A staff survey was designed to assess buy-in, feedback, and perceived needs/benefits of the introduction of the model. Additionally, the Parental Stress Index (PSI) and Youth Satisfaction Survey (YSS) were selected to assess the impact of the integrated model on the clients and their families. Integrated services began being offered at the clinic in August 2018.

Results: Over the past year, 245 individuals with ASD were seen at the clinic (82.9% male; age range 3-54 years, *M*=13.9, *SD*=7.45). Nearly half (48.8%) of clients who were assessed at intake reported concerns over additional health problems, with the most commonly reported related to speech problems, dental issues, asthma, and vision problems. Feedback from staff surveys suggest strong buy-in with 93% reporting that they were likely-very likely to utilize the new medical services. The pediatrician currently is on-site once a week to provide services and clinic staff are already regularly utilizing this resource for consultation on client issues. Additionally, monthly educational sessions are hosted by the pediatrician for the staff to discuss medical topics of interest. Data collection is ongoing and analyses on referrals, PSI, YSS, and staff surveys will be conducted to explore the impact of the introduction of the model on the clients.

Conclusions: Building on the current work of the clinic, the team is streamlining workflows, and incorporating systems for assessment of the impact of the model. Providing an integrated care model to families will allow them to receive efficient, coordinated and holistic care at one site. Should our integrated model prove effective at improving access to care and the quality of life of families impacted by ASD, we hope the integrated care model becomes a common practice for ASD clinics.

305 **176.305** Autism Parent Training in a Developing Country: A Public/Non-Governmental Organization (NGO) Partnership.

***P. Bahadursingh**, South West Regional Health Authority, Couva, Trinidad And Tobago*

Background:

Multidisciplinary support services for autism spectrum disorder are minimal in the public service and often inaccessible due to the high cost privately. Repeated advocacy efforts have also failed to impact significantly the public service provisions. The stark reality is that many families do not access basic services like speech therapy and occupational therapy. Many children do not receive adequate access to school placements.

Early detection and intervention is the way forward but in a developing country, impacting service provision is limited by resource challenges regarding funding, management, political will, infrastructure limitations, and limited human resources.

This project accessed funding from a NGO to train professionals within the public health system to provide parent training modules to parents in their service regions.

Objectives:

We studied the impact of a NGO sponsored training in providing training to parents of children with ASD.

Methods:

In March 2016, December 2016 and November 2017, a local Rotary Club, a Child Health Department of a tertiary institution, a Community Paediatric team in a Regional Health Authority (RHA) and a foreign university autism research and treatment centre came together to host autism parent training modules. Selected professionals from all five Regional Health Authorities in the country were invited to be trained. Parents from various public clinics were invited to attend. Eight modules were completed. Professionals trained then offered training to parents in their respective regions.

Results:

Within twenty four months subsequent to the initial training, sixty percent of the RHAs held some form of parent training for local families.

In one RHA, a child psychiatry team and a community paediatric team collaborated to provide parent training during afternoon sessions within working hours in a local health centre. Materials were provided through the RHA print centre. Light refreshments were sponsored by a drug company. Eight training sessions were carried out during the twenty four month period. On average thirty parents were invited for the training but the average attendance rate was 60% of parents invited. Initial feedback indicated that parents found the training beneficial. Data regarding the outcome after training is to be collected.

In another RHA, training was carried out in a local health centre for small groups of parents with positive feedback from parents. A medical officer teamed up with nurses in the health centre to provide the training.

In another RHA, an initial large group parent training session was carried out. Further sessions were not initiated.

Training was also provided in the context of clinical consultations in paediatric follow up clinics.

Conclusions:

In keeping with the United Nations mandate for upgrading services for Autism this Public/NGO partnership has served to improve capacity by empowering and training parents. Given the constraints, financial and otherwise, this type of partnership may be the way forward in developing countries. While the partnership has bolstered capacity, further supports and strategies beyond provision of initial training is necessary to achieve sustainable improvements in care within developing countries.

306 **176.306** Barriers to the Implementation of Effective Transition Services for Adolescents with Autism Spectrum Disorder

***L. Corona**, M. Rinaldi and K. V. Christodulu, Center for Autism and Related Disabilities, Albany, NY*

Background: In the years following high school, young adults with autism spectrum disorder (ASD) report lower rates of employment, post-secondary education, and independent living than do individuals with other disabilities (Newman et al., 2011). Though evidence-based practices

exist to support individuals with disabilities generally during the transition from high school to post-school education or employment, little research has focused on evidence-based practices specifically targeting high school students with ASD (Test, Smith, & Carter, 2014). Current literature summarizes recommended best practices for preparing adolescents with ASD for transition (e.g., Gerhardt & Lainer, 2011), yet these recommendations are implemented inconsistently at best (Carter et al., 2010). The present study utilized a qualitative approach to investigate barriers to the implementation of effective transition services for adolescents with ASD.

Objectives: The primary objective of the present study was to document barriers impacting the implementation of best-practice transition services for adolescents with ASD, from the perspective of multiple stakeholders. In particular, the present study sought to describe challenges unique to individuals with ASD during the transition period.

Methods: A series of focus group discussions were held to access the perspectives of parents of adolescents and young adults with ASD, as well as school and community professionals working with individuals with ASD. Focus groups were homogenous with respect to stakeholder group (i.e., parents, school professionals, community professionals). Focus group transcripts were analyzed using a constant comparative approach (Boeije, 2002), resulting in a series of themes representing an array of barriers to transition planning and transition services.

Results: Analysis of focus group transcripts yielded 21 separate themes. Nine themes were related specifically to challenges associated with core symptoms or associated characteristics of ASD, such as social challenges, independent living skills, and self-determination. Ten of the themes focused on challenges or barriers existing at the systems level, either within families, within school or agency systems, or in interactions among these systems. These included service availability and access, limited knowledge about ASD, and challenges finding appropriate employment. The remaining two themes highlighted the importance of interpersonal relationships and the challenge of burnout. Examining the frequency of references to specific themes across stakeholder groups indicated that similar patterns emerged in the discussions of parents, school professionals, and community professionals.

Conclusions: The barriers described by focus group participants answer not only the question "What interferes with the *implementation* of transition services?" but also the question "What barriers are transition services *not addressing* for individuals with ASD?" The implementation of best practice transition services is hindered by limited availability of such services, a lack of personnel to provide them, and uneven knowledge about ASD, among other challenges. However, there also do not exist sufficient services to address the full range of challenges associated with the characteristics of ASD. For instance, existing transition services typically do not include mental health services, instruction in independent living skills, or executive functioning strategies. As efforts to improve transition services and outcomes continue, it will be important to consider and address the barriers described by stakeholders.

307 **176.307** Behavioral Artistry: Identifying the Characteristics of Effective Therapists in the Applied Behavior Analysis Treatment of Autism

K. Callahan[1], *R. L. Foxx*[2], *S. M. Nichols*[1], *A. Swierczynski*[1], *S. Mehta*[3], *R. Sharma*[4], *X. Aerts*[1], *M. E. McComb*[1], *A. Donald*[1] *and G. Segal*[1], *(1)Kristin Farmer Autism Center, University of North Texas, Denton, TX, (2)Penn State University at Harrisburg, Harrisburg, PA, (3)Educational Psychology, University of North Texas, Denton, TX, (4)Rehabilitation and Health Services, University of North Texas, Denton, TX*

Background: Richard Foxx's article "Twenty-five years of Applied Behavior Analysis: Lessons Learned" summarized insights from decades of research and treatment in the field of ABA, concluding that the effectiveness of therapy may be negatively impacted by limited repertoires among today's behavioral interventionists. Foxx believes there are important differences in the outcomes of ABA treatment between persons who deliver services strictly in a traditional way ("Behavioral Technologists") and those who demonstrate a broader set of humanistic/interpersonal behaviors ("Behavioral Artists") including care, flexibility, optimism, and humor, among others. Our previous research standardized the reliable measurement of Foxx's Behavioral Artistry (BA) traits using Cattell's Sixteen Personality Factors (16PF) Questionnaire, and socially validated BA by demonstrating parents of children with autism significantly preferred descriptions of behaviors aligning with BA characteristics.
Objectives: The purpose of this study was to investigate differences in the quality of ABA treatment for children with autism when delivered by therapists who have higher or lower levels of Behavioral Artistry.

Methods: ABA therapists at a university-based autism center completed the 16PF questionnaire and were assigned an overall percentage of BA traits based on their corresponding 16PF scores. Therapists with the highest (75% or greater) and lowest (25% or lower) BA percentages were observed during multiple 10-minute videotaped DTT and NET therapy sessions. There were 13 therapists in both the High-BA and Low-BA groups. Foxx's characteristic "Likes People" subsumes a majority of the BA traits. Thus, Likes People was operationally defined, including four behavioral components: Pleasant Facial Expression, Positive Tone of Voice, Sustained Gaze (at client), and Body Position/Orientation. For each therapist, partial-interval recording (10-second intervals) was used to determine a percentage of occurrence for each behavioral component across three observations. Additionally, a subjective rating (0-100) of Likes People was scored by data collectors for each observation session. A percentage of Behavioral Technologist behaviors (defined as fidelity of implementation of trained components of DTT and NET therapy) was also scored. Differences by therapist gender, university major, number of months of experience, and type of therapy session were analyzed.

Results: Therapists in the High-BA group scored higher on all objective and subjective ratings of Likes People, and on Behavioral Technology, than those in the Low-BA group. Differences were statistically significantly higher *(p=0.05)* for Pleasant Facial Expression. Females scored higher than males in both groups. There were significantly fewer ABA majors in the High-BA group. Low-BA therapists had significantly more experience. Therapists in the Low-BA group scored lower on Positive Tone of Voice during NET sessions. IOA for Likes People interval scoring was 94.2% overall.

Conclusions: Therapists with higher levels of interpersonal behaviors associated with Behavioral Artistry were rated qualitatively better in their delivery of ABA treatment for children with autism, suggesting important implications for hiring, training, and supervising effective ABA interventionists. Hypothetically, therapists who are warm, attentive, creative, optimistic, and persevering will generate more positive outcomes for individuals with autism in schools, clinics, and homes. Future research should investigate whether High-BA therapists have better client outcomes and whether BA can be effectively trained.

308 **176.308** Caring for Children with ASD in Primary Care: Perceived Barriers and Needs for Support

M. O. Mazurek[1], *C. Harkins*[1], *J. Chan*[2], *R. A. Parker*[3], *K. Kuhlthau*[2], *F. Lu*[2] *and K. Sohl*[4], *(1)University of Virginia, Charlottesville, VA, (2)Massachusetts General Hospital, Boston, MA, (3)Biostatistics, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (4)Thompson Center for*

Autism, University of Missouri - School of Medicine, Columbia, MO

Background: Access to comprehensive, coordinated, and evidence-based healthcare is critical for children with autism spectrum disorder (ASD), particularly given their complex healthcare needs and co-occurring medical and psychiatric conditions. However, children with ASD experience greater unmet healthcare needs, higher healthcare costs, and worse access to specialty care than children with other special healthcare needs. Children with ASD from underserved populations face even greater difficulties accessing specialty care. Primary care providers (PCPs) are ideally positioned to address these disparities by offering consistent, timely, and culturally-responsive care for children in their own communities. However, many PCPs have difficulty providing evidence-based screening and management of children with ASD. A better understanding of perceived barriers and needs for support among PCPs would directly inform future efforts to enhance care for children with ASD within the primary care setting.

Objectives: To examine the perceived barriers and needs for support in providing care for children with ASD among a large geographically diverse sample of PCPs.

Methods: Data were examined from a multi-site study of a new PCP training program focused on caring for children with ASD. The sample included 114 PCPs caring for underserved children in 14 US states, including general pediatricians (n=82), internal medicine-pediatrics physicians (n=6), family medicine physicians (n=7), nurse practitioners (n=15), physician assistants (n=2), and other PCPs (n=2). At the baseline assessment (prior to participating in the 6-month training program), PCPs were asked to indicate the specific barriers they faced in caring for children with ASD in their practices (from a list of 10, which included an open-ended "other" option), and also responded to an open-ended text response question: "What do you need to improve care for children with autism in your practice?" Descriptive statistics were conducted to characterize the frequency with which specific barriers were endorsed. Qualitative methods were used to code and analyze the themes reported in open-ended responses.

Results: The most commonly endorsed barriers included lack of time (84%), lack of confidence in managing behavioral issues in children with autism (84%), and lack of knowledge about autism resources (80%). Many PCPs also endorsed lack of access to autism specialists (64%), lack of prior training in autism (57%), lack of confidence managing medical problems in children with autism (50%), and lack of knowledge about autism symptoms (30%). Fewer PCPs reported lack of support from administration (17%) or inadequate reimbursement (28%) as barriers. Qualitative analyses of perceived needs for support revealed six themes, the most common being need for additional resources (expressed by 48% of PCPs), desire for more knowledge and confidence (52%), and a need for greater access to diagnostic and behavioral specialists (25%).

Conclusions: PCPs commonly endorsed multiple barriers to caring for children with ASD. Many of the most commonly reported barriers related to needs for additional knowledge and training in how to manage and support children with ASD, suggesting a need for specific PCP training programs. Additional barriers suggest a need for enhancing the broader health system, including allowing for lengthier visits and improved reimbursement.

309 **176.309** Clinician Perspectives and Processes Impact Genetic Testing Completion in Autism: A Mixed Methods Survey

***N. Abreu**, M. Chiujdea and S. J. Spence, Autism Spectrum Center, Boston Children's Hospital, Boston, MA*

Background: Despite consensus guidelines that genetic testing should be offered to all patients with non-syndromic autism spectrum disorders (ASD), research shows low utilization rates for any genetic test (41-51%), and lower (13-20%) for chromosomal microarray (CMA). In 2013, the Boston Children's Hospital Autism Spectrum Center instituted practice guidelines calling for Fragile X and CMA testing for all children with non-syndromic ASD. Data from February 2015 through January 2016 demonstrated that only 40% of our patients with a new ASD diagnosis were undergoing CMA despite these guidelines.

Objectives: To better understand the low rate of completion of genetic testing, we conducted an anonymous mixed methods survey of providers in the Boston Children's Hospital Autism Spectrum Center about their perspectives on genetic evaluation in ASD, current processes and barriers to testing.

Methods: A survey was sent electronically to 59 providers in the Department of Neurology and the Division of Developmental Medicine at Boston Children's Hospital. Nurse practitioners, neurologists, psychologists, developmental-behavioral pediatricians and neurodevelopmental disabilities specialists who perform diagnostic evaluations in the Autism Spectrum Center were included. Trainees in clinical psychology, developmental-behavioral pediatrics and neurodevelopmental disabilities were also included. Questions covered the areas of current practice, knowledge gaps, and obstacles clinicians face.

Results: Thirty providers completed the survey for a 50.8% response rate, with equal representation across Neurology and Developmental Medicine. The majority of respondents were attending physicians (n=15, 50.0%), followed by physician trainees (n=8, 26.7%), attending psychologists (n=5, 16.7%) and nurse practitioners (n = 2, 6.7%). These providers were performing new diagnoses frequently, with 86.7% of respondents diagnosing ASD at least 1-3 times per month. All clinicians recommended genetic testing often or always, and 69.0% believed that families are often interested in genetic testing (compared to 3.4% = "always," 27.6% = "sometimes").

The most common reason providers did not recommend genetic testing for ASD was forgetfulness (n=7, 23.3%). While 96.7% of respondents endorsed discussion of the importance of testing with families, only 40% affirmed they typically discuss testing methods like identification of deletions/duplications on CMA, and just 3.3% endorsed explanation of the possibility of detecting consanguinity with single nucleotide polymorphism-based CMAs. In terms of process gaps, for patients initially denied coverage, some providers (19.2%) did not pursue genetic testing further, while others (30.8%) referred families to the Genetics Division to resolve insurance coverage issues. One major barrier appeared to be prior authorization for genetic testing, with 52.0% of providers reporting being uncomfortable with the process. Free-text comments on barriers to genetic testing centered on the "confusing and difficult" insurance authorization process and need for additional resources.

Conclusions: Providers across Neurology, Psychology and Developmental Pediatrics are on the front lines of the initial genetic evaluation of children with ASD. We identified variability in provider self-reported comfort, counseling and processes, which impact which children with ASD complete standard-of-care genetic testing. Further work and resources are required to generate a simple centralized system to tackle this complex but surmountable challenge for providers and families alike.

310 **176.310** Development and Psychometric Testing of the Healthcare Provider Self-Efficacy Scale – Adult Autism

***C. Nicolaidis**[1], D. Raymaker[1], S. K. Kapp[2], M. Weiner[3], C. Kripke[4], L. A. Croen[5], G. Schneider[6], M. L. Massolo[5] and H. J. Cerros[5], (1)School of Social Work, Portland State University, Portland, OR, (2)University of Exeter, Exeter, United Kingdom, (3)Center for Health Services and Outcomes Research,*

Indiana University, Indianapolis, IN, (4)Family and Community Medicine, University of California San Fransisco, San Fransisco, CA, (5)Division of Research, Kaiser Permanente, Oakland, CA, (6)Regional Research Institute, Portland State University, Portland, OR

Background: A growing number of studies show that autistic adults experience significant healthcare disparities and that healthcare providers are ill-equipped to provide high-quality care to adult patients on the autism spectrum. Interventions to improve care must be informed by providers' specific training needs which may be assessed using measures of providers' self-efficacy. However, there are no existing validated instruments to assess provider self-efficacy in caring for adult patients on the spectrum.

Objectives: Develop and psychometrically test the Provider Self-Efficacy Scale - Adult Autism, a measure of providers' self-efficacy in providing healthcare to autistic adults.

Methods: We used a community-based participatory approach throughout the project, in partnership with academic researchers, autistic adults, supporters, and healthcare providers. We used our prior qualitative research and our team's expertise to create a 1-page questionnaire for primary care providers. The new self-efficacy scale includes 6 items prompting providers to rate their confidence in several aspects of providing care to adult patients on the autism spectrum. Response options use a 5-point Likert scale (1=not at all confident to 5=very confident). The 6 items were dichotomized at 4-5=high confidence and totaled (range 6-30). The survey also includes 2 items on how challenging or rewarding providers felt it was to provide high-quality care to adults on the autism spectrum (0=not at all to 10=extremely) and 7 items on demographic characteristics, training, and experience. We surveyed 143 primary care providers from 8 primary care clinics in Oregon and California, USA. Approximately half practiced internal medicine and half practiced family medicine. We assessed the self-efficacy scale's internal consistency reliability using Cronbach's alpha and convergent validity using pair-wise correlations and t-tests.

Results: The Provider Self-Efficacy Scale-Adult Autism had good internal consistency reliability with an alpha of 0.87. It showed strong convergent validity, as follows: Participants who had provided care to 6 or more autistic adults had higher self-efficacy scores than those with less experience (mean 19.8 vs 17.6, p=0.006). Self-efficacy was positively correlated with providers' ratings of how rewarding it is and negatively correlated with ratings of how challenging it is to provide care to adults on the spectrum (r=0.24, p=0.005; r=-0.5, p<0.0001, respectively). A minority of providers reported high confidence in: communicating with patients (25%); performing physical exams or procedures (43%); accurately diagnosing and treating other medical issues (40%); helping patients stay calm and comfortable during visits (38%); identifying accommodation needs (14%); and making necessary accommodations (16%). There was no difference in self-efficacy score by provider gender, degree (MD/DO vs NP/PA), specialty, or training status. There was a slight positive association between self-efficacy score and provider age (r=0.17, p=0.04).

Conclusions: The Provider Self-Efficacy Scale-Adult Autism demonstrated strong internal consistency reliability and convergent validity. Providers showed low confidence in all aspects of providing care to autistic adults. Training needs may be highest in the areas of communicating with patients and identifying and making necessary accommodations. Future research is needed to validate this scale further and to understand how to meet providers' training needs most effectively.

311 **176.311** Early Intervention ASD Practices through Part C Systems: Results from a Nationwide Inquiry

A. B. Barber[1]*, A. Belew*[2] *and C. McGovern*[2]*, (1)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (2)University of Alabama, Tuscaloosa, AL*

Background: Part C of IDEA federally mandates that early intervention is provided to children under three years of age in order to enhance the development of infants and toddlers with disabilities, reduce educational costs, and enhance the capacity of families to meet their child's needs (IDEA, 2004). Governors determine which state agency administers the program. These agencies, guided by the Interagency Coordinating Council, determine eligibility including whether children at risk for disabilities, including Autism Spectrum Disorder (ASD), are served. Early interventions for children with suspected or confirmed ASD should address core and associated features through evidence-based Naturalistic Developmental Behavioral Interventions (NDBIs; Schreibman et al., 2015) that actively involve caregivers (Zwaigenbaum et al., 2015). However, community agencies often do not have the accessibility to ASD specific interventions and thus families are not recipients of these practices (Hume et al., 2007; Stahmer et al., 2005; Siller et al., 2013).

Objectives: To evaluate Part C practices across all 50 states regarding management of children with ASD.

Methods: Agency administrators within the state agency that determines intervention eligibility were contacted via phone and/or email. They were asked three questions about treatment dose, whether a specific method(s) of intervention was recommended, and whether Applied Behavior Analysis was provided through Part C. They were also encouraged to provide additional comments, challenges, or state-specific issues regarding treatment provision for children with ASD. Responses were entered into a database so descriptives could be calculated and comments could be evaluated to detect themes.

Results: To date, agency administrators from 27 states have responded. Dose ranged from 30 minutes per week to 25 hours per week. Eleven states recommended a specific method. Reported recommended methods included ABA (4 states), Floortime (3 states), Pivotal Response Training (2 states), and the Early Start Denver Model (2 states). Two states did not recommend a particular method, however they did refer clients and providers to the evidence-based practices identified in the National Standards Project (NAC, 2015). Two broad themes emerged within open comments: Medicaid waiver and Individualized Family Service Plan (IFSP). State guidelines relative to Medicaid waiver often influenced whether a Part C program recommended ABA services or other supplemental interventions. Dose and method were frequently determined by the IFSP, as intended by law. Twelve state agencies indicated that they provide ABA services through Part C or refer families for ABA services through the Medicaid system.

Conclusions: Part C early intervention practices for children with ASD vary widely across the 27 states analyzed for the current proposal. However, the IFSP was consistently used to determine dose and method. Funding mechanisms, primarily Medicaid, was frequently referenced relative to supplemental (ABA) interventions. Two NDBIs (PRT and ESDM) were recommended by four of the 27 states (15%). These preliminary findings provide insight into community early intervention practices and highlight the research to practice gap highlighted by previous studies (Dingfelder & Mandell, 2011). These findings also provide researchers with a clear picture of real-world early intervention practices and highlight opportunity for community based research. Data collection is ongoing.

312 **176.312** Effective Methods for Increasing Gesture Use for Children with ASD

J. R. Miller *and A. B. Barber, Communicative Disorders, University of Alabama, Tuscaloosa, AL*

Background:
Gesture development, use, and repertoire differ in young children with ASD (Manwaring et al., 2018 and Watson et al., 2013). Gestures play a fundamental role in social interaction and therefore are often an important intervention outcome in early interventions. Ingersoll (2006) taught imitation and spontaneous use of descriptive gestures in young children with autism using a naturalistic behavioral intervention and found all participants increased their imitations of gestures. Techniques used included RIT (reciprocal imitation training) which is a naturalistic intervention with the combinations of incidental teaching, milieu teaching, and pivotal response training. Ingersoll (2010) studied the impact of object and gesture imitation training on language use in children with ASD and found that teaching gestural imitation training alongside object imitation training lead to higher rate of language use than just object imitation alone. Cardon (2012) taught caregivers to implement video modeling imitation training via iPad for their children with autism and found all participants demonstrated increases in the level of imitation and made gains in expressive language. These are two of many intervention methodologies that teach gestures, what's left unknown is a comparison of those interventions to establish which are effective. While the previous research indicates ample evidence of what gestures look like, and their relationship to social communication, there is little evidence of what methods are most effective for reaching these gestures and which methods are most often used by practioners.

Objectives:

1. To evaluate which methods are most effective for increasing gestures use; and 2. To survey practicing speech language pathologists to determine which methods are most frequently used to teach gestures to young children with ASD.

Methods:

An evidence-based systematic review of literature is currently being completed. Methods were considered effective if gesture use was a dependent variable and increased post intervention.

The second step of this research study was to survey practicing Speech-language pathologists regarding their methods used for teaching gestures. Pending human subjects board review, the three question survey will be distributed through the American Speech-Language-Hearing Association (ASHA). The survey asks questions such as what methods are being used during intervention, what methods have been effective in teaching gestures, which methods have been ineffective, how have these methods effected social communication?

Results:

Based on established criteria, 80 articles were initially included that used a specific methodology to teach gestures to children with ASD under 5 years of age. Articles were summarized and analyzed for information pertaining to methods currently being taught and their effectiveness not only in teaching gestures to children with ASD.

Conclusions:

Preliminary findings support Naturalistic Developmental Behavioral Interventions (Schreibman et al., 2015) as the most effective method, along with an emphasis on imitation. Imitation includes techniques such as: RIT (reciprocal imitation training) and VMIT (video modeling imitation training). Parent implemented trainings incorporated within the methods being used are crucial to the effectiveness of the therapy process as well.

313 **176.313** Evaluation of Autism Training for Parents in Dhaka, Bangladesh

ABSTRACT WITHDRAWN

Background:
Institute of Paediatric Neurodisorder and Autism (IPNA), Bangabandhu Sheikh Mujib Medical University (BSMMU) at Dhaka, Bangladesh arranged early intervention and home management training for parents of children with Autism.

Objectives:

Evaluating the ASD (Autism Spectrum Disorders) child's parent's knowledge, experience after diagnosis of their child's ASD, management techniques before and after training on early intervention and home management in a specialized center.

Methods:

It was a comparative study. The study was conducted among 34 parents of ASD children with two different evaluation sheets. A training was conducted for two days in four sessions with PECs, ABA methods and different culturally adapted structured methods with hands-on exposure by experienced trainers. An evaluation sheet was collected before the training conducted and another one collected after the training was completed.

Results:

Before the training programme it was observed that most of the parents had known very little about Autism but they except their ASD children warmly. Most of them didn't know scientific ways of management of their children or how to behave with them. In that training parents were learned about what autism mean and ASD children management at home by their daylong activities. The training was conducted for two days in four sessions with Picture Exchange Communications (PECs), Applied Behavior Analysis (ABA) methods and different culturally adapted structured methods with hands-on exposure. After the training every participants wrote down their experiences in an evaluation form. Observing the after evaluation form it was clear that their understanding level about Autism was increased and they were interested to work scientifically with their ASD child.

Conclusions:

Most of the parents wanted to attend that type of parents training for long time and frequently.

314 **176.314** Evaluation of a Certified Autism Peer Support Service Model: Implementation Challenges and Successes

L. Shea[1], *K. Croce*[2], *K. Jackson*[3], *K. Kaplan*[3], *M. Y. Wong*[2] *and V. Paradiz*[4], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (3)Community Behavioral Health, Philadelphia, PA, (4)Valerie Paradiz LLC, Boulder, CO*

Background: The growing and underserved population of adolescents and young adults with autism faces a need for innovative, effective service models and employment opportunities. To meet this need, Philadelphia is implementing a new peer support model for transition-aged youth and young adults with autism. Certified peer support service models utilize individuals with 'lived experience' who receive training to support their peers in navigating services and other daily living activities and needs. Certified peer support service models have a robust evidence base in veteran[1-3] and mental health[4-6] populations, and a limited evidence base has found initially promising results from peer support services implemented for children and adults with autism. One study reviewing peer support among young children with autism found that, across single-case experimental design studies, young children with ASD across a range of presentations benefited from peer autism-specific support.[7] Published research has also focused on the use of peer support for children with autism in school settings among children, and found that it was effective in promoting peer engagement.[8] No research has been conducted on peer support services among adolescents and young adults with autism. The launch of peer support services in Philadelphia represents an opportunity to evaluate this service model in a large, diverse US city.
Objectives: The evaluation of the certified peer support service in Philadelphia will focus on changes in employment status, social and communication measures, and self-reported quality of life measures. A secondary outcome of the evaluation to shape policy and programs moving forward will be qualitative feedback from certified peer specialists with autism delivering the peer support services on their experience.

Methods: A battery of instruments capturing self-reported demographic information, employment status, social responsiveness, and quality of life measures will be completed pre- and post-service implementation by both the certified peer specialists delivering the service and the individuals receiving the peer support service. A focus group of individuals delivering the 12-week peer support service will also be conducted after completion.

Results: Certified peer support services are scheduled to launch in Philadelphia in early 2019. Certified peers will receive required training and complete both the pre- and post-service measures. Individuals receiving the peer support service will also complete both pre- and post-service measures. Immediately following the conclusion of service delivery, certified peers will also participate in a focus group to inform continuing service design and delivery. Results from these efforts will be presented from both quantitative and qualitative analysis.

Conclusions: Certified peer support services offer an innovative opportunity for individuals with autism to receive needed support through service navigation and the life course trajectory. Certified peer support services also present new opportunities for employment, and initial research suggests these services are effective in children and adults. The application of certified peer support services to youth and young adults in Philadelphia represents a potentially replicable service model implemented through Medicaid.

315 **176.315** Evaluation of a Community-Based Autism Clinic

J. S. Singh[1] *and L. Rubin*[2]*, (1)Georgia Institute of Technology, Atlanta, GA, (2)Pediatrics, Morehouse School of Medicine, Atlanta, GA*

Background:
Community-based autism clinics that serve primarily low-income, minority, and underserved populations are limited in the U.S. despite evident disparities to diagnosis and services based on race, ethnicity, and social class. To address the needs of underserved children with autism and their families in Atlanta, Georgia, the Autism Clinic at Hughes Spalding Children's Hospital, an affiliate of Children's Healthcare of Atlanta (CHOA), was established in 2002. The Autism Clinic provides a comprehensive continuum of autism services by offering one full day of multi-disciplinary services and a half-day of limited services per week from a range of professionals, including a developmental pediatrician, nurse practitioner, and a speech and occupational therapist. When needed, the clinic utilizes a CHOA language interpreter, social worker, nutritionist, nurse navigator, and/or special education specialist.

Objectives:

The purpose of this study is to evaluate the quality of care provided by the Autism Clinic at Hughes Spalding Children's Hospital in Atlanta to identify strengths of this model of care and areas for improvement.

Methods:

We conducted a Quality of Care Survey (53 item questionnaire plus demographics) with caregivers who utilize services at the Autism Clinic to evaluate three levels of care: Access to Care; Family Centered Care; and Care Coordination, as well as overall level of satisfaction with the range of services received at the clinic. See Table 1 for caregiver demographics.

Results:

Caregivers were most satisfied with various components of Family Centered Care, including providers spending enough time, listening carefully, encouraging questions, and offering specific information needed (91%, 99%, 96%, 96%, respectively). Caregivers where less satisfied with the time to first appointment (Average = 127 days) and access to services outside the clinic (78% of participants were usually, always or sometimes frustrated with accessing autism services). Overall, caregivers were satisfied with the diagnosis process, how the diagnosis was communicated, referrals provided, follow-up services, and range of services offered at the clinic (See Figure 1).

Conclusions:

We identified strengths in the quality of care offered by the Autism Clinic at Hughes Spalding Children's Hospital, including various components of family centered care and the overall experience of the diagnosis process. These strengths support the multi-disciplinary model provided by the Autism Clinic; a model of care particularly effective for underserved families because they are able to see four or more different providers in one visit. However, there are needed areas of improvement since 43% of families did not feel prepared for the first visit. We recommend the development of a bilingual information sheet about the types of providers and services offered at the clinic and what to expect during the initial visit. Parents also indicated that they did most of the care coordination for their child (71%). To help navigate the coordination between various autism providers, we recommend a designated autism clinic care coordinator, a specialist that works with Medicaid systems of care, and a parent advocate who can help meet the diverse needs of underserved families.

316 **176.316** Examining Navigational Support for Children with ASD and Their Families

D. B. Nicholas[1]*, L. Lach*[2]*, R. Zulla*[3] *and A. M. Filipe*[4]*, (1)University of Calgary, Edmonton, AB, Canada, (2)Departments of Pediatrics and Neurology/Neurosurgery, Faculty of Medicine, McGill University, Montreal, QC, Canada, (3)School of Public Health, University of Alberta, Edmonton, AB, Canada, (4)Centre for Research on Children and Families, McGill University, Faculty of Arts, Montreal, QC, Canada*

Background: There are urgent calls for integrated services and responsive navigation networks for individuals with ASD and their families. To our knowledge, no other initiative has systematically examined ASD-based navigational support networks across jurisdictions, with a robust research approach.

Objectives: The objective of this study was to (i) describe existing and desired yet absent elements of navigational support for children with ASD and their families and thus unmet needs, (ii) identify evidence-informed navigational practices and frameworks, and (iii) evaluate navigational processes in regional sites, consisting of three diverse Canadian jurisdictions (Edmonton (AB), Vancouver (BC), Whitehorse (YT)). Key questions addressed were: (i) what are evidence-informed navigational approaches relevant to ASD, (ii) what are facilitating and streamlining processes of navigation, and (iii) what is the scope and impact of navigational resources working together to offer timely and more equitable service access to individuals with ASD and their families. Interdisciplinary and cross-sectoral partners in this study include 60 community organizations/representatives.

Methods: This study builds on a collective framework methodology that incorporates mixed methods and participatory action research approaches. Organizational sectors represented comprise a range of stakeholders including self-advocates and advocacy groups, parents and families, government ministries, not-for-profit entities, service providers, and other inter-sectoral representatives. A scoping review and interviews were used to document the full range of navigational processes – from models and outcomes to lived experiences.

Results: In our initial scoping review, 2,044 peer-reviewed studies were retrieved, with 385 studies meeting initial screening criteria and 108 studies ultimately meeting inclusion criteria for full article review and synthesis inclusion. Corroborative primary interviews and focus groups were conducted with multiple stakeholders: self-advocates (n=15), family members (n=19), and service provider/advocate stakeholders (n=52). Jurisdictional models of navigation, as depicted by primary and secondary data analysis, discourage a 'one-size fits all' approach to service navigation in ASD. Findings support a systems-relevant and integrated network of navigational supports that are grounded in open channels of communication and iterative, family-oriented, community-directed design features. Such program characteristics are reported to foster proactive and reflective responsivity to the diverse service needs of individuals with ASD across the lifespan. Such guiding parameters reflect inter-agency, cross-ministerial, and cross-sectoral linkages.

Outcomes/Impacts: Navigation is documented to entail: case identification, need determination, identification of barriers to timely care, targeting of barriers for ameliorative change, facilitation of access to care, and systematic evaluation. Various levels and 'sectors' of navigational support have been determined to include: prevention; universal supports; specialized services; complex care; and urgent care. Needs of individuals with ASD and their families – requiring navigational support – are demonstrated within multiple 'life trajectory' pathways: transitions across the lifespan, community participation/engagement, family well-being, navigation across the continuum of care, safety in one's neighborhood, housing security, and personal health and mental health.

Conclusions: Family navigation is experienced differentially, with outcomes that reflect and impact individual and family quality of life. Effective navigation services can advance integrated, coordinated, seamless care and timely follow-up.

317 **176.317** Examining the Sustained Use of a Cognitive Behavioral Therapy Program for Youth with Autism Spectrum Disorder and Co-Occurring Anxiety

K. Pickard[1], *R. E. Boles*[2], *A. Blakeley-Smith*[3], *L. G. Klinger*[4], *A. Keefer*[5], *A. Duncan*[6], *S. E. O'Kelley*[7] *and J. Reaven*[1], *(1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)University of Colorado School of Medicine, Aurora, CO, (3)Univ. of Colo. Denver-JFK Partners, Aurora, CO, (4)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (5)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (6)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (7)University of Alabama at Birmingham, Birmingham, AL*

Background: Children and adolescents with autism spectrum disorder (ASD) are at high risk for developing co-occurring anxiety. In response to this concern, researchers have adapted cognitive behavior therapy (CBT) for youth with ASD. Results of a number of randomized controlled trials have demonstrated significant reductions in youth anxiety following CBT participation when it is delivered within controlled research settings. Although promising, only a handful of studies have examined the effectiveness of CBT programs when implemented within community settings and even fewer have examined the sustained use of CBT programs in community settings after implementation efforts have ended.
Objectives: The present study is a follow-up to an initial NIH-funded implementation trial that examined both implementation outcomes and youth treatment outcomes in response to an evidence-based, group CBT program for youth with ASD and co-occurring anxiety (i.e., Facing Your Fears (FYF); Reaven et al., 2018). This study aims to understand: 1) the percentage of clinicians who continue to use FYF four years following the implementation trial; 2) adaptations that have been made to FYF in order to sustain its fit within community settings; and 3) factors that influence clinicians' sustained use of FYF.

Methods: 34 clinicians working with youth with ASD (Mean age = 34 years; 94% female, 88% White) initially implemented FYF across four university clinics as part of the initial implementation trial (Reaven et al., 2018). A comprehensive, mixed-method survey will be sent to clinicians asking them whether they still use FYF in any capacity, in addition to questions regarding: 1) adaptations they have made to FYF (Stirman et al., 2017); 2) barriers and facilitators to the sustained use of FYF; and 3) strategies used to train new clinicians in using FYF. Participants will also complete quantitative measures of CBT knowledge, attitudes towards evidence based practices (EBPAS; Aarons, 2004), and organizational cultural and climate (ORC; Lehman et al., 2002).

Results: Based on well-established frameworks of sustainability (Chambers, Glasgow, & Stange, 2013), we expect that providers who continue to use FYF have made a number of adaptations to the program to support its fit within their community setting (e.g., adaptations to program length, session duration, and core components implemented; Stirman et al., 2017). We also expect that providers will identify key factors that influence their sustained use of FYF, including their attitudes, self-efficacy, organizational climate, and external funding.

Conclusions: Results from the present study will be critically important to better understand the barriers and facilitators to the sustained use of EBPs for ASD in community settings. Doing so will address critical gaps within the ASD field, as the absence of sustained EBP use may signal gaps in proactive implementation efforts and/or the fit of EBPs within community settings on a long-term basis.

318 **176.318** Experiences with Family-Centered Care Among Parents with Concerns about Autism Spectrum Disorder or Developmental Delay in Their Toddlers

C. C. Dick[1], *L. V. Ibanez*[2], *T. DesChamps*[1], *H. N. Hannah*[1] *and W. L. Stone*[1], *(1)Psychology, University of Washington, Seattle, WA, (2)UW READi Lab,*

Seattle, WA

Background: Family-centered care (FCC) is an approach to healthcare that considers the needs and priorities of the whole family; as such, it has been associated with increased parent satisfaction, decreased parent stress, and improved child outcomes (Rosenbaum et al., 1998). Accessing FCC may be of particular importance for families of children with ASD, given the children's complex healthcare needs and the parents' high levels of stress (Hayes & Watson, 2013). This study compares experiences of FCC across two groups of parents: those with concerns about autism for their toddlers (ASD) and those concerned about other developmental issues (DEV). In addition, we compare experiences with FCC across two systems of care frequently accessed by both groups: primary care and early intervention.
Objectives: (1) To examine whether parents who are concerned about ASD for their toddlers differ in the components of FCC they experience compared with families who have DEV concerns; and (2) to examine whether parents' experiences with FCC differ between their primary care providers (PCPs) and early intervention (EI) providers.

Methods: Participants were 59 families, 37 with ASD concerns (including 5 with an ASD diagnosis) and 22 with DEV concerns. Groups did not differ on any key child or parent demographic variables, including age of child in months (ASD: *M*=28.03, DEV: *M*=25.77). The *Measure of Processes of Care* (MPOC-20; King, King, & Rosenbaum, 2004) was completed by parents to assess five domains of FCC: Enabling and Partnership (EP), Providing General Information (PGI), Providing Specific Information (PSI), Coordinated and Comprehensive Care (CCC), and Respectful and Supportive Care (RSC). All families completed the MPOC-20 for both their PCP and EI provider. A 5(Subscale) x 2(Concerns group) x 2(Provider type) mixed design ANOVA was used and Bonferroni adjustments were applied to correct for pairwise comparisons.

Results: A significant interaction between MPOC-20 Subscale and Concerns group (F=3.744, p=.019) was followed by planned comparisons (Figures 1a and b). The ASD Concerns group reported: (1) significantly higher levels of RSC than EP, PGI, and PSI, but comparable CCC; (2) significantly lower levels of PGI relative to the other 4 scales; and (3) PGI levels that tended to be lower than those in the DEV group (p=.069). In contrast, comparable levels across the FCC subscales were found for the DEV group. Planned comparisons between Concerns group and Provider type revealed significantly higher ratings for EI providers than PCPs for the ASD concerns group only (EI: *M*=5.309, PCP: *M*=5.865, p=.005).

Conclusions: While both groups of parents reported high levels of comprehensive and respectful care, the ASD Concerns group experienced more inconsistency in FCC across domains. Parents with ASD concerns assigned lower ratings of general information provision relative to other FCC domains, and higher ratings of respectful and supportive care relative to information provision and enabling/partnership. In addition, the ASD concerns group, but not the DEV concerns group, provided higher ratings of FCC for EI providers than for PCPs. These results have potential implications for improving the experience of parents of children with ASD concerns within the healthcare system.

319 **176.319** Increasing Access to Autism Spectrum Disorder Diagnostic Consultation in Rural and Underserved Communities: Streamlined Evaluation within Primary Care

J. F. Hine[1]*, W. B. Allen*[2]*, A. Zawoyski*[3]*, B. Browning*[3]*, A. Swanson*[4] *and Z. Warren*[1]*, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Cherokee Health, Talbott, TN, (3)Cherokee Health Systems, Knoxville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN*

Background: With the increasing prevalence of autism spectrum disorder (ASD) and wide-spread delays for diagnostic evaluations and initiation of services, there is a growing need for novel systems of triage and care for children with ASD and their families. To combat growing disparities within rural and underserved communities, integration of behavioral-health services within primary care settings is often the preferred service model. In prior work, we embedded ASD consultation and support clinics within our medical center's primary care clinics. This change resulted in dramatically reduced waits for diagnostic consultation and follow-up. Many young children with ASD (and those without) were identified using a streamlined diagnostic model involving diagnostic interview, standard ASD rating scales, and the Screening Tool for Autism in Toddlers (STAT). These findings supported preliminary feasibility, accuracy, and clinical utility of this embedded streamlined assessment model that resulted in accurate diagnostic decision making, high levels of family/provider satisfaction, increased show rates, dramatic reductions in wait times, and reductions in referrals to an overtaxed tertiary diagnostic center.
Objectives: The present study investigates the impact of generalizing this model to a larger network of integrated primary care clinics located in the eastern region of our state with a largely rural and underserved catchment. This study extends previous work by providing data pre/post implementation of the streamlined model across a range of clinics, as opposed to comparing wait time reductions to local norms. This study also allowed us to study the impact of the embedded model when implemented by multiple clinicians across multiple primary care clinics that provide healthcare to rural and underserved communities.

Methods: Eighty children between the ages of 19 and 47 months old were seen across five different clinics. The participants were divided into four groups based on their status as primary care patients and whether they received an evaluation before or after implementation of the streamlined model. Data were collected via chart review from the electronic health record.

Results: Implementation of streamlined model resulted in a significant decrease in latency to diagnostic conclusion from a mean of 144.7 days to 49.9 days. Children were likely to experience a greater reduction in wait times if they were a primary care patient (mean reduction of 120.5 days) versus a non-primary care patient (mean reduction of 69.1 days). Lastly, data suggest that on average, diagnostic decisions were provided 1 month earlier in age post-implementation of streamlined model.

Conclusions: Results show significant reduction in wait times for ASD diagnostic decisions across both primary care and non-primary care patients. With implementation of the streamlined model, families had to wait an average of 95 days less than families not having access to the streamlined model. By reducing waits and identifying concerns more efficiently, we may increase the ability of families to access early intervention and support services as well as prepare them for the school-age transition at 3 years.

320 **176.320** Training Medical Providers to Care for Patients with ASD: Autism in 3-D

J. Harris[1]*, A. Robertiello*[2]*, H. Spiegel*[3] *and C. Sanpietro*[4]*, (1)Children's Specialized Hospital, Mountainside, NJ, (2)Autism, Children's Specialized Hospital, Mountainside, NJ, (3)Long Term Care, Children's Specialized Hospital, Mountainside, NJ, (4)Medical, Children's Specialized Hospital, Toms River, NJ*

Background: The social communication, restricted interests and repetitive behavior deficits that are core features of ASD may create challenges for patients, families and health care providers during routine and sick health visits as well as during emergent or acute medical care. In addition, ASD is often associated with medical and mental health co-morbidities and/or safety risks, which may further increase the need for medical visits beyond those of typically developing peers.

Objectives: To create multi-dimensional training and resources to improve the knowledge, comfort and effectiveness of medical providers in caring for patients with ASD in the medical setting.

Methods: Medical providers in a large health system were surveyed regarding their knowledge, comfort and concerns related to treatment of patients with ASD. Specific issues and scenarios were also solicited to help design training. Trainings were developed and implemented with varied audiences including primary care and acute care nurses, pediatric residents and pediatricians, inpatient multidisciplinary pediatric chronic illness management team, other service providers, and families. Resources developed included patient health and wellness passports, visual schedules, pictorial social narratives, and sensory toolkits.

Results: Baseline concerns included how to identify patients with ASD, handling communication and behavioral challenges, how to modify medical education for the patient, and coordination of care.

Five workshops were highlighted. For four of the five, training was provided by a multidisciplinary team which included psychologists, behavior analysts, parents, and nurse practitioners. The fifth workshop was provided by a psychologist. Participants reported improvements in knowledge and comfort in providing care, and improved ability to recognize individual/family strengths and challenges. The chronic illness management team successfully adapted their patient goals and training materials to better match patient skill level and learning style. One year follow up data for the nursing workshop will be reviewed to examine long-term impact. As a result of the trainings, one hospital initiated a system-wide process for identifying, preparing for and addressing needs of patients/families and staff.

Conclusions: Given the prevalence of ASD, nearly all medical providers involved in primary, specialty, emergent and acute care will be involved in caring for this population. Training that combined the perspectives and skills of families, health, and behavioral/mental health providers effectively improved knowledge and comfort of medical providers and helped arm them with strategies to implement in their respective medical homes.

Poster Session
177 - Social Cognition and Social Behavior
11:30 AM - 1:30 PM - Room: 710

321 **177.321** Real-World Joint Action and the Autism Spectrum: Separating Social Coordination from Motor Clumsiness

D. A. Trevisan[1,2], *J. T. Enns*[3], *E. Birmingham*[2] *and G. Iarocci*[4], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (3)Psychology, University of British Columbia, Vancouver, BC, Canada, (4)Simon Fraser University, Burnaby, BC, Canada*

Background:

"Joint action"—the ability to coordinate actions with others—is critical for achieving individual and interpersonal goals (Sebanz, 2006), and for our collective success as a species (Tomasello, 2009). Joint actions require accurate and rapid inferences about others' thoughts, intentions, and feelings (Pesquita, Whitwell, & Enns, 2017); skills that are thought to be impaired in ASD (Baron-Cohen, 2005). To date, research has not investigated joint action abilities in ASD during real-world social interactions.

Objectives:

1) To determine if there are joint action differences in children with ASD relative to typically developing (TD) children.

2) To determine if joint action differences in ASD are due to motor clumsiness or differences in cooperation abilities.

3) To determine how joint action differences in ASD are manifested with respect to correlates with behavioral and clinical measures.

Methods:

Participants were children with ASD (n = 26) and TD children (n = 31), 6-12 years old, matched on age and Full-scale IQ (ASD mean = 102.64, TD mean = 109.50). Parents completed continuous measures of ASD traits, alexithymia, and social competence (Table 1).

Participants moved tables through an S-Shaped maze of stationary tables (obstacles) in three different conditions: "Child-Only" (child moved table by him/herself), "Child-Child" (two children moved table together), and "Child-Adult" (child moved table with adult researcher).

Joint action was measured using an iPhone attached to each table installed with a customized App that quantified table movement in three dimensions (greater table movement indicated less coordination).

The table moves were video-recorded so that we could subsequently code behavioral indices of interpersonal synchrony—operationalized as the percentage of time participants stepped synchronously versus asynchronously.

Results:

Children with ASD exhibited less table movement than TD children in the child-only condition, but significantly more table movement than TD children in the child-child condition (all *p*s < .05). This pattern suggests the TD children benefitted more from the aid of a peer than the ASD children (we termed difference scores between child-only and child-child, "cooperation benefit") (Figure 1).

The calculated cooperation benefit was associated with higher verbal IQ (r = .402), higher social competence (r = .290), fewer autistic traits (r = -.302) and less alexithymia (r = -.230) across groups.

Children with ASD spent a significantly lower percentage of time stepping synchronously with their peer during the child-child condition, $t(50.35) = 2.894$, $p = .006$, but this ASD disadvantage was not evident when moving the table with an adult researcher in the child-researcher condition, $t(48) = 0.47$, $p = .934$.

Conclusions:

Children with ASD were less likely to step synchronously with their peer when moving tables collaboratively, and they benefited less than TD

children from the aid of a peer in completing the table-moving tasks. This lower "cooperation benefit" was associated with lower intelligence and social skills and higher alexithymia and autistic traits. The data suggest that joint action is a highly adaptive social process that may be impaired in ASD and not simply explained by motor clumsiness.

322 **177.322** Self-Report of "Camouflaging" Behaviors in Women Is Related to Autism Symptoms and Mental Health but Not Executive Functioning

J. S. Beck[1], *R. A. Lundwall*[2], *T. P. Gabrielsen*[3], *J. Cox*[4], *A. M. Dixon*[1], *M. Ekins*[1], *M. Farmer*[1], *T. DeMordaunt*[1], *L. Peacock*[1], *K. Christensen*[1], *S. Kamhout*[1], *L. Ekins*[1] *and M. South*[2], *(1)Psychology, Brigham Young University, Provo, UT, (2)Psychology & Neuroscience, Brigham Young University, Provo, UT, (3)Counseling & Special Education, Brigham Young University, Provo, UT, (4)Counseling and Career Center, Brigham Young University, Provo, UT*

Background: Autistic women may "camouflage" their differences to appear more typical during social interactions and formal assessments such as the *ADOS-2*. Camouflaging may cause some to be overlooked for diagnosis of autism or misdiagnosed, delaying access to appropriate interventions. To improve diagnostic accuracy, others (e.g., Lai et al., 2016) have attempted to quantify camouflaging and explore clinical correlates and potential mechanisms, such as executive functioning (EF) skills which allow the individual to inhibit autistic tendencies and switch to typical behaviors. A new self-report measure of camouflaging, the Camouflaging Autistic Traits Questionnaire (*CAT-Q*; Hull et al., 2018), was only recently published.

Objectives: We sought to explore the camouflaging phenomenon in the diagnostic "gray zone," where camouflaging can mean the difference between receiving a diagnosis of ASD and not. Accordingly, we investigated a sample that included high-functioning women with ASD as well as undiagnosed (potentially camouflaged) women with the broader autism phenotype. To examine the clinical significance and potential mechanisms of camouflaging, we assessed and explored associations between camouflaging and autism symptoms, indicators of mental health, and EF (inhibition and switching).

Methods: Our sample includes women without intellectual impairment (*N*=51; age *M*=24 years; IQ *M*=114; 15 had a previous autism diagnosis) who reported impairing symptoms associated with ASD per elevated scores on the *BAPQ* (total score>3). Participants were recruited through local clinics, a university counseling center, and social media. We administered measures through an online survey platform and in-person visits. Measures included the *CAT-Q*, *BAPQ, ADOS-2*, *WASI-II* (IQ), *DASS-21* (psychological distress), *TSCS-2* (self-concept), *Suicidal Behaviors Questionnaire*, and *D-KEFS Trail-Making* and *Color-Word Interference* (EF). Before analyses, outliers were Winsorized to 2**SD* above/below the mean. Pearson and Spearman (non-normal variables) correlation coefficients were calculated.

Results: A majority of participants (53%; *n*=27), including a majority of participants with a previous ASD diagnosis (53%; *n*=8), had *CAT-Q* total scores higher than the average score of the ASD group in the *CAT-Q* validation sample (our sample: *M*=4.72*; SD*=0.83; ASD validation sample: *M*=4.79*; SD*=0.99*)*. Similar to findings in the validation sample, our sample showed significant associations between *CAT-Q* total scores and *BAPQ* total scores (*r*=0.28, *p*<0.05) and indicators of mental health (*DASS-21*: *r*=0.27, *p*=0.05; *TSCS-2*: *r*=-0.39, *p*<0.01). *CAT-Q* total scores were *not* associated with suicidal behavior (ρ=0.09, *p*=0.52), EF (*Trails* Condition 4: ρ=-0.1, *p*=0.47; *Color-Word* Condition 4: ρ=-0.15, *p*=0.31), or IQ (*r*=-0.03, *p*=0.81).

Conclusions: Our findings provide support for the validity of the *CAT-Q* and reinforce the clinical relevance of the camouflaging construct. The lack of association between self-reported camouflaging and suicidal behaviors speaks to the complexity of factors influencing suicidality. The lack of hypothesized association between camouflaging and EF leaves open the question of which cognitive abilities allow some individuals to camouflage while others seem unable to do so. Future directions include investigating alternate potential mechanisms of camouflaging behavior, as well as exploring the temporal relationship between camouflaging and psychological distress since distress may motivate and/or result from camouflaging.

323 **177.323** Sex Differences in Social-Communication Function in Children with Autism Spectrum Disorder and Attention-Deficit Hyperactivity Disorder: Data from the Pond Network

T. Mahendiran[1], *A. Dupuis*[2], *J. A. Brian*[3], *X. Liu*[4], *E. Kelley*[5], *S. Georgiades*[6], *R. Nicolson*[7], *J. Crosbie*[8], *R. Schachar*[9] *and E. Anagnostou*[3], *(1)Institute of Medical Science, University of Toronto, Toronto, ON, Canada, (2)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Psychiatry, Queen's University, Kingston, ON, Canada, (5)Queen's University, Kingston, ON, Canada, (6)McMaster University, Hamilton, ON, Canada, (7)University of Western Ontario, London, ON, Canada, (8)Psychology, The Hospital for Sick Children, Toronto, ON, Canada, (9)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada*

Background: There is a strong male prevalence in ASD and ADHD. Even though social-communicative deficits are observed in both ASD and ADHD, to date research examining sex differences in social and communication function in these disorders remains limited and findings are mixed.

Objectives: This study examined potential sex differences in social and communication function in ASD and ADHD.

Methods: 115 youth with ASD, 172 youth with ADHD and 63 typically developing controls (age range 8-12 years, 75% males) were recruited from the Province of Ontario Neurodevelopmental Disorder (POND) Network. Social and communication function were assessed using the communication, leisure and social skill areas of the Adaptive Behaviour Assessment Scale-Second Edition (ABAS-II). To test for sex differences, a logistic regression was performed on the proportion of positive items for each skill area (i.e., communication, leisure and social), controlling for age and sex.

Results: Significant sex by age interactions were seen within ASD on the communication (p=0.005), leisure (p=0.003) and social skill areas (p<0.0001). In all three areas, lower scores were found in females compared to males at the age of 12, despite females performing better than males at the age of 8. There were significant sex by age interactions in the social (p=0.02) and leisure (p= 0.0005) domains between those with ASD and typically developing controls, with typically developing females showing better scores at older ages. Sex by age interactions were significant between ASD and ADHD on the social (p=0.009) and leisure domains (p<0.0001), as females with ADHD consistently scored higher on social skills than males across all ages, unlike those with ASD. Sex differences across age in the social domains for ADHD were similar to those in the typically developing group.

Conclusions: Sex differences in social and communication domains were observed between ASD and ADHD, and typically developing controls, with females with ASD performing worse than males at older ages, despite earlier advantages, potentially suggesting a female –specific phenotype in ASD. This has implications on development of treatments plans that target social function in females with ASD. Furthermore, these findings

reinforce the need to take a developmental/longitudinal approach to understanding sex differences.

324 **177.324** Sex Differences in Toy Preference in Children with Autism Spectrum Disorder and Typical Development

***L. W. Chan**, M. R. Altschuler, M. L. McNair, J. Wolf, E. Jarzabek, A. Naples, T. Winkelman and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background:
The social camouflage theory posits that girls with ASD more commonly and successfully camouflage their symptoms compared to boys with ASD (Lai et al., 2017). One method of camouflage for girls with ASD may include inhibiting self-soothing behaviors and outward responses to sensory overstimulation, with the goal of making their condition less obvious (Hull et al., 2017). Girls with ASD may also play with more female-typical toys compared to boys with ASD to more closely align with the social profile of typically developing (TD) girls (Harrop et al., 2017). Examining sex differences in toy preference and behavior during play may clarify how sex influences sensory behavior and engagement with toys. Moreover, exploring how ASD symptoms relate to toy preference may reveal whether behaviors during play are associated with individual differences in symptom severity, providing insight into clinically relevant sex differences and phenotypic heterogeneity in ASD.

Objectives:

To investigate sex differences in toy preference during play in TD children and children ASD and explore whether symptom severity predicts toy preference during play.

Methods:

Videos of the Autism Diagnostic Observation Schedule (ADOS-2), Module 3 were coded for toy play (the amount of time spent touching a toy) using ELAN software. Videos of children with ASD (n=17; 7 girls; mean age=12.7 years) were coded. Based on Harrop et al. (2017), toys were separated into categories (Vehicles, Figurines, Tools/Weapons, Domestic, Miscellaneous). Independent samples t-tests were conducted to determine sex differences for time spent playing with each category. Toys were categorized as either social (e.g., dinosaur, action figures) or non-social (e.g., wrench). Correlations between ADOS-2 Calibrated Severity Score (CSS) and play time with social and non-social toys, as well as total play time, were calculated. Behavioral coding is ongoing in a sample of available recordings from 60 TD children and 60 children with ASD.

Results:

Girls with ASD played with domestic toys more than boys with ASD (t(15)=2.44, p=.03). There were no categories for which boys showed more play time than girls. Across both sexes, higher CSS was associated with more play with non-social toys (r=.551, p=.013).

Conclusions:

Preliminary results align with Harrop et al. (2017) and indicate that girls with ASD play with domestic toys more than their male counterparts. In contrast, boys with ASD did not play with any category more than their female counterparts, suggesting that increased gender-stereotyped play may be specific to girls with ASD, consistent with the "camouflaging" account of gender roles and toy play. However, increased overall symptom severity was associated with less play with social toys and more play with non-social toys, suggesting that children with ASD, regardless of gender, may display reduced interest in social toys during play.

325 **177.325** Social Camouflaging in Adolescence: Are There Differences across Sex?

***C. Jorgenson**[1], S. M. Kanne[2] and T. Lewis[3], (1)University of Missouri - Columbia, Columbia, MO, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (3)Special Education, University of Missouri, Columbia, MO*

Background: Social camouflaging is hypothesized to be used by individuals on the autism spectrum as means of masking or compensating for their autistic traits (Hull et al., 2017). Results from existing research suggest that autistic females may be more likely to engage in social camouflaging, and that it may have a negative impact on their mental health and well-being. However, much of this research is qualitative and few quantitative studies have sought to examine these hypotheses. In addition, few studies have included analysis of camouflaging in neurotypical (NT) populations.
Objectives: The aim of this pilot study is to compare levels of camouflaging and internalizing symptomology in autistic and NT adolescent males and females. The following research questions were addressed: Do autistic and NT males and females report different levels of camouflaging? Do autistic and NT males and females report different reasons for and consequences of camouflaging? Do autistic and NT males and females report different levels of internalizing symptoms?

Methods: 84 adolescents ages 13-18 years completed an online survey including the Camouflaging Autistic Traits Questionnaire (CAT-Q; Hull et al., 2018), Subthreshold Autism Traits Questionnaire (SAT-Q; Kanne et al., 2012), and Depression, Anxiety, and Stress Scales-21 (DASS-21; Lovibond & Lovibond, 1995). Twenty-five participants were on the autism spectrum (14 females and 11 males) and 59 were NT (34 females and 25 males). In addition, 9 adolescents on the autism spectrum and 8 NT adolescents completed follow-up interviews. The interviews were conducted to obtain richer information about participant motivations for and consequences of camouflaging.

Results: Autistic females report the highest levels of camouflaging (M=87.23, SD=21.58), followed by NT females (M=76.75, SD=21.23). Autistic males (M=70.91, SD=20.99l) and NT males (M=70.91, SD=22.95) report the same level of camouflaging. Trends have also emerged in the subscales of the CAT-Q. Autistic females report the highest levels of anxiety, while autistic males report the highest levels of depression and stress. Trends are also emerging in the interview data, with most participants describing camouflaging to some degree, but females on the autism spectrum reporting it to be more necessary, difficult, and exhausting than other participants.

Conclusions: The preliminary results of this study support and add to the existing literature. Females on the autism spectrum report the highest levels of camouflaging and the most detrimental effects. While camouflaging may be beneficial for all groups in some social situations, the negative effects these behaviors can have on well-being suggest that they may also be problematic. Further analyses of this data will (a) examine whether scores on the CAT-Q are associated with scores on the DASS-21 and (b) compare participant groups on subscales of the CAT-Q (compensation, masking, and assimilation).

326 **177.326** Social Camouflaging in the Presentation of Suspected Autism Spectrum Disorder in Toddler Girls

E. G. Ronkin[1], *E. B. Tone*[1], *C. Hall*[2] *and L. J. Dilly*[3], *(1)Georgia State University, Atlanta, GA, (2)Emory University, Marcus Autism Center, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA*

Background: Autism spectrum disorder (ASD) is more frequently diagnosed in males than in females, with ratios varying from 2:1 to 12:1 (e.g., Frazier & Harden, 2016; Whiteley et al., 2010). This imbalance could stem, in part, from a heightened tendency for girls with ASD to engage in "social camouflaging," or compensatory behaviors that mask their symptoms relative to their male counterparts (Kreiser & White, 2013), including staying close to peers, jointly engaging with peers, and weaving in and out of peer groups (Dean, Harwood, & Kasari, 2017). Girls with ASD may also engage more than their male peers in social initiation behaviors that conceal complex difficulties forming and maintaining relationships, such as making eye contact, appropriately production of facial expressions, initiating social interactions, and making requests (Harrop et al., 2015; Oien et al., 2016; Spies et al., 2011). Limited research, however, has compared these discrete social communication behaviors between boys and girls using validated ASD assessment measures.
Objectives: The current study investigated sex differences in social communication behaviors assessed by the ADOS-2 Toddler Module. We hypothesized that toddler girls referred for an ASD evaluation would exhibit better and more frequent social initiation behaviors (eye contact, facial expression, social overtures, and requesting) than would their male counterparts.

Methods: We tested hypotheses using data from a diverse sample of toddlers (n=214; 26% female, Mean age=25 months, 47% White) referred for an ASD evaluation at an outpatient autism center where research-reliable clinicians administered the ADOS-2 Toddler Module (Lord et al., 2012).

Results: As predicted, girls initiated significantly more social overtures with parents than did boys in both univariate ($t = -2.66$; $p < .01$) and multivariate analyses ($F = 7.09$, $p < .01$). However, no significant sex differences were evident for eye contact, facial expressions, or requesting.

Conclusions: Findings suggest that among the ADOS-2 Toddler Module social communication items, it may primarily be those measuring the tendency to extend social overtures that differentiate girls referred for an ASD evaluation from boys. Other behaviors that prior research has shown to differ between girls and boys with ASD (eye contact, facial expressions, requesting) did not show sex differences in the present study. Girls with ASD often engage in "social camouflaging" behaviors, which may reflect gendered socialization patterns (Dean et al., 2017). For instance, girls with ASD more often situate themselves near peer groups and report wanting to be socially involved with others than do boys (Attwood, 2006). However, once girls initiate social interactions, they may have difficulties sustaining them, much like their male peers (Cridland et al., 2014). These findings raise the possibility that the social overture item may not be an optimal indicator of ASD in toddler girls. Thus, identifying specific items, such as social overtures toward parents/caregivers, where girls and boys differ, may suggest areas of sex-specific strengths or weaknesses that could facilitate early diagnosis.

327 **177.327** Social Judgements and Reactions to Social Rejection in Young Adults with Autism

E. Gurbuz[1], *M. Hanley*[2], *M. South*[3] *and D. M. Riby*[4], *(1)Psychology, Durham University, Durham, United Kingdom, (2)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (3)Psychology & Neuroscience, Brigham Young University, Provo, UT, (4)Department of Psychology, Durham University, Durham, United Kingdom*

Background: Autistic individuals are at substantial risk for peer rejection, alongside more frequent experiences of loneliness, isolation and bullying. Such experiences likely contribute to heightened rates of mental ill-health, including increased rates of anxiety, depression and suicide (Jackson et al., 2017). Research has shown that autistic individuals are less accurate in predicting how others would perceive their personality, and less accurate at judging others' faces in terms of social approach characteristics (e.g. trustworthiness and kindness). However, it is less known how autistic individuals perceive and respond to social rejection from others and this may be crucial for shaping social experiences.
Objectives: The primary objective of the current study was to provide the first insights into combined behavioural and psychophysiological markers of social rejection in autistic adults. A secondary objective was to relate these markers to self-reports of depression, anxiety, and stress.

Methods: 20 autistic university students (11 males, mean age =23.58) and 40 neurotypical students (21 males, mean age =22.83) participated. Participants were asked to provide a 'profile picture' to be shown to other students. In the experiment, participants were shown photos of adult faces and told these were students from their university. For the social judgement task (SJT) participants were asked to evaluate whether the students in the pictures would have 'liked' the participant from their profile picture, then subsequently given feedback on whether their evaluations were correct or incorrect. In reality, the feedback was randomly created by the computer programme such that there were 50% 'YES' and 50% 'NO' (rejection) trials. In the age judgement task (AJT), participants estimated the age of the person in the picture and were given feedback on their evaluations. Behavioural responses and psychophysiological cardiac reactivity (inter-beat intervals; IBIs) were measured. Participants completed the Autism Quotient (AQ; Baron-Cohen et al. 2001), Liebowitz Social Anxiety Scale (LSAS; Liebowitz, 1987) and Depression Anxiety and Stress Scale (DASS-21; Lovibond & Lovibond 1995).

Results: Between-group behavioural and psychophysiological analyses were conducted. Autistic participants predicted they would be rejected on 56% of trials compared to 48% for the neurotypical group. Importantly, the psychophysiological results showed a significant difference between groups. The neurotypical participants had longer inter-beat intervals following social rejection trials indicating transient cardiac slowing. However, the autistic participants did not show cardiac slowing to the same trials (see Figure 1 panels A and B). These results were not due to generalised negative feedback effects, as the pattern was absent from the age judgement task. Finally, there were significant correlations between negative self-bias and AQ (r=.335, p=.009), LSAS (r=.505, p<.001), and DASS-21 scores (r=.296, p=.02).

Conclusions: Autistic adult participants showed atypical cardiac responsivity to social rejection within a social judgement task. It may be hypothesized that experience of social rejection in autistic adults has a down-regulation effect on psychophysiological responses as a potential compensatory mechanism.

328 **177.328** Social Monitoring of Conversation Partners in Young Children with ASD

T. Tsang, *E. Yhang, C. D. Gershman, K. Joseph, H. Neiderman, C. Nutor, N. Powell, K. Villarreal, A. Vernetti, S. Fontenelle, K. K. Powell, S. Macari and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Attenuated attention to ostensive social bids (e.g., gaze cues, speech) appears to be a prodromal and early syndromal feature of ASD (Charwarska et al., 2012; Shic et al., 2014). These early differences in social monitoring may compromise the uptake of foundational social

communicative inputs and contribute to difficulties in language and social competency. Recent work suggests that simplified humanoid figures not only facilitates attention to faces (Tsang et al., 2018), but may also support learning when used in ASD interventions (Scassellati et al., 2018). However, it is unclear whether simplified humanoid figures (e.g., puppets) are regarded as equivalent social agents to people, and whether children with ASD are receptive to their social communicative bids. This will critically inform the application of simplified social figures as tools to increase social learning opportunities in ASD.

Objectives: (1) Examine how children with ASD monitor a conversation between a puppet and person, and (2) its association with social communicative competence. Simpler humanoid figures (e.g., puppets) may facilitate attention to relevant social information for children with ASD, relative to their typically developing (TD) and developmentally delayed (DD) peers, which may provide supported social learning opportunities.

Methods: 81 participants (ASD: N=29, Mean=46.25(SD=14.76) months; DD: N=25, Mean=51.29(SD=17.39) months; TD: N=27, Mean=39.83(SD=10.94) months) were eye-tracked while they freely viewed a video depicting a puppet and person engaged in an animated conversation (Figure 1). Participants were characterized using the ADOS-2 and a cognitive test (e.g., Mullen or DAS). Eye-tracking data were analyzed under two conditions: 1) Puppet-Speaking/Person-Listening and 2) Person-Speaking/Puppet-Listening. For each condition, we measured overall percent looking at the scene (%Valid), percent of valid looking directed at faces (%Face_Speaker, %Face_Listener), and a composite ratio of relative attention to the speaker versus listener within the dyad (i.e., time spent looking at the speaker divided by looking to either speaker or listener). Attention to faces was analyzed using a 3 (Diagnosis) x 2 (Condition) x 2 (Social Agent: puppet vs. person) repeated-measure ANCOVA, covarying for age. Associations between the composite ratio metric and clinical features were evaluated.

Results: The ASD group had lower %Valid in Puppet-Speaking/Person-Listening (F(2,80)=3.984,p=.022) and Person-Speaking/Puppet-Listening conditions (F(2,80)=7.033,p=.002) than TD and DD groups. There was a significant 3-way interaction (F(2,77)=5.34, p<.001, partial eta2=.12)—children with ASD had lower %Face_Speaker-Person, but not %Face_Listener-Puppet, in the Person-Speaking condition; all diagnostic groups showed similar patterns of %Face_Speaker-Puppet and %Face_Listener-Person in the Puppet-Speaking condition (Figure 2). In the ASD group, a higher puppet-speaker to person-listener ratio was moderately associated with higher ADOS scores (r=.47,p=.06). Conversely, a higher person-speaker to puppet-listener ratio was associated with lower symptom severity (r=-.41,p=.03), and higher verbal (r=.46,p=.01) and nonverbal (r=.59,p=.001) cognitive skills.

Conclusions: Overall, children attend to the speaker in a conversational dyad. While children with ASD attended less to the social scene than their TD and DD peers, the presence of the puppet effectively engaged children with ASD to socially monitor conversational partners. Perceptually salient, humanoid forms may serve as alternative routes for social learning especially in lower functioning and cognitively/verbally challenged children with ASD.

329 **177.329** Social Motivation By Self- and Parent-Report: Reporter Correspondence and Social Correlates

E. Neuhaus[1]*, R. Bernier*[2] *and S. J. Webb*[2]*, (1)Seattle Children's Hospital, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: According to several theoretical models, deficits in social motivation underlie the core social deficits observed in autism spectrum disorder (ASD), supported by evidence from behavioral, neuroimaging, and physiological studies. However, social motivation is rarely investigated as a multi-dimensional construct that can vary across social contexts. Also absent from most research of social motivation are subjective reports from individuals with ASD, despite the unique insight they may provide.

Objectives: To investigate social motivation in children with and without ASD, with attention to social context and reporter. Specifically, we examine (1) concordance between self- and parent-report of social motivation; (2) group differences in social motivation by reporter and social context; and (3) associations between social motivation and other social outcomes by reporter and social context.

Methods: A total of 56 verbally fluent children (20 ASD, 36 non-ASD) from 8 to 13 years of age (mean = 10.2 years, *SD*=1.4, range=8.0-12.9) and their parents completed the self-report and parent-report versions of the Dimensions of Mastery Questionnaire (DMQ), respectively. The DMQ yielded two indices of social motivation – Social Persistence with Adults, and Social Persistence with Children – which reflect a child's typical effort toward and enjoyment of social interactions and relationships with adults and same-age peers, respectively. Social skills were assessed via parent-report using the Vineland Adaptive Behavior Scales, 2nd Edition (Vineland-2) Socialization standard score and the Child Behavior Checklist (CBCL) Social Problems *T*-score. All children with ASD met clinical cut-offs on ADOS-2, ADI-R, and DSM-5 criteria.

Results: Concordance between children's self-report and that of their parents varied by social context. WIthin each group, motivation with adults was significantly correlated across reporters (ASD: *r*=.53, *p*=.03; non-ASD: *r*=.55, *p*=.001) but motivation with peers was not (ASD: *r*=.03, *p*=.9; non-ASD: *r*=.32, *p*=.06). Group comparisons indicated that parents rated children with ASD as lower than non-ASD children in motivation with both adults (*t*=2.77, *p*=.008) and with peers (*t*=4.33, *p*<.001), whereas children's self-report indicated lower motivation in the ASD group with peers (*t*=3.07, *p*=.003) but not adults (*t*=1.5, *p*=.14). Finally, within the ASD group, self-reported motivation with peers was negatively correlated with Social Problems on the CBCL (*r*=-.68, *p*=.002), and motivation with peers (*r*=.49, *p*=.04) and adults (*r*=.54, *p*=.02) was positively correlated with social skills on the Vineland-2, whereas parent-reported social motivation was not significantly correlated with either measure (*r*s<.025, *p*s>.29). Within the non-ASD group, neither children's self-report ratings nor parents' ratings of social motivation were significantly correlated with social skills on the CBCL or Vineland-2, likely due to restricted range on these measures for children without ASD.

Conclusions: Although children with ASD do report decreased social motivation relative to peers, social motivation may not be a unitary construct and may instead vary across social contexts and reporters. While parents' and children's reports provide some overlapping information regarding social motivation, children with ASD provide an under-appreciated perspective that carries unique statistical value in understanding their social skills and experiences. Results underscore the need for multi-context and multi-reporter assessment of complex processes such as social motivation.

330 **177.330** The Influence of Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder Symptom Severity on the Facial Emotion Recognition Skills of Adolescents

R. A. Vogel*, K. M. Hauschild and M. D. Lerner, Psychology, Stony Brook University, Stony Brook, NY*

Background: Autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD) have a high degree of comorbidity but differential etiology (Leitner, 2014). Previous studies reported deficits in facial emotion recognition (FER) associated with poorer social functioning (Høyland et al., 2017; Kats-Gold, 2007) in both ASD (Lozier et al., 2014) and ADHD (Da Fonseca, 2009) populations. When examined categorically, diagnoses of ASD and ADHD have been associated with differential deficits in FER (Buitelaar et al., 1999; Berrgren et al., 2016); however, despite the disorders' frequent co-occurrence, no work has examined the relative influence of ADHD and ASD symptom severity on FER within the context of ASD diagnosis (Webb, Neuhaus, & Faja, 2017; Miller et al., 2011).

Objectives: To determine the unique influence of ASD and ADHD symptom severity on FER abilities in adolescents with and without ASD.

Methods: Using a standardized assessment of FER (DANVA-2; Nowicki, 2004), data were collected from 86 adolescents with and without ASD (Table 1). ADOS-2 (Lord et al., 2012) Comparison Score was used to measure ASD symptom severity. Parents of participants reported adolescent's ADHD (Combined Type) symptom severity via the CASI-5 (Gadow and Sprafkin, 2013). A One-Way ANOVA determined if FER and symptom severity differed between diagnostic groups. Pearson correlations assessed relationships between ASD and ADHD symptom severity and FER in each group.

Results: FER performance did not differ as a function of ASD diagnosis ($F(1,84) = 1.48$, $p = .23$). For the ASD group, ASD symptom severity was associated with greater FER errors ($r(38) = .45$, $p < .01$; Figure 1), with the relationship driven primarily by errors for happy ($r(38) = .40$, $p = .01$) and fearful facial expressions ($r(38) = .52$, $p < .01$). For non-ASD participants, ADHD symptom severity corresponded with greater FER errors ($r(44) = .38$, $p < .01$; Figure 1), with the relationship driven primarily by errors for high-intensity ($r(44) = .50$, $p < .001$) and sad expressions ($r(44) = .34$, $p = .02$).

Conclusions: These results support previous findings of disorder-specific FER deficits associated with ASD and ADHD. For individuals with ASD, FER errors were associated with ASD, but not ADHD symptom severity. FER errors for happy (Berrgren et al., 2016) and fearful (Ashwin et al., 2006) expressions were particularly associated with more severe ASD symptom presentation. Conversely, for non-ASD participants, FER errors were associated with ADHD symptom severity but not ASD symptom severity. This finding is particularly interesting given that the ASD group demonstrated greater overall levels of ADHD symptom severity relative to the non-ASD group. Additionally, in the non-ASD group, participants with greater ADHD symptom severity made more FER errors for high-intensity emotions, indicating greater relative impairments on less difficult FER trials. Overall, these findings suggest that once ASD symptoms reach a threshold of clinical significance for diagnosis, they may be more influential in contributing to deficits in FER than ADHD symptoms for adolescents.

331 **177.331** Spontaneous Mentalizing in Children with and without ASD

R. El Kaddouri[1], *M. Brass*[2] *and J. R. Wiersema*[3], *(1)Experimental Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Experimental Psychology, Ghent University, Ghent, Belgium, (3)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background:

A deficit in Theory of Mind (ToM) or mentalizing has been argued to play a causal role in the development of social difficulties in individuals with autism spectrum disorder (ASD). However, findings are inconclusive as many individuals with ASD pass standard mentalizing tasks, in which they are required to explicitly reason about the beliefs of another agent. It has been argued that they succeed by using compensatory strategies, but still encounter difficulties in daily life because individuals with ASD suffer from a specific impairment in spontaneous mentalizing. There is initial support for this hypothesis, however, studies are scarce and are mainly based on adult research.

Objectives:

Our main objective was to investigate spontaneous mentalizing in children with ASD. We expected that children with ASD would show less spontaneous mentalizing compared to neurotypical children. Additionally, we aimed to investigate if mentalizing abilities are related to ASD symptom severity.

Methods:

The current study is still ongoing and includes at this point 44 children between 7 and 13 years old, of which 23 children with a formal ASD diagnosis and 21 neurotypical children. We aim to eventually include 35 children in each group. Participants carried out a spontaneous mentalizing paradigm based on the ball detection task developed by Kovàcs, Téglás and Endress (2010). This is a false belief task that consists out of two phases: the belief formation phase and the outcome phase. In the first phase, an agent and the participant form a false or true belief about the location of a ball. In the outcome phase they have to detect if the ball is present or not. The ball was present in 50% of the trials, independent of what happened during the clip. This paradigm allows us to investigate how reaction times to the ball are affected by their own belief and by the belief of an agent, hence giving us an implicit measure of mentalizing. ASD symptomatology was measured by two questionnaires namely the Social Responsiveness Scale 2 (SRS-2) and the Social Communication Questionnaire (SCQ) as well as by the ADOS-2.

Results:

Ball detection time of neurotypical children is influenced by the belief of the agent, being faster when the agent believed the ball was behind the occluder, indicating that they spontaneously take into account the belief of the agent. Conform our hypothesis, this effect was absent in children with ASD, suggesting impaired spontaneous mentalizing. This effect was negatively correlated with ASD symptoms. Children with more severe ASD symptomatology showed stronger impairment in spontaneous mentalizing.

Conclusions:

Our findings indicate that neurotypical children do spontaneously take into account the belief of another agent, while children with ASD show a lack of spontaneous mentalizing. This impairment was associated with reported social difficulties in daily life. This deficit in spontaneous mentalizing may explain their persistent social difficulties, in which often fast spontaneous mentalizing is required. As studies are scarce, replication is warranted, also applying other implicit mentalizing tasks.

332 **177.332** The Association of Early Theory of Mind to Two-Year-Later Pretend Play Performance in Children with Autism Spectrum Disorder

M. R. Liu[1], *H. M. Chiu*[2], *C. H. Lin*[3], *C. H. Tsai*[4], *H. J. Li*[4] *and K. L. Chen*[5], *(1)Department of Occupational Therapy, National Cheng Kung University, Tainan, Taiwan, (2)Department of Rehabilitation, Chung Shan Medical University Hospital, Taichung, Taiwan, (3)Department of Psychiatry, Chi Mei Medical Center, Tainan, Taiwan, (4)Department of Child and Adolescent Psychiatry, Kaohsiung Municipal Kai-Syuan Psychiatric Hospital, Kaohsiung, Taiwan,*

(5)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: Theory of mind (ToM) deficit and poor pretend play are two characteristics of children with autism spectrum disorder (ASD). ToM is a social cognitive ability to infer the mental states of self and others and thereby to make appropriate replies. Via ToM, children can impute others' beliefs to usual presentations and then can generate new ways to pretend. Therefore, children's ToM ability may benefit the generation of pretend play. However, the association of early ToM development to later pretend play performance has not been examined.
Objectives: The main purpose of this study was to clarify how early ToM ability is related to two-year-later pretend play in children with ASD.

Methods: A total of 83 children with ASD aged 5-12 years were included for two evaluations. In the first evaluation, the Theory of Mind Task Battery (ToMTB), Verbal Comprehension Index of the Weschler Intelligence Scale for Children, Fourth Edition, (VCI, WISC-IV), and Childhood Autism Rating Scale (CARS) were respectively administered to assess ToM, verbal ability, and symptom severity. Two years later, in the second evaluation, the Child-Initiated Pretend Play Assessment (ChiPPA) was administered to evaluate children's pretend play in two sessions: conventional imaginative play and symbolic play. In these two sessions, the percentage of elaborate pretend play actions (PEPA), number of object substitutions (NOS), and number of imitated actions (NIA) were respectively scored as measures of the quality, quantity, and creativity of pretend play. Pearson's product-moment correlation coefficients and linear regression models were used for data analysis.

Results: The children's mean age was 71.98 months (SD = 19.82) at the first evaluation. The earlier ToMTB scores (r=.256, p=.019; r=.217, p=.049; r=-.220, p=.046) had positive associations with the PEPA-conventional imaginative play and total scores, as well as negative association with the NIA-symbolic play scores The earlier VCI (r=.240, p=.029; r=.275, p=.012; r=.300, p=.006) had positive associations with the PEPA-conventional imaginative play, symbolic play and total scores. The earlier CARS scores had positive associations (r=.264, p=.016) with only the NOS-conventional imaginative play scores. The results of the regression models showed that in addition to the earlier VCI and CARS scores, the earlier ToMTB scores could not additionally predict the PEPA-symbolic play scores. Other models were not significant.

Conclusions: Children with ASD who have better early ToM ability are likely to have better quality and creativity of pretend play. However, despite considering early VCI and symptom severity, the early ToM ability could not further predict pretend play. Verbal ability seemed to be the more important predictor of pretend play in children with ASD. ToM ability is known to have close developmental coexistence with verbal ability. Therefore, ToM ability may be associated with pretend play via the mediation of verbal ability in children with ASD. The association of early ToM, verbal ability, and symptom severity to pretend play in children with ASD will require further research with larger sample sizes to provide more solid evidence.

333 **177.333** The Discriminant Power of the Combination of Oculometric and Pupillometric Parameters during the Exploration of Objects and Faces between Autism Spectrum Disorders and Typical Development

***C. Wardak**[1], N. Hernandez[1], A. Saby[2], J. Malvy[1,2], M. Guimard-Brunault[2], J. Martineau[1], F. Bonnet-Brilhault[1,2] and Y. Mofid[1], (1)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (2)CHRU Tours, Tours, France*

Background: Autism Spectrum Disorders (ASD) are characterized by impairments in social communication and atypical social interactions. These impairments could be related to an alteration of face and social stimuli processing. Many studies have used eye-tracking in order to identify key parameters specific to ASD visual exploration, particularly of faces and social situations. However, if several parameters have been identified (e.g. time spent on the eyes region during face observation, preference for non-biological over biological movement), none of them allow to distinguish between ASD and Typical Development (TD) subjects with more than 70-80% discrimination power.
Objectives: The aim of this study was to explore how the combination of several eye-tracking parameters could improve the discrimination between ASD and TD children compared to each parameter individually.

Methods: Eye position and pupil diameter were recorded with an eye-tracking system (FaceLAB®) in 87 ASD and 96 typical children (3-12 years old) during a passive observation paradigm in which images of objects and faces were presented. These stimuli were interleaved with grey images containing a black cross (baseline). At the beginning of the paradigm, black and white images were also presented in order to elicit a pupillary light reflex.

A total of 18 parameters were extracted from the different conditions (baseline, objects, faces, black/white images) and the two measurements: pupil (diameter, speed) and gaze (total tracking time, time spent on the screen or the stimulus, fixation duration, number of fixations, latency to the first fixation).

A Receiver Operating Curve (ROC) analysis was conducted in order to determine the discrimination power of individual parameters, estimated by the Area Under a Receiver Operating Curve (AUC). We then used a data-mining approach combining all oculometric and pupillometric parameters using a logistic regression model. A ROC analysis was conducted to estimate the discrimination power of the model.

Results: The analysis required to determine the 18 parameters for all the subjects without any missing data. In total, 18 ASD children and 33 TD children were included in the analysis.

Some individual parameters reached a discrimination power between the ASD and TD groups of about 80%, e.g. the time spent on faces for children older than 8 years-old.

The combination of the 18 parameters reached a >95% discrimination power for children under 8 years-old (with a sensitivity and a specificity of >95%). The results stayed really good when the 9 and 10 years-old were also included (AUC 93%, sensitivity 85%, specificity 88%), and lowered to 82% when the 11 and 12 years-old were added.

Conclusions: These results suggest that eye-tracking parameters are very effective to discriminate ASD and TD children when combined, particularly for younger children. Analyses still have to be pursued in order to determine which parameters are crucial to describe the evolution of the exploration strategies with age, both in ASD and TD children. These results will need to be replicated with a new and large group of patients, but are very promising to help the clinical diagnosis and follow the evolution of individual patients.

334 **177.334** The Effect of Autism Knowledge and Diagnostic Labels on Stigma Towards Autism

***D. R. Jones**, K. E. Morrison, K. M. DeBrabander and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

Background: Although neurotypical (NT) adults evaluate peers with autism more favorably when they are made aware of their diagnosis, this pattern does not occur for NTs harboring high stigma about autism (Morrison et al., under review).
Objectives: The current study examines whether stigma-related attitudes in NTs are activated differently depending upon how an autism diagnosis is presented.

Methods: Neurotypical college students (n=266) (mean age = 21.55; SD = 4.61) completed six surveys answering questions in regard to one of eight labels, four referring to autism (Autistic, Autism, Autism Spectrum Disorder, Asperger's), and four comparison labels (Schizophrenia, Schizophrenic, Clinical Disorder, Clinical Diagnosis). The Prejudice Scale (Hori et al., 2011) and the Social Distance Scale (SDS; Gillespie-Lynch et al., 2015) measured the raters' stigma and willingness to interact with individuals with each label. The Attributes and Reactions Scale (AAR; Angermeyer & Matschinger, 2003) evaluated the perceived negative attributes (danger, dependency on others) and emotional reactions (fear, pity, anger) ascribed to different labels. The General Knowledge Questionnaire (Jensen et al., 2016) was used to assess raters' beliefs about the prognosis and level of intelligence of people with each label, while the Autism Awareness Survey (AAS; Gillespie-Lynch et al., 2015) assessed autism knowledge.

Results: For the four autism labels, greater autism knowledge among NTs was associated with less evoked fear (R^2= -.273; p=.001), less perception of danger (R^2= -.401, p< .001), and reduced belief that autism requires dependency on others (R^2= -.288, p=.001). NTs with greater autism knowledge also endorsed a more positive prognosis (R^2 = .401, p<.001) and perceived greater functioning within relationships (R^2=.218, p=.01) for individuals with autism. Autism knowledge also correlated with social distance (R^2=.207, p=.015): NTs with higher autism knowledge were more willing to interact with autistic individuals.

For stigma, levels of social distance and endorsements of fear and pity differed across labels (ps<.01). The schizophrenic label evoked more fear than the autistic, autism, and clinical diagnosis labels (ps<.01), but no label comparisons survived the correction for social distance (*ps*>.052) and pity (*ps*>.09).

NTs provided different intelligence and prognosis ratings across labels (*ps*<.004). The label Asperger's was associated with more intelligence than the schizophrenia, schizophrenic, and generic clinical disorder labels (*ps*<.04), and raters endorsed more positive life outcomes for individuals with autism and Asperger's compared to the generic clinical diagnosis label.

Conclusions: Levels of stigma did not differ across the four autism labels, suggesting that how autism is described does not induce distinct stigma-related attitudes. However, the label Asperger's produced higher ratings of intelligence, and both autism and Asperger's were rated as having better prognoses, suggesting each may be associated with perceptions of higher functioning. Additionally, higher autism knowledge was associated with better perceptions and decreased stigma of autism. Autism also was perceived more favorably than schizophrenia or a general clinical diagnosis. Although autism may therefore be viewed more favorably than some other conditions, results suggest that efforts to increase autism knowledge among NTs may help to further reduce stigma and prejudice.

335 **177.335** Social and Object Attention in Autism Is Modulated By Biological Sex and Gender-Typicality of Objects

D. R. Jones[1], *S. Nowell*[2], *J. Parish-Morris*[3], *N. J. Sasson*[1], *S. Zheng*[4] *and C. Harrop*[5], *(1)University of Texas at Dallas, Richardson, TX, (2)University of North Carolina at Chapel Hill, Carrboro, NC, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Psychiatry, University of California, San Francisco, San Francisco, CA, (5)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Decreased attention to social stimuli is a consistently replicated feature of Autism Spectrum Disorder (ASD). Due to the sex imbalance in ASD diagnoses, previous eye-tracking studies consist largely of males. However, recent literature suggests that females with ASD differ from males, with ASD girls appearing more socially motivated than ASD boys (Sedgewick et al., 2016). Emerging evidence suggests that ASD girls may also differ in social attention, with some attentional patterns similar to TD girls (Harrop et al., 2018a, 2018b). Therefore, a naturalistic eye-tracking paradigm may reveal differences in social attention and motivation in ASD girls.
Objectives: The aim of this current study was to understand the impact and interplay between biological sex and gender on social attention in ASD.

Methods: 79 children (ages 6-10) participated: 46 ASD (21 female); 33 typically developing (TD; 17 female). Subjects completed a dynamic eye-tracking paradigm with 18 silent videos of child actor pairs playing independently (Solo Condition), together (Joint Condition) or in parallel. Pairs played with toys that were either gender-typically *male* (Lego, action hero, science kit) or gender-typically *female* (My Little Pony, Barbie, cooking set). Actor sex was manipulated, so that the effect of gender/sex congruence between toy and actor could be explored. Dependent variables included percent of time attending to faces and hands with toys across conditions.

Results: In the joint play condition, children with ASD spent proportionally less time attending to faces compared to TD children, $F = 2.8$; $p = .05$. In the solo play condition, there was a marginal group*sex effect, where ASD males allocated proportionally less time to faces, $F = 3.7$; $p = .059$. No significant effects were found for overall attention to hands with toys. However, sex differences were found when the gender of the toy was taken into account, with females spending proportionally more time attending to hands with toys when a *female* toy was presented, $F = 4.45$; $p= .02$. Children showed an attentional preference for gender/sex congruent play, with females allocating proportionally more attention to *female* toys matched with a female actor, $F = 5.7$; $p = .02$ and males spending proportionally more time attending to *male* toys matched with a male actor, $F = 3.97$; $p= .05$.

Conclusions: Our data support previous findings of a disjointed attentional profile among ASD females. ASD females attended more to female-oriented stimuli than ASD males, with attention patterns comparable to TD females. This extends previous findings of more female-typical interests among ASD females (Harrop et al., 2018a, Sutherland et al., 2017). Our findings largely replicate previous findings of reduced social attention in ASD. However, when the scene was socially *lean* (children playing alone), ASD females attended to faces to the same degree as both TD males and females. This aligns with previous findings, which suggest that ASD females share features with both TD girls and ASD boys (Harrop et al., 2018b). These findings highlight the importance of considering the gender-typicality of objects when developing stimuli for children with ASD.

336 **177.336** The Interaction of Autism Traits and Psychosis Traits on Mentalizing in a Clinical-Community Sample

L. E. Bradstreet[1,2], *P. I. Paragas*[1], *F. Zhang*[2], *M. E. Calkins*[3], *P. J. Moberg*[3], *B. P. Daly*[2], *M. T. Schultheis*[2] *and D. L. Robins*[1], *(1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)Psychology, Drexel University, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA*

Background: Previous research suggests dimensional traits that characterize autism spectrum disorder (ASD) and psychotic spectrum disorders (PSDs) are useful for understanding variations in social cognition. Notably, in individuals without clinical diagnoses, concurrent high levels of both sets of traits are associated with better performance on social cognitive tasks relative to discordant levels of traits (i.e., high on one set of traits, low on the second set of traits; Abu-Akel et al., 2015). The current study extends previous work on this "normalizing effect" by examining effects of autism traits, psychosis traits, and their interaction on mentalizing in a combined clinical-community sample of individuals with and without ASD.
Objectives: The current study examines 1) main effects of autism traits, 2) main effects of psychosis traits, and 3) interaction effects of autism and psychosis traits on mentalizing accuracy (forced-choice task) and spontaneous mentalizing levels (open-ended task).

Methods: Seventy-six adolescents and adults (M_{age}=22.18 years, *SD*=4.51 years; 19 females) completed the Wechsler Abbreviated Scale of Intelligence, 2nd Edition (WASI-II), Autism Spectrum Quotient (AQ; autism traits), Schizotypal Personality Questionnaire, Factor 1 Cognitive-Perceptual (SPQ-Cognitive; psychosis traits), Social Attribution Task-Multiple Choice (SAT-MC; mentalizing accuracy), and the Dynamic Interactive Shape Clips Task (DISC; mentalizing levels). Thirty-two individuals (eight females) had ASD diagnoses confirmed by record review. We conducted multiple linear regression analyses to evaluate main effects and interaction effects of mean-centered autism traits and psychosis traits on SAT-MC mentalizing accuracy and DISC mentalizing levels with WASI-II Vocabulary scores as a covariate. When data distributions violated assumptions of analytic procedures, we evaluated the significance of results by generating p-values and confidence intervals using bootstrapping based on 5,000 samples. We used the PROCESS macro for SPSS and, specifically, the Johnson-Neyman Technique to probe significant interactions.

Results: Bivariate correlations showed that AQ scores had significant relationships with SPQ-Cognitive ($\rho(76)$=.26, p=.02) and SAT-MC scores ($\rho(76)$=-.26, p=.02). SAT-MC and DISC scores were positively related ($\rho(75)$=.37, p=.001). In the regression models, AQ scores were significantly negatively related to SAT-MC scores, $F(2,73)$=14.67, p<.001, R^2=.29, ΔR^2=.07, β=-.26,p=.01, but not DISC (*ps*>.05). SPQ-Cognitive was not related to SAT-MC or DISC scores (*ps*>.05). The interaction term, AQ x SPQ-Cognitive, was significantly negatively related to SAT-MC scores (R^2=.33, $F(4,71)$=8.65, p<.001, ΔR^2=.04, β=-.20,p=.03) and DISC scores (R^2=.18, $F(4,70)$=3.72, p=.008, ΔR^2=.05,β=-.23,p=.04), such that higher levels of both autism and psychosis traits related to the poorest performance on mentalizing tasks.

Conclusions: We found an enhancing negative effect of autism traits and psychosis traits on mentalizing accuracy and levels in a combined sample of individuals with and without ASD. Specifically, individuals with concurrent high levels of these traits performed *less accurately* on a forced-choice mentalizing task and made the *fewest, least complex* mental state attributions during an open-ended mentalizing task compared to individuals with discordant levels of traits. Our results suggest that relative levels of these traits exert an enhancing negative effect on some forms of social cognition and behavior. The normalizing effect documented in a previous study may not be present for all social cognitive skills or when traits reach clinically significant levels.

337 **177.337** The Relationship between Social Knowledge, Social Behavior, and Peer Victimization in Adolescents with ASD

C. M. Keifer[1], *E. Kang*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: Individuals with autism spectrum disorder (ASD) are at greater risk for peer victimization than typically developing (TD) adolescents (Maïano, Normand, Salvas, Moullec, & Aimé, 2016) and more susceptible to the negative outcomes associated with peer victimization (Adams, Taylor, Duncan, & Bishop, 2016). Social skills deficits are pathognomonic to ASD and have also been linked to increased victimization in non-ASD youth (Ung et al., 2016). Two components of social skills are social knowledge, the ability to explicitly identify appropriate social behavior in context, and social behavior, the performance of socially appropriate actions. However, no study has examined the relative relationship of social knowledge vs. behavior with peer victimization. Clarification of this association could inform interventions to support social development in youth with ASD at risk for peer victimization.
Objectives: Examine the relationship between social behavior, social knowledge, and peer victimization in adolescents with and without ASD. Determine the relative role of social behavior versus social knowledge in predicting victimization.

Methods: Fifty adolescents with ASD (M_{age}=12.69, SD_{age}=1.97; 39 male) and 57 TD adolescents (M_{age}=13.41, SD_{age}=1.74; 34 male) participated. All participants had an IQ≥70 (M_{ASD}=101.94, SD_{ASD}=16.58; M_{TD}=107.96, SD_{TD}=13.04). ASD diagnosis was confirmed via ADOS-2 (Lord, Rutter, DiLavore, & Risi, 2012). Participants completed the Olweus Bully Victim Questionnaire (OBVQ; Solberg & Olweus, 2003), a measure of peer victimization; the Social Skills Improvement System (SSIS; Elliott & Gresham, 2013), a measure of social behavior; and the Children's Assertive Behavior Scales (CABS; Michelson & Wood, 1982), a measure of social knowledge. Associations between social knowledge and behavior and victimization were assessed via bivariate correlations. Specificity of significant correlations by diagnosis were probed using moderation models with z-transformed variables. The relative contribution of social knowledge vs. behavior in predicting peer victimization was evaluated using a multiple linear regression.

Results: Higher OBVQ ratings of peer victimization was positively correlated with CABS scores, indicating poorer social knowledge (r=.223, p<.05). Higher OBVQ scores were negatively correlated with social behavior on the SSIS (r=-.299, p<.01). Moderation analyses indicated that the relationship between social knowledge and peer victimization was moderated by ASD diagnosis (β =.460, p=.030), such that poorer social knowledge related to increased victimization only in the ASD group (β =.365, p=.002; Figure 1A). Similarly, the relationship between social behavior and peer victimization was moderated by ASD diagnosis (β =-.404, p=.050), such that it was present only in the ASD group (β =-.473, p=.001; Figure 1B). In the ASD group, multiple linear regression indicated that social behavior (β=-.497, p<.01), but not social knowledge (β =.096, p>.05), significantly predicts victimization.

Conclusions: This study suggests that social knowledge and social behavior deficits are related to increased peer victimization in adolescents with ASD, but not TD adolescents. Furthermore, within ASD, self-perception of social behavior, as opposed to social knowledge, more strongly predicts level of peer victimization. Youth with ASD who view themselves as less socially capable are particularly susceptible to instances of peer victimization, above and beyond any risk conferred by not explicitly knowing how to behave appropriately in a given social context.

338 **177.338** Third-Party Sociomoral Evaluations in Children with Autism Spectrum Disorder

T. Li[1], *J. Decety*[2,3], *X. Hu*[4], *J. Li*[5,6], *J. Lin*[7] *and L. Yi*[1], *(1)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (2)Department of Psychology and Child Neurosuite, University of Chicago, Chicago, IL, (3)Department of Psychiatry and Behavioral Neuroscience, University of Chicago, Chicago, IL, (4)Department of Special Education, Beijing Normal University, Beijing, China, (5)Southern China Research Center of Statistical Science, Sun Yat-sen University, Guangzhou, China, (6)Department of Statistical Science, School of Mathematics and Computational Science, Sun Yat-sen University, Guangzhou, China, (7)Mental Health Education &*

Counseling Center, Sun Yat-sen University, Guangzhou, China

Background:
Individuals with ASD have shown preserved abilities in several aspects of moral evaluations (e.g., Blair, 1996; Kretschmer, Lampmann, & Altgassen, 2014), despite their impairments in Theory of Mind (ToM). However, previous findings on moral reasoning in ASD have all built on explicit verbal evaluations of morally-laden scenarios, while the implicit processing underlying them remains undiscovered.

Objectives:

The current study investigates both implicit and explicit processes of third-party moral transgressions using eye tracking in children with ASD and typically developing (TD) controls. We aim to provide new evidence for implicit and explicit moral reasoning in children with ASD in terms of their understanding and sensitivity to the perpetrator's intention, as well as atypical patterns of responses, especially for scenarios involving intentional damage to objects.

Methods:

We modified the moral reasoning task from that created by Decety and colleagues (2012). The paradigm included four experimental conditions and one control condition. A total of four scenarios for the experimental conditions were depicted as follows: (a) a person (perpetrator, the initiator of the action) damaging an object intentionally (object-intentional, OI); (b) a person damaging an object accidentally (object-accidental, OA); (c) a person (perpetrator) hurting another person (victim) intentionally (person-intentional, PI); and (d) a person damaging another person accidentally (person-accidental, PA).The control condition depicted people's daily activities without any pain or damage involved. Each condition consisted of five trials, and each trial consisted of three pictures presented successively to imply actions.

Twenty 4- to 7-year-old children with ASD and nineteen typically-developing controls were shown dynamic visual stimuli depicting intentional or accidental harm to persons or damage to objects. Their eye-movements and pupil dilations were recorded by a Tobii Pro X60 eye tracker. They were asked four questions to evaluate the wrongness of the harmful behavior and the perpetrator performing the actions in each trial, using five-point rating scales.

We defined the fixation durations on the perpetrator and on the victim, with manually drawn areas of interest (AOIs). Children's verbal evaluation, fixation durations and pupil dilations were compared across group and condition using mixed-design ANOVAs.

Results:

We found that (a) children with ASD show implicit processing and autonomic responses to the third-party harms in their eye movements and pupil dilation; (b) children with ASD demonstrated a spared ability to process the intentionality of the perpetrator, reflected by both their explicit evaluations and implicit reactions; and (c) children with ASD showed some abnormal patterns of moral evaluation, especially for the scenarios involving intentional damage to objects.

Conclusions:

Our study indicate a preserved capacity to understand the mental states of perpetrators and an implicit moral sensitivity to the third-party harms in children with ASD. Nonetheless, children with ASD show specific sensitivity and emotional arousal when viewing damage to objects. These findings contribute to the understanding of the underlying mechanisms of moral reasoning in ASD, and its possible association with the autistic symptoms.

339 **177.339** Toward a Cross-Species Measure of Social Motivation: Social Attention during Object Engagement in Autism and Williams Syndrome

C. Weichselbaum[1], *J. Albright*[2], *N. Hendrix*[3], *N. Marrus*[1], *J. Dougherty*[1] *and J. N. Constantino*[1], *(1)Washington University School of Medicine, St. Louis, MO, (2)Virginia Polytechnic Institute & State University, Blacksburg, VA, (3)Marcus Autism Center, Emory University School of Medicene, Atlanta, GA*

Background: Autism Spectrum Disorder (ASD) is characterized by social deficits including reduced social orienting. According to the social motivation hypothesis of autism, this may be due to children with ASD finding social stimuli and interactions less inherently rewarding than typically developing individuals. Conversely, children with the genetic disorder Williams Syndrome (WS) are often hypersocial, suggesting they may find social interaction more rewarding than their typically developing peers. In a recent study examining the social motivation of domesticated dogs as compared to wolves, attentional bias to social stimuli was quantified by presenting animals with a highly engaging object and coding for looks toward the experimenter (vonHoldt et al. 2017). Interestingly, the greater social attention in dogs was associated with structural variants in several genes implicated in WS (vonHoldt et al. 2017), suggesting that attention to social vs. nonsocial stimuli represents a conserved aspect of social motivation across species. Therefore, measurement of this behavior in humans could serve as an informative correlate for future genetic studies of social motivation and its role in the development of ASD.
Objectives: Here we have developed a novel method to assess social motivation in children with ASD and WS, by quantifying their social attention while the child plays with a high-value toy, a competing non-social stimulus.

Methods: We analyzed video clips from the free play section of the Autism Diagnostic Observation Schedule (ADOS), a standardized, semi-structured, play-based interview often used to diagnose ASD. Specifically, we focused on brief segments when the child was actively engaged with a high-value object (an interactive musical toy), and coded the frequency and duration of the child's gaze toward the object, the examiner, and the caregiver. Inter-rater reliability was high (ICC > 0.9). Videos were coded for three groups: a typically developing group, a group with ASD, and a group with WS.

Results: In a small pilot sample (n=6 per group), we found that toddlers with ASD spent significantly less time looking at social partners (caregiver and examiner) compared to typically developing children during periods of engagement with the high-value toy (see figure). While typically developing children frequently alternated their gaze between the toy and social partners, children with ASD looked toward the adults much less frequently. Children with WS were more variable in their social attention, with some behaving more like children with ASD and others more like typically developing children. There was no significant difference in duration of play with the high-value toy across groups, suggesting that it was consistently engaging for all children.

Conclusions: We are currently replicating these findings in a larger dataset which includes both high-risk and low-risk typically developing children, as well as additional ASD and WS participants. Our pilot analyses suggest that a brief behavioral measure pitting a high-value toy against the innate draw of social engagement could serve as a rapid, feasible measure of social motivation, with implications for enhanced clinical

assessment and behavioral phenotyping for genetic research in ASD and WS.

340 **177.340** Turner Syndrome: A New Research Model for ASD in Girls?

J. Wolstencroft[1], *D. H. Skuse*[2] *and W. Mandy*[3], *(1)UCL GOS ICH, London, United Kingdom, (2)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, (3)University College London, London, United Kingdom of Great Britain and Northern Ireland*

Background: Autism Spectrum Disorders (ASD) are rarely diagnosed in high-functioning females with normal/high verbal IQ. Consequently, there have been few studies on this female phenotype across the life-span.
Turner Syndrome (45,X; TS) is a relatively common sex chromosome aneuploidy (4:10,000 live births). Affected females often experience social interaction difficulties that resemble those of idiopathic ASD. Yet most have normal-range verbal intelligence and they typically possess good formal language skills.

Objectives: We compared and contrasted the phenotypic profiles of TS females (5-18 years of age) with an age/VIQ matched sample of females diagnosed with idiopathic ASD.

Methods: Participants with TS (N=70) were recruited nationally from support groups and paediatric clinics. They were participants in the Social Skills and Relationships in Turner Syndrome study (SOAR), but they were not selected because of any previously diagnosed social communication disorder. Participants with idiopathic ASD (N=35) were recruited from the National Centre for High Functioning Autism (NCHFA-London, UK). The idiopathic-ASD and TS groups were matched for chronological age (t(54)=-0.71, p=0.48) and mental age (t(50)=-0.38, p=0.7). All had verbal IQ in the normal range. ASD was diagnosed in all cases by clinicians, using standardized procedures applying DSM-5 criteria. Participants were also rated according to the Strengths and Difficulties Questionnaire (SDQ) and the Social Responsiveness Scale 2 (SRS-2).

Results: 22.6% of TS females were diagnosed with ASD in the course of the SOAR study. There were no significant group differences on SDQ total scores, a broad ranging measure of emotional and behavioural adjustment, but the ASD-TS group were rated as having greater peer difficulties than the idiopathic-ASD group (t(52)=-3.95, p<0.0001). There were no significant group differences on the SRS-2 total score; only 14% of the TS participants obtained a 'normal-range' score. Overall, the TS group with ASD were more impaired than the idiopathic ASD females, in terms of social awareness, social cognition, social communication and autistic mannerisms but they scored similarly for social motivation. Group differences were not statistically significant but effects sizes ranged from small to medium.

Conclusions: 86% of a large and putatively representative sample of TS females, recruited from paediatric endocrinology clinics, experienced autistic-like social interaction difficulties of considerable severity, likely to impact their everyday life. One in five met DSM-5 criteria for an ASD. Phenotypic comparisons with females matched for age and IQ showed a similar range and severity of symptomatology. We provide preliminary evidence indicating females with TS are at high risk of ASD despite normal verbal intelligence. They represent a suitable model syndrome for interventions aimed at remediating social interaction difficulties in females with high-functioning ASD.

341 **177.341** Using Social Stories to Promote Behavior Change for Individuals with Autism Spectrum Disorders: A Scoping Review

D. H. Como[1], *M. E. Goodfellow*[2], *D. Hudak*[2], *L. I. Florindez*[1] *and S. A. Cermak*[3], *(1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background: Social stories are a popular choice of intervention for many professionals to use when working with individuals with Autism Spectrum Disorders (ASD). Social stories have been used in a variety of settings and for a number of purposes, including helping children understand group situations, perceive how others behave or respond, develop self-care skills, academic abilities, and coping skills, and as a behavioral strategy. There have been a number of reviews exploring the quality and efficacy of social story interventions. However, the results of previous publications have highlighted the disparate outcomes of social story research.
Objectives: The objective of this scoping review is to identify, evaluate, and synthesize studies utilizing social story interventions targeting behavior change in individuals with Autism Spectrum Disorders (ASD).

Methods: A search of five databases (PsycINFO, Cochrane Systematic Database, PubMed, CINAHL, ERIC) targeting social stories was conducted. Articles with population term- [(Autis* OR ASD OR Asperger*)] AND intervention term- [("Social Stories" OR "Social Story" OR Social Narrative)] were considered. Inclusion criteria: 1) individuals with Autism, Asperger, PDD-NOS, or Autism Spectrum Disorders; 2) published before February 2018; 3) social story/social narrative as intervention. Exclusion criteria: 1) literature reviews; 2) case studies without intervention; 3) qualitative understanding of user experience; 4) no control or alternate condition; or 5) comparisons of delivery modes (i.e., iPad vs. paper). Article titles, abstracts, and full-texts were independently reviewed by two reviewers; a third reviewer assisted during conflicts until consensus was met.

Results: Results of the systematic search produced 450 abstracts across five databases. After 136 duplicates were removed, 314 original titles and abstracts were screened, and 150 full-texts were evaluated for inclusion. Eighty-eight articles met criteria and were included in the qualitative synthesis. Primary outcomes of each study were identified and sorted into one of two macro-categories based on their aim: *Reduce Disruptive Behaviors* (RDB) (37.5%) and *Increase Desired Behaviors*(IDB) (62.5%). Gray's Social Story fidelity criteria were used to assess intervention strength, and were met in 35% of the articles. The subcategories yielding effective results consistently across multiple studies targeted the following behaviors: aggressive actions, fear/anxiety, verbal protests, identifying emotions, executive functioning, and following directions. Since 2013, the focus of social story interventions has moved from reducing disruptive behaviors toward increasing desired behaviors, at a ratio of 2:5. The overwhelming majority of the articles (92%) are from the U.S, two are from Turkey, and one each from Japan, New Zealand, Thailand, United Arab Emirates and the United Kingdom.

Conclusions: This scoping review highlights how social story interventions are used to promote behavior change for individuals with ASD. The studies included in this review provide support for the use of social stories to improve social engagement through the development and enhancement of a pro-social skills such as recognizing emotions, initiating social contact, and learning how to utilize positive verbal and non-verbal communication abilities. Thus, the findings from this scoping review provide evidence supporting social story interventions as effective in facilitating positive social interactions, promoting regulation, and eliciting behavior change for children with ASD.

342 **177.342** Using Thin Slice Ratings to Measure Social Communication in Children with Autism Spectrum Disorder

K. M. Russell[1], *K. M. Frost*[2] *and B. R. Ingersoll*[2], *(1)Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI*

Background: Behavioral observations are an important source of information regarding social communication behaviors in young children with ASD. The Brief Observation of Communication Change measure (BOSCC; Grzadzinski et al., 2016) was developed as a standardized observational coding system of social communication skills that can be used across intervention trials. Thin slice ratings (TSR), in which very short observations are rated by multiple untrained raters, have been shown to predict a variety of behaviors in children and adults (Baker et al., 2010; Murphy, 2005; Tackett et al., 2016). Recently, they have been used to rate social communication and autism symptomatology in young children with ASD (Hampton et al., 2018; Walton & Ingersoll, 2016), suggesting their potential as an alternative to more time intensive coding systems.
Objectives: The aim of the current study is to examine whether TSR of social communication skills during a parent-child interaction are psychometrically sound and capture similar information to the BOSCC for young children with ASD. We predicted that TSR would be highly correlated with BOSCC scores for the same observation and would show similar relationships to other measures of social communication and demographic variables.

Methods: TSR for 71 children with ASD were completed by 173 undergraduate college students from a psychology research pool. Fourteen groups of 11-15 raters viewed 2-minute clips of a 10-minute parent-child interaction for 4 to 7 different children. Raters used a 5-point likert-type scale to rate each clip on 7 items that were derived from the social communication items of the BOSCC (SC). Each group's item-level ratings for an individual child were averaged to produce TSR for each item. All items were then averaged to produce an overall TSR for each child. Cronbach's alpha based on the average item-level ratings was used to examine internal consistency of the coding scheme. Intraclass correlations (ICCs) based on overall TSR were examined to evaluate inter-rater reliability. Separate one-way random average measures ICCs were run for each group, given groups had different numbers of randomly-selected raters. Bivariate correlations were run to examine concurrent and discriminant validity between overall TSR and the BOSCC-SC, and other measures of social communication and demographic variables.

Results: Cronbach's alpha for the TSR was 0.92. ICCs ranged from 0.75 to 0.98. Overall TSR were significantly correlated with BOSCC-SC ($r = -.69$, $p < 0.01$). In addition, overall TSR and BOSCC-SC scores showed similar relationships to other measures of social communication (i.e. MCDI words produced, VABS-2 communication and socialization age equivalents, and MSEL verbal age equivalents; $p < 0.01$), but not child sex or parent education.

Conclusions: Thin slice ratings of young children with ASD during a parent-child interaction using modified BOSCC-SC items are internally consistent and show a similar pattern of relationships with other measures. Findings suggest TSR may be used to measure child social communication as an alternative to more resource-intensive coding measures. Future studies should investigate whether TSR capture other aspects of autism symptomatology (e.g. restricted and repetitive behaviors) and are sensitive to change.

343 **177.343** Web-Based Measure of SEL Skills Associated with Parent-Reported Social Behavior in Youth with Autism Spectrum Disorders

A. Karls[1], *M. D. Lerner*[2], *N. Russo-Ponsaran*[1], *C. McKown*[1], *E. Kang*[3] *and S. L. Sommer*[3], *(1)Rush University Medical Center, Skokie, IL, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Stony Brook University, Stony Brook, NY*

Background: Social emotional learning (SEL) skills are essential for competent social functioning across youth populations (Crick & Dodge, 1994). While youth with autism spectrum disorders (ASD) often exhibit challenges in aspects of SEL (e.g., emotion recognition, theory of mind; Lozier et al., 2014; Baron-Cohen, 2000), it is unclear how these challenges relate to social functioning as observed by parents. To assess this relationship comprehensively, a tool is needed that evaluates multiple aspects of SEL in the same child. A web-based, modular, self-administered SEL assessment called SELweb has been developed, validated, and normed in general education-placed youth (McKown et al., 2015); effectively measures emotion recognition, theory of mind, social problem solving (SPS), and self-control (McKown, 2018); and is a promising candidate for unraveling the association between SEL and social functioning in ASD.
Objectives: To explore the relationship between SELweb performance and parent-reported social behaviors among youth with ASD.

Methods: Fifty-two verbal children between 6 and 10 years of age (M_{age}= 8.66, SD_{age}=1.38; 40 male; IQ≥85 per KBIT-2; Kaufman & Kaufman, 2004) who met diagnostic criteria on the ADOS-2 (Lord et al., 2012) completed SELweb (Table 1), which yielded standard scores for emotion recognition, theory of mind, SPS, self-control, and an overall SEL composite score (Table 2). A parent completed the Social Skills Improvement System (SSIS; Gresham & Elliott, 2008) for each participant. Using multiple regression analyses, SELweb results were compared to scores on the SSIS, controlling for age and IQ.

Results: The SEL composite score on SELweb predicted the overall SSIS Social Skills score (β=.351, p<.05). This association was largely attributable to the relationship with SSIS responsibility and empathy subscales (both β>.463, p<.01). These associations were, in turn, driven by SELweb's SPS module (β =.372, p<.01; β=.385, p<.01, respectively) and its subcategories of solution preference (β=.332, p<.05; β=.339, p<.05), goal selection (β=.309, p<.05; β=.366, p<.01), and hostile attribution bias (β=.391, p<.01; β=.354, p<.05). Scores on the SPS module and its subcategories were also associated with other SSIS scores, including the autism spectrum scale (all β<-.288, all p<.05).

Conclusions: Results suggest that SELweb performance in youth with ASD is related to several social behaviors as reported by parents, with particularly robust associations with responsibility and empathy. In turn, this effect was driven by SPS abilities, which were also associated with parent-reported ASD symptoms. When considering all aspects of SEL and controlling for age and IQ, it may be the ability to effectively and accurately plan responses to social situations (but not more widely-studied perspective-taking or emotion recognition) that most relates to parent-observed social abilities in youth with ASD, particularly in terms of being well-behaved and showing concern for others. While youth with ASD, then, may exhibit challenges in other aspects of SEL, they may be less directly related to the functional social outcomes ultimately targeted in interventions. The specificity of this finding arises from the use of an assessment tool that permits evaluation of multiple aspects of SEL in the same child – an approach that warrants study in future research.

344 **177.344** Yoga Practice Among Adolescents with Autism Spectrum Disorder: Exploring the Effect on Social Behaviors in Classroom.

M. J. Beaudoin[1], *N. Poirier*[2] *and A. Leroux-Boudreault*[3], *(1)Université du Québec à Montréal, Montréal, QC, Canada, (2)Psychology, Université du*

Québec à Montréal, Montréal, QC, Canada, (3)Université du Québec à Montréal, Montreal, PQ, Canada

Background:
Adolescents with Autism Spectrum Disorder (ASD) may present some difficulties that can be explain by a diagnosis associated with there condition (ex: anxiety disorder, attention deficit and hyperactivity disorder (ADHD), mood disorder) (Simonoff and al., 2008). The percentage estimates of adolescents with ASD meeting the diagnosis criteria of ADHD is about 28% (Simonoff and al., 2008). New avenues are explored to help adolescents with ASD deal with there difficulties, such as yoga therapy, that had demonstrated it efficacity among children with ASD (Kenny, 2002; Koenig and al., 2012; Rosenblatt and al., 2011).

Objectives:

The aim of this study is to explore the efficacity of yoga practice on social behaviors of high school students with ASD.

Methods:

Two groups of six students (n=12) with ASD in two special classrooms frequenting an ordinary Montreal high school, their teachers and the classroom special educator participated to one yoga session per week for 8 weeks. The yoga sessions were animated by a yoga teacher certificated in yoga therapy. Before and after each session, an observation of the student's social behaviors was made. The social behavior referred to the attentive response of the students to a task that the teacher was asking them to do in the classroom. The students evaluated their difficulties with the Behavior Assessment System for Children, second edition, self-reported questionnaire (BASC-2).

Results:

The results indicate that 48 % of the student perceived that they present attention problems. Non-parametric analyses indicate that the social behavior frequencies of those students are significantly higher after the yoga sessions compared to before the yoga sessions, $p < .05$. Of all the students that have participated, 52 % do not report presenting attention problems. For those students, there social behavior frequencies after yoga sessions are significantly higher then before yoga sessions, $p < .05$.

Conclusions:

These findings indicate that yoga can be an effective practice among adolescents with ASD. The effect of the yoga was shown regardless of the attention difficulties perceived by the participants. The results of this study support the findings of Kenny (2002), Koenig and collaborators (2012) as well as Rosenblatt and collaborators (2011) by demonstrating that yoga is a practice that can help improving social behaviors of adolescents with ASD. This research show that integrated yoga sessions in school setting can be an effective way to reinforce the concentration of the students when doing an academic task. Next steps would be to increase the participants and to add a measurement of anxiety before and after the yoga sessions.

345 **178.345** Deletion Impact on General Intelligence Is Similar in Autistic Than in Other Neurodevelopmental Disorders and General Population.

G. Huguet[1], *C. Schramm*[2], *E. A. Douard*[1], *A. Main*[3], *M. Jean Louis*[1], *M. Auger*[1], *G. Schumann*[4], *T. Bourgeron*[5], *Z. Pausova*[6], *S. Karama*[7], *A. Labbe*[8], *T. Paus*[9], *C. Greenwood*[10], *I. Deary*[11] *and S. Jacquemont*[12], *(1)Research Center of UHC Sainte-Justine, Montreal, QC, Canada, (2)University of Montreal, Montreal, QC, Canada, (3)HEC Montreal, Montreal, QC, Canada, (4)King's College de Londres, London, United Kingdom, (5)University Denis Diderot Paris 7, Paris, France, (6)Hospital for Sick Children, Toronto, ON, Canada, (7)Douglas Mental Health University Institute, Montreal, QC, Canada, (8)Département de Sciences de la Décision, HEC Montreal, Montreal, QC, Canada, (9)Departments of Psychology and Psychiatry, University of Toronto, Toronto, ON, Canada, (10)Lady Davis Institute for Medical Research, Jewish General Hospital, Montreal, QC, Canada, (11)University of Edinburgh, Edinburgh, United Kingdom, (12)CHU Sainte Justine, University of Montreal, Montreal, QC, Canada*

Background: Copy number variants (CNVs) classified as pathogenic are identified in 10 to 15 % of patients referred for neurodevelopmental disorders (examples: intellectual disability, autism, ...). However, their effect-sizes on cognitive traits measured as a continuum remain mostly unknown because the vast majority of them are too rare to be studied individually using association studies. In a previous study, we developed a model to predict the effect-size of any deletion on intelligence quotient (IQ). This model was based on data from two general population cohorts. We validated this model by assessing the concordance between our predictions with literature for 15 recurrent CNVs and we estimated that our model has 75% of accuracy.
Objectives: We aim to extend this model to neurodevelopmental disorders, especially autistic populations to better handle the rare and non-recurrent deletions that may explain the low IQ measured in some patients.

Methods: We called CNVs ≥50Kb from genotyping data from 5 general population cohorts (n=17,449) as well as two disease cohorts, the Simons Simplex Collection of autism (n=2,574) and a neurodevelopmental disorder family cohort from CHU Sainte Justine (n=239). General intelligence was measured using different IQ scales or general factor (g-factor) which was computed using principal components analysis of different cognitive scores. Linear and non-linear models investigated functional annotations of genes included in CNVs to identify features explaining their effect-size on IQ. Then, we meta-analysed the results obtained for each cohort. Validation was performed using intra-class correlation comparing IQ predicted by the model to empirical data.

Results: We investigated a total of > 80,000 CNVs covering > 5,000 genes. Effect-size of deletions in disease cohort, including an autistic cohort, is similar to the one we observed in general population. Among 10 functional annotations, constraint scores (in particular the probability of being intolerant to haploinsufficiency-pLI) best explain the effect of deletions on non-verbal IQ with a decrease of 0.17 points Z-score per unit of pLI (CI 95%: [-0.22;-0.13]). The same effect-size was observed for the normalized g-factor with -0.20 Z-score (CI 95%: [-0.26;-0.14]). Effect-size of CNVs was similar across all methods used to measure general intelligence and across general population disease cohorts and complex comorbid clinical cases (neurodevelopmental disorders and/or autism). The concordance between this new prediction and the decrease of general intelligence computed in previous studies on recurrent CNVs is >75%. We did not identify any interactions or non-linear genetic effects on general intelligence.

Conclusions: The effect-size of deletions on general intelligence can be reliably estimated across the genome and is independent of participants' status. Results suggest omnigenic effects of haploinsufficiency and overexpression on general intelligence. This represents a framework to study variants too rare to perform individual association studies and we provide a new online tool for clinicians to estimate the contribution of undocumented CNVs to patient's cognitive deficits in the neurodevelopmental clinic. We hope that the characterization of rare variants will help to better understand the heterogeneity of autism disorder.

347 **178.347** Social and Non-Social Autistic Traits and Autism Domains Are Genetically Dissociable

V. Warrier[1], *R. Toro*[2], *H. Won*[3], *C. Leblond*[4], *F. Cliquet*[5], *R. Delorme*[6], *B. Chakrabarti*[7], *L. G. EU-AIMS*[8], *N. iPSYCH-BROAD ASD Group*[9], *N. The 23andMe Research Team*[10], *D. Hinds*[11], *T. Bourgeron*[12] *and S. Baron-Cohen*[13], *(1)University of Cambridge, Cambridge, United Kingdom, (2)Pasteur Institute, Human Genetic and cognitive function, Paris, France, (3)University of North Carolina, Chapel Hill, NC, (4)Institut PASTEUR, Paris, France, (5)Institut Pasteur, Paris, France, (6)AP-HP, Robert-Debré Hospital, Child and adolescent Psychiatry unit, Paris, France, (7)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (8)EU-AIMS Organization, London, United Kingdom, (9)Aarhus University, Aarhus, Denmark, (10)23andMe Inc, Mountainview, CA, (11)23andMe, Mountain View, CA, (12)University Denis Diderot Paris 7, Paris, France, (13)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: There is some evidence to suggest that the two core domains of autism – social and communication difficulties, and unusually repetitive and restricted behaviour, interests and activities – are dissociable. Autism has traditionally been regarded as a 'syndrome' meaning that these two domains co-occur. The idea that these symptom domains might be independent of one another should not be surprising, given that they seem to entail very different cognitive processes. To date, there is limited molecular genetic evidence in support of the dissociability hypothesis, primarily due to the lack of well-powered molecular genetic studies that investigate the social and non-social domains of autism separately.

Objectives: To investigate if social and non-social autistic traits measured in the typical population and autism domains measured in autistic individuals are genetically dissociable.

Methods: Genetic correlations of autistic traits (systemizing, empathy, social relationship satisfaction, and scores on the Social and Communication Disorders Checklist (5,421 < N < 139,604)), and of RBS-R and ADOS social and communication subscales in 2989 autistic individuals.

Results: Systemizing is positively genetically correlated with autism ($r_g = 0.26 \pm 0.06$; $P = 3.35 \times 10^{-5}$), whilst SCDC, self-reported empathy, friendship and family relationship satisfaction are negatively genetically correlated with autism ($-0.39 < r_g < 0.26$, all $P < 5 \times 10^{-4}$). There is limited shared heritability between the social traits (empathy, friendship and family relationship satisfaction) and systemizing. Clustering analyses of 15 phenotypes that are genetically correlated with autism identified a social cluster with the social phenotypes clustering with each other, measures of intelligence clustering close to each, and neuropsychiatric conditions clustering close to each other. Systemizing did not cluster with any of the phenotypes, and was genetically correlated only with autism and measures of intelligence **(Figure 1A)**. Investigating genetic correlations between friendship satisfaction, empathy, and systemizing among 9 psychiatric conditions, only autism had the combination of negative genetic correlations with both empathy and friendship satisfaction, and positive genetic correlation with systemizing, mirroring the DSM-5 and ICD-11 criteria for autism (**Figure 1B**). Polygenic scores for systemizing are associated with RBS-R scores (Beta = 0.047±0.018, P = 0.010) , but not with ADOS social and communication subscale (Beta = -0.008±0.016, P = 0.60). Genetic correlation between RBS-R scores and ADOS social and communication score is low (r_g = 0.15±0.46, P = 0.74) and significantly lower than 1 (P = 0.034).

Conclusions: Our findings strongly suggest that the two core domains of autism are genetically dissociable, and point at how to fractionate the genetics of autism. We strongly suggest the need to collect deeper phenotypic information and understand potential neural and cognitive convergence of these domains to understand the underlying heterogeneity in and biology of autism.

348 **178.348** Autism Polygenic Scores Are Associated with Trauma and Self-Harm

V. Warrier[1] *and S. Baron-Cohen*[2], *(1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

Autistic individuals experience significantly elevated rates of childhood trauma, and self-harm and suicidal behaviour and ideation (SSBI). It is unclear if polygenic scores for autism are associated the likelihood of experiencing these adverse mental health outcomes, and variables that may mediate and moderate this.

Objectives:

To investigate if polygenic scores for autism are associated childhood trauma and SSBI and identify variables that mediate and moderate these effects.

Methods: Using data from the UK Biobank (105,222 < N < 105,638), we applied polygenic scores for autism, and tested for association with childhood traumatic events and SSBI. The exposure variables were polygenic scores for autism, derived from an independent GWAS of autism. Sex and childhood trauma were moderators. Depression and anxiety symptoms, social relationships and job satisfaction were mediators. The main outcomes were childhood trauma scores, self-harm ideation scores, and self-harm scores.

Results: Polygenic scores for autism were significantly associated with childhood trauma scores (max R^2 = 0.083%, $P < 2 \times 10^{-16}$), and self-harm ideation scores (max R^2 = 0.098%, $P < 2 \times 10^{-16}$), and self-harm scores (max R^2 = 0.12%, $P < 2 \times 10^{-16}$). Male sex significantly negatively moderated the effect of polygenic scores on childhood trauma scores (Beta = -0.025±0.005, $P = 1.59 \times 10^{-5}$) and self-harm scores (Beta = -0.015±0.005, P = 0.007). Childhood trauma scores significantly positively moderated the effect of polygenic scores on self-harm ideation scores (Beta = 0.007±0.002; P = 0.008). Depressive symptoms, and quality and frequency of social interactions were significant mediators of the effect of polygenic scores on autism, with the proportion of effect mediated ranging from 0.23 (95% CI: 0.34 – 0.12) for depression to 0.02 (95% CI: 0.03 – 0.01) for frequency of social interaction.

Conclusions: Our results suggest the risk for SSBI and childhood trauma is partly associated with polygenic scores for autism and point to significant gene-by-environment interactions, with sex and childhood traumatic experiences moderating the effects of SSBI. Finally, our results also identify significant mediators of the effect of polygenic scores on SSBI.

Oral Session - 7A

180 - Screening
1:30 PM - 2:25 PM - Room: 517C

1:30 **180.001** Screening for Autism Spectrum Disorder in 9-Month-Old Infant Siblings

L. A. Sacrey[1], *L. Zwaigenbaum*[2], *S. E. Bryson*[3], *J. A. Brian*[4], *I. M. Smith*[5], *W. Roberts*[6], *P. Szatmari*[7], *T. Vaillancourt*[8], *C. Roncadin*[9] *and N. Garon*[10], *(1)Autism Research Centre, Edmonton, AB, CANADA, (2)University of Alberta, Edmonton, AB, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)isand, Toronto, ON, Canada, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Ottawa, Ottawa, ON, Canada, (9)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (10)Mount Allison University, Sackville, NB, Canada*

Background: Most children with autism spectrum disorder (ASD) remain undiagnosed until age 4 or later (Daniels & Mandell, 2013; Public Health Agency of Canada, 2018). Therefore, identifying and treating children prior to diagnosis to improve lifelong outcomes and lessen financial burden have been emphasized. One method to capture early signs of ASD is through parent report. One such assessment, the 'Autism Parent Screen for Infants' (APSI; Sacrey et al., 2018), was developed as a parent-report analogue of the Autism Observation Scale for Infants (AOSI; Bryson et al., 2008), an observational assessment designed to elicit ASD-related behaviors up to age 18 months.
Objectives: This study examined whether the APSI, administered at 9 months of age, could differentiate high-risk (HR; have an older sibling diagnosed with ASD) infants subsequently diagnosed with ASD from other HR and low-risk (LR; no family history of ASD) infants not diagnosed with ASD.

Methods: *Participants*: Children were grouped based on 3-year diagnostic outcomes: (1) HR infants diagnosed with ASD (HR-ASD; n = 34), (2) HR infants not diagnosed with ASD (HR-N; n=82), and (3) LR infants not diagnosed with ASD (n=62).
Assessments: The APSI is a 26-item parent-report questionnaire that queries early signs of ASD in infants between ages 6 and 18 months. It covers pre-diagnostic behavioral symptoms, including impairments in eye contact, visual tracking, responding to name, imitation, language, social development, joint attention, gestures, play, visual examination of objects, and emotional regulation. Parents completed the APSI when their children were 9 months of age. Clinical best-estimate diagnoses were completed at 3 years of age, using the Autism Diagnostic Observation Scale and the Autism Diagnostic Interview-Revised, by clinicians who were blind to previous assessments. *Statistical Analyses*: Performance on the APSI was compared using a one-way ANOVA with diagnostic group as the independent measure and total score as well as item-level scores as the dependent measures. Group effects for total score and individual items were explored using Benjamini and Hochberg (1995) corrections.

Results: A group effect was seen for total APSI score ($F(2,175)=16.37$, $p<.001$), with the HR-ASD group having higher scores than both the HR-N and LR groups ($ps<.001$; $ds=.74$ and .96, respectively), who did not differ ($p=.12$,$d=.33$). Significant group differences were observed for 16 of 26 APSI items ($ps<.05$), as displayed in Table 1. Importantly, the eight items that distinguished between HR-ASD and the other two groups (who did not differ) were: responding to name, anticipating a social response, eye contact, reactivity, showing interest and pleasure, use of hands/holding objects, unusual repetitive behaviors, and unusual sensory interests.

Conclusions: These results suggest that the APSI may be a viable screening option to identify, among children at familial high risk as early as 9 months of age, those who may require additional follow-up and referrals to specialized services. Utility in LR children in the community remains to be determined.

1:42 **180.002** Leveraging Developmental Trajectories of Broadband Screening to Detect Autism Risk in Primary Care

W. Guthrie[1], *R. T. Schultz*[2] *and J. S. Miller*[1], *(1)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The gap between the typical onset of autism symptoms and the average age of diagnosis remains wide, demonstrating the need for novel screening methods that detect ASD more reliably and at younger ages. Infant-sibling studies suggest that many children later diagnosed with ASD show developmental deceleration in the first two years of life, sometimes before clear autism symptoms emerge. However, this has not yet been demonstrated in low-risk samples so its screening value is unknown. This study leveraged routine developmental screening in primary care to examine whether developmental deceleration is an early indicator of ASD that can contribute to universal screening.
Objectives: Test the hypotheses that (1) developmental deceleration can be detected in a subset of low-risk primary care patients and (2) this pattern confers elevated risk for ASD.

Methods: The Children's Hospital of Philadelphia has conducted universal screening for 10+ years across 31 primary care sites. The Survey of Well-Being in Children (SWYC) Milestones (Sheldrick & Perrin, 2013) is administered at 9, 18, and 24-30 months, according to American Academy of Pediatrics (AAP) guidelines. All patients with at least one SWYC screening and follow-up diagnostic data at ≥4 years were included in this epidemiological cohort, identified from electronic health records (N=32,280). The ASD prevalence rate in this cohort was 2.4%.

Results: Growth mixture models identified distinct developmental trajectories of SWYC scores from 9-30 months; a four-class model provided the best fit. Class 1 (67% of the cohort) had 9-month scores that met age expectations and significantly increased from 9-30 months. This class (average posterior probability [APP]=.92) had a lower probability of a later ASD diagnosis (0.5%) compared to the entire cohort (2.4%). Class 2 (19%, APP=.78) also met age expectations at 9 months, but showed a more modest increase from 9-30 months; the rate of ASD in this class was 1.6%.

In contrast, Class 3 (10%, APP=.81) showed developmental deceleration from 9-30 months and had an elevated rate of ASD (7.1%). Class 4 (4%, APP=.89) had lower 9-month scores and more significant developmental deceleration, with a very elevated rate of ASD (27.0%). Two-thirds of children with ASD were classified into Class 3 or 4 (i.e., sensitivity=74%). Specificity of these developmental profiles was 88%, positive predictive was 13%, and negative predictive value was 99%. Additional analyses will combine SWYC developmental trajectories and M-CHAT/F results to determine if the combination yields more accurate screening than either alone.

Conclusions: These data demonstrate that clear developmental deceleration is detectable through routine developmental screenings, and when this pattern is present, it confers elevated risk for ASD. As such, screening for developmental deceleration in the first two years of life may

improve the status quo of universal screening in primary care. One important benefit of this approach is that it leverages tools pediatricians are already administering as a part of routine clinical care. Though this study used screenings from 9-30 months (given guidelines for screening at these ages), developmental deceleration may be detectable even earlier than 24-30 months with more repeated developmental screenings.

1:54 **180.003** Neonatal and Early Infant Developmental Profiles of High-Risk Siblings of Children with ASD

J. Bradshaw[1], *A. Klin*[2], *W. Jones*[2], *C. Klaiman*[2] *and C. A. Saulnier*[3,4], *(1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (3)Neurodevelopmental Assessment & Consulting Services, Decatur, GA, (4)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA*

Background: In an effort to improve early identification of ASD, prospective longitudinal studies of infant siblings of children with ASD have delineated early development profiles of high-risk infants. These profiles characterize infant development from 12-36 and even 6-36 months of age, identifying cognitive, motor, and language deficits for infants who go on to develop ASD (e.g., Barbaro and Dissanayake, 2012; Landa et al., 2012). Yet, little to no research has examined developmental profiles of high-risk infants in the neonatal and early infant period, from birth to 6 months. An understanding of key developmental differences during this early period, including neurological functioning and cognitive and motor development, will contribute to a mechanistic understanding of the emergence of ASD, ultimately leading to the development of targeted interventions.

Objectives: The current study examines neonatal neurobehavioral functioning and subsequent longitudinal developmental profiles from birth to 6 months of age for high-risk infant siblings of children with ASD (HR) compared to low-risk infant siblings of typically developing children (LR).

Methods: In a prospective, longitudinal design, HR (N=51) and LR (N=49) infants were administered the *NICU Network Neurobehavioral Scales* (NNNS) at 1-month and the *Bayley Scales of Infant and Toddler Development* (Bayley) at monthly intervals between 1 week and 6 months of age. Neurobehavioral functioning at 1 month of age was compared between HR and LR infants using independent sample t-tests. Specifically, measures of attention, regulation, arousal, excitability, and lethargy were examined. Linear mixed models were then used to examine trajectories of cognitive, fine motor, and gross motor development between 1-6 months across HR and LR infants.

Results: Neonatal neurobehavioral functioning was largely comparable across the groups, with the exception of regulation for which LR infants outperformed HR infants ($t(65) = -2.70$, $p = < .01$). Linear mixed models indicated a significant main effect of risk for trajectories of cognitive development ($F(1,341)=3.98$, $p<.05$) and a marginally significant main effect of risk for trajectories of fine motor skills ($F(1,338)=3.80$, $p=.052$). Gross motor development was not different between HR and LR groups ($F(1,338)=0.05$, $p=.829$).

Conclusions: These findings suggest that that infants who are at an increased genetic risk for developing ASD may experience very early developmental vulnerabilities, present as early as 1 month of age, prior to the emergence of social-communication deficits. Regulation abilities, which refer to the capacity to organize motor activity and physiological reactivity, were found to be significantly lower for 1-month-old HR infants. Subsequently, HR infants were found to achieve cognitive and fine motor milestones later than LR infants through the first 6 months of life. Additional research is needed to investigate the possibility that lower regulation abilities contribute to these later delays. Indeed, regulation capacities afford increased opportunity for controlled, organized exploration of the environment, which may foster the emergence and refinement of cognitive and fine motor skills. Overall, this research highlights very early vulnerabilities, possibly grounded in disrupted neurological functioning from birth, that should be further investigated as biomarkers of later-emerging social-communication deficits.

2:06 **180.004** Parental Reports of ASD Proband Functioning Are Associated with Outcomes at 24 Months in Infant Siblings

J. B. Girault[1], *M. R. Swanson*[2], *R. L. Grzadzinski*[3], *M. D. Shen*[1], *S. S. Meera*[4], *J. Pandey*[5], *T. St. John*[6], *A. Estes*[6], *L. Zwaigenbaum*[7], *K. Botteron*[8], *H. C. Hazlett*[1], *S. R. Dager*[6], *R. T. Schultz*[5], *J. N. Constantino*[8] *and J. Piven*[9], *(1)University of North Carolina, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of North Carolina Chapel Hill, Chapel Hill, NC, (4)Carolina Institute of Developmental Disabilities, University of North Carolina at Chapel Hill, Carrboro, NC, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of Washington, Seattle, WA, (7)University of Alberta, Edmonton, AB, Canada, (8)Washington University School of Medicine, St. Louis, MO, (9)*Co-Senior Authors, IBIS Network, University of North Carolina, Chapel Hill, NC*

Background: ASD is heritable and infant siblings of children with ASD are at greater risk for receiving a diagnosis, though it remains unclear whether functioning of the proband is related to dimensional outcomes of the infant siblings.

Objectives: To determine if dimensional parent report measures of developmental functioning and autism symptom severity in probands are related to infant sibling outcomes at 24 months.

Methods:

Participants: Participants were recruited as part of the Infant Brain Imaging Study (IBIS), a longitudinal, multi-site study of brain and behavioral development in children at high-familial risk (HR) for ASD. Data from 406 proband and HR infant sibling pairs were included, in which 92 HR infant siblings were diagnosed with ASD at 24 months (HR-ASD) and 314 were negative for ASD (HR-Neg).

Measures:Parental reports of proband ASD severity were evaluated using the Autism Diagnostic Interview – Revised (ADI-R) and the Social Communication Questionnaire (SCQ), and reports of dimensional adaptive behaviors were collected with the Vineland Adaptive Behavior Scales (VABS). Infant measures of interest included examiner-based language and motor performance on the Mullen Scales of Early Learning (MSEL), Autism Diagnostic Observation Schedule (ADOS) scores, and parental reports from the VABS at 24 months.

Analysis:(1) To determine if proband functioning and severity differed between HR-ASD and HR-Neg groups, an ANCOVA testing for main effects of sibling diagnostic group were employed, adjusting for proband and sibling sex and age at measurement. (2) Robust linear regression was used to predict sibling outcomes at 24 months from proband parental reports adjusting for diagnostic group of the sibling, proband and sibling sex and age at measurement, and interacting effects of proband scores and sibling diagnostic group.

Results: Probands of HR-ASD infants were significantly more impaired than those of HR-Neg infants on the SCQ ($F_{1,356}=5.98$, p=0.016, Cohen's d=0.30)and measures of daily living skills ($F_{1,338}=7.21$, p=0.008,d=-0.31), socialization ($F_{1,337}=5.17$, p=0.024d=-0.23), and communication ($F_{1,337}=5.26$, p=0.023, d=-0.26) on the VABS (**Figure 1**). Across the HR sample, there were significant associations between proband SCQ scores and sibling Adaptive Behavior Composite (ABC) scores from the VABS (b=-0.27, p=0.032), between proband and sibling VABS ABC scores (b=0.34, p=0.004), socialization scale scores (b=0.34, p=0.023), and communication scale scores (b=0.47, p<0.0001). Proband parental reports of language from the

VABS were significantly associated with examiner-based assessments of infant sibling MSEL expressive (b=0.32, p<0.01) and receptive language (b=0.76, p<0.001), as well as parental reports of these measures from the VABS (expressive: b=0.39, p<0.001, receptive:b=0.52, p<0.0001; **Figure 2**). Significant interactions for infant diagnostic group and proband score were found when predicting infant communication (b=-0.36, p<0.01) and receptive language (from VABS: b= -0.29, p=0.021, from MSEL: = -0.74, p<0.001;**Figure 2B,C**). No significant associations were found between proband ADI-R and infant sibling outcomes, proband measures and infant ADOS scores, or proband and infant motor skills.

Conclusions: This study demonstrates that parent reports of proband functioning are associated with categorical diagnostic outcomes and both parent reports and examiner-based clinical assessments of dimensional outcomes in infant siblings.

2:30 **181.001** Testing the Efficacy of the Get SET Early Model As a Mechanism to Reduce the Mean Age of ASD Detection and Treatment Referral

K. Pierce[1], *S. James*[2], *E. Bacon*[1], *E. Skepnek*[2], *E. Leuthe*[2], *C. Barnes*[1], *D. Cha*[1], *L. Outhier*[2], *L. Lopez*[1], *S. Nalabolu*[1], *C. Pham*[1], *V. Gazestani*[3], *A. Cheng*[1], *A. Moore*[1], *E. Courchesne*[3] *and C. J. Smith*[2], *(1)Neurosciences, University of California, San Diego, La Jolla, CA, (2)Southwest Autism Research & Resource Center, Phoenix, AZ, (3)Neurosciences, Univeristy of California, San Diego, La Jolla, CA*

Background: Because many children with ASD begin to show observable signs within the first year, there is an ethical demand for early detection and intervention. While we and other University-based studies have shown that ASD can be detected as early as 12-18 months using parent report screens at well-baby check-ups, surprisingly, the mean age of ASD detection in the US is several years later, around 4 years. CDC studies report this age as even later at 56 months in Phoenix. To address this gap, we created a standardized early detection program within the University of California, San Diego, named *Get SET Early,* which expands on our previous work. Our approach incorporates new elements including a triple screen at 12, 18, and 24 month well-baby visits, and tracking of pediatrician diagnostic impression and referral habits (Figure 1). The goal of the model is to reduce the mean age of ASD detection and treatment referral to be between 12-24 months as standard of care.
Objectives: (1) To determine the feasibility of instituting the *Get SET Early* model, initially created within a University setting, within in a community center in Phoenix; (2) to examine program metrics such as mean age of first comprehensive evaluation in Phoenix in comparison to CDC statistics, and in comparison to our university-based program in San Diego.

Methods: A community–based center in Phoenix (i.e., SARRC) was selected to implement the *Get SET Early* model. The program was established in 2014 by creating an early ASD diagnostic center within SARRC, establishing a network of 109 pediatricians and training them to use a screening tool, the CSBS, and by providing San Diego-established *GET SET Early* program materials and data collection mechanisms. Once a toddler was referred to the program, he/she participated in an evaluation that included the ADOS, Vineland, and Mullen and referred for immediate treatment as appropriate. Program metrics included number of screens administered, age at first diagnostic evaluation, number of toddlers identified with ASD and other delays, and age at last (most recent) diagnosis.

Results: Within just 4 years, 45,289 screens were administered at 12, 18, and 24 month well baby visits. Within toddlers screened at 12 months, the mean age of dx evaluation and treatment referral was 14.78 months. Overall, 520 screen-detected (Figure 2), and an additional 65 toddlers that fell outside validated screen age were evaluated. Within this final sample (N=585), 251 toddlers were diagnosed as ASD, 96 as ASD Features, 71 as LD, 106 as DD, and 61 as false positive (i.e., TD) at their last evaluation. The overall age at first evaluation was 21.8 months, which is similar to program results in San Diego, and is 3 years lower than the CDC reported age of 56 months.

Conclusions: The *Get SET Early* model can be easily implemented in regions with late detection ages. Although the program was established in Phoenix just 4 years ago, it has had a major impact on lowering the first age of diagnosis and treatment engagement by around 3 years.

2:42 **181.002** Validation of a Novel Assessment Instrument for Identifying Autism Spectrum Disorder (ASD) in Children with Visual Impairment

N. J. Dale[1], *E. Sakkalou*[2], *D. H. Skuse*[3] *and A. Salt*[4], *(1)Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom, (2)UCL Great Ormond Street Institute of Child Health, London, United Kingdom, (3)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, (4)Great Ormond Street Hospital for Children, London, United Kingdom of Great Britain and Northern Ireland*

Background: Children with profound or severe visual impairment (VI) are at high risk of developing difficulties in social communication and interaction (prevalence of ASD ~30% in several studies). The administration or coding of existing diagnostic tools depend on vision-dependent items and are therefore inappropriate for this clinical population. A novel observational schedule (the Visual Impairment Social Communication Observational Schedule - VISCOS), drawing on elements of ADOS with novel items and methods which do not require vision function, has been developed and validated for the first time.
Objectives: To investigate the performance of the VISCOS in reliably differentiating children with VI at high risk of ASD from those at low risk according to independent expert clinician formulation. Additional investigations aimed to establish concurrent validity by correlating the VISCOS scores with parent-report questionnaires that address social responses in children.

Methods: Four-to-seven-years-olds (M=5.4 years, SD=10.5 months; range 4.0 years to 7 years 9 months; 59% males), with profound VI (n=15; light perception at best), to severe VI (n=67, M=.98 logMAR) participated. The children engaged in social interaction and play including symbolic play, conversation, auditory story and non-visual theory of mind materials with a trained psychologist assessor, using standard presses designed specifically for children with very low or no vision (VISCOS). Parents filled out the Social Responsiveness Scale (SRS-2) and completed an interview consisting of the Development And Wellbeing Assessment (DAWBA) tool. Items which were heavily vision dependent were removed and scoring adjusted. Presented are preliminary data from 67 children, who were rated by the assessor using VISCOS coding schedule. A paediatrician, expert

in VI and ASD, independently scored children using the video assessments and the parent-reported DAWBA to reach diagnostic formulation (Low Risk of ASD, Borderline, ASD) according to DSM-5 criteria.

Results: The internal consistency of VISCOS-Total items was good (α=.87). Inter-rater reliability was excellent (ICC=.95, p=.0001). Significant positive associations were found between VISCOS-Total and the parent-rated questionnaire SRS-2 suggesting good criterion validity. Clinician formulation showed: Low Risk ASD=65.7%; Borderline=19.4%, and ASD=13.4%. A ROC analysis revealed excellent predictive discriminant validity (AUC=0.92) with a sensitivity/specificity of 0.86 for clinician ratings and identified a VISCOS threshold score for *High Risk for ASD* (≥13.5) or *Low Risk for ASD* (<13.5). Correlations revealed the *High Risk* group had significantly higher reported difficulties than the *Low Risk* group on SRS-2 subscales (p=.005, η^2=.122).

Conclusions: The VISCOS has been designed as the first visual impairment-specific assessment tool for children to support the identification and diagnosis of ASD and social communication difficulties. Results suggest a reliable instrument depicting strong internal coherence, construct validity, inter-rater reliability and predictive discriminant validity. Good criterion/construct validity was demonstrated using the results of the SRS-2 questionnaire. The results of the clinician formulation showed that about 32% of the children were classified as being at high risk of ASD (ASD plus borderline), a percentage similar to that found in other studies. A more accurate diagnostic algorithm is being developed. The profiles of ASD in the context of VI are discussed, providing new insights into non-visual ASD.

2:54 **181.003** DSM-5 Autism Spectrum Disorder Symptom Expression in Toddlers

K. Coulter[1], *H. Boorstein*[2], *M. Barton*[1], *D. L. Robins*[3], *W. L. Stone*[4] *and D. A. Fein*[1], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Center School District 58, Kansas City, MO, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)Psychology, University of Washington, Seattle, WA*

Background: Diagnosing autism spectrum disorder (ASD) in toddlers requires careful interpretation of how the diagnostic criteria are manifested in toddlerhood. An established, widely-used parent interview, the ADI-R, has been shown to sometimes under-diagnose children below 24 months chronological or 18 months mental age (Lord et al., 1993). While toddler-specific algorithms have been published (Kim & Lord, 2012), sensitivity in some samples is as low as 67-70%, with specificity from 82-86% (Kim et al., 2013). In addition, administration of the entire interview is lengthy, placing a significant burden on clinicians, parents, and researchers. Based on the clinical experience of multiple expert clinicians, we developed a briefer interview comprising symptoms and behaviors often observed in toddlers with ASD, and accompanying scoring algorithms aligned with DSM-5 diagnostic criteria, for use during evaluations with young children age 12-36 months.

Objectives: Our aim was to determine which of these toddler-specific questions within each DSM-5 symptom domain most clearly differentiate very young children with ASD from those with other disorders or typical development, and which symptoms are unlikely to be manifested at this age.

Methods: Semi-structured interviews with parents attending a diagnostic evaluation for their child were analyzed to determine which questions within each DSM-5 domain best discriminated children who received an ASD diagnosis from those with another diagnosis or no diagnosis. Participants were parents of 284 toddlers between age 12-36 months (M=19.3) who screened positive on a developmental screening questionnaire and received a developmental/diagnostic evaluation. Seventy-eight children were diagnosed with ASD; 117 received a diagnosis of language delay or global developmental delay, and 89 were typically developing. Fisher's Exact Test was used to determine group differences on each of 45 interview questions. An adjusted alpha value of a=.001 was used to account for multiple comparisons.

Results: **Responses to most interview questions were significantly different** between the ASD, other diagnosis, and typically developing groups. Table 1 lists the items with the largest effect size. In the social domain (DSM-5 criterion A), questions about **initiating joint attention, gaze shifting, and responses to other children** most strongly distinguished diagnostic groups. In the Restricted, Repetitive domain (criterion B), questions addressing **unusual whole-body movements, distress in response to change in routines, presence of restricted interests, and sensory seeking** (vs. hyper- or hypo sensitivity) showed the largest differences. Items that were not different among diagnostic groups included how children respond to their name (though frequency of response to name *was* significant), immediate and delayed echolalia, and distress to minor changes in the environment. We suggest that many young children do not yet have enough language to be echolalic, and their cognitive development may not be sufficient to notice small changes in the environment.

Conclusions: Focusing on how the DSM-5 ASD symptoms are expressed in toddlers can help to optimize evaluation efficiency and shed light on how the core symptoms appear early in development in children who screen positive for developmental disorders.

3:06 **181.004** Improving Parent-Provider Communication and Shared Decision-Making for the Early Identification of ASD: A Qualitative Study

E. Posner[1], *L. V. Ibanez*[1], *J. Locke*[2], *P. Carpentier*[1], *L. Frederick*[2] *and W. L. Stone*[3], *(1)UW READi Lab, Seattle, WA, (2)Speech & Hearing Sciences, University of Washington, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA*

Background:

There is an average delay of two years between first concerns for Autism Spectrum Disorder (ASD) and diagnosis (Sansoti, Lavik, & Sansosti, 2012). As a diagnosis is necessary to access ASD specialized interventions, many children fail to receive these services before the age of three, when it would be most beneficial to their development (Dawson et al., 2010). Disjointed and inefficient communication between parents and health/service providers could be a contributor to this delay, as many parents report being afraid to express concerns due to fearing judgement, while providers are unsure about how to appropriately bring up or respond to ASD concerns (Ryan & Salisbury, 2012). The principles of shared-decision making can mitigate these issues, but past studies have found the use of such models is difficult due to a lack of clear materials and supports (Shields et al., 2012).

Objectives:

Our aim was to characterize the challenges and facilitators for effective communication between parents and providers about early ASD concerns in order to develop tools to promote shared-decision making.

Methods:

Twenty-three parents of young children diagnosed with ASD participated in 3 focus groups, 2 conducted in English and 1 in Spanish. Participants answered a series of pre-determined, open-ended questions and prompts related to the diagnostic process and obstacles they encountered accessing services. Focus groups were audio-recorded, transcribed, and coded using the grounded theory approach to find common themes among the participants' responses. Two independent coders reviewed the transcriptions and inter-coder reliability was reached.

Results:

Eight themes were found (underlined; see Table 1). Child characteristics that generated parental concerns included those related to core ASD deficits (e.g., poor eye contact, social interactions) and developmental delays (e.g., language delay). When parents raised the concerns to others (e.g. providers, spouses), their responses ranged from dismissive to disbelieving to affirming. If ASD concerns were raised by others, the delivery was usually gentle, but sometimes poor and unwelcome. Parental reactions when others raised concerns ranged from fear to anger to relief, but all parents generally took action once their providers made recommendations/referrals. Parents' lacked in-depth prior knowledge of ASD and would use the internet and library to seek information on ASD, which, at times, led to them feeling overwhelmed. Barriers to acting on concerns included providers' dismissal of concerns, parental hesitation, language and cultural barriers, and issues with the service delivery system (e.g., long diagnostic waitlists), while appropriate referrals, resources, and support/validation from the child's providers acted as facilitators to acting on concerns. Parents' recommendations to providers included increased training in ASD, increased sensitivity and responsiveness to parental concerns, and concise, informative written materials about ASD, the diagnostic process, and interventions.

Conclusions:

These findings highlight the role that shared decision-making principles may play in improving the early detection of ASD. Results have immediate implications for strategies providers can use in discussing ASD concerns and possible next steps and for the development of shared decision-making materials.

1:30 **182.001** Investigating Brain Response to Speech in 6- and 7-Month-Old Infants: Evidence for Atypical Statistical Learning in Infants at High Risk for ASD

M. G. Pecukonis[1], *K. L. Perdue*[2], *H. Tager-Flusberg*[1] *and C. A. Nelson*[2], *(1)Psychological and Brain Sciences, Boston University, Boston, MA, (2)Boston Children's Hospital, Boston, MA*

Background: Statistical learning is a mechanism of language acquisition that may be atypical in ASD (Romberg & Saffran, 2011). Previous studies have investigated statistical learning by measuring changes in brain activity across trials as infants listen to repeated stimuli. When listening to repeated patterned speech, typically developing (TD) neonates exhibit increased brain activity overtime (Gervain et al., 2008). By 3-months, TD infants exhibit suppressed brain activity overtime, but infants at high risk for ASD do not exhibit changes in brain activity overtime (Edwards et al., 2017). It is however unknown whether these high risk infants continue to exhibit atypical statistical learning as they age, and whether this is early brain activity predicts language abilities later in development.
Objectives: The present study investigated whether 6- and 7-month-old infants at low and high risk for ASD exhibit neural evidence of statistical learning when listening to patterned versus non-patterned speech, and explored whether early brain response predicts receptive language abilities at 24-months.

Methods: 26 (14M, 12F) low risk control (LRC) and 12 (6M, 6F) high risk for ASD infants (HRA-), ages 6 months;5 days to 7 months;28 days, listened to two syllable sequence types, patterned (ABB; "ba-ga-ga") and non-patterned (ABC; "ba-ga-lo") speech, while wearing a fNIRS cap. HRA- infants had an older sibling with ASD, but no ASD diagnosis by 24-months. All infants provided data from 16+ trials. Change in oxyhemoglobin concentration (OxyHb) over the 16-second trial period was extracted and averaged across the first four trials and last four trials (trial blocks) after motion artifact correction. This process was repeated for two regions of interest (ROIs), left anterior and right anterior (Figure 1.b), and for both syllable sequence types. At 24-months, infants returned to complete the Mullen Scales of Early Learning to assess language.

Results: Results of a 2x2x2x2 mixed factorial ANOVA revealed a significant interaction effect between ROI, time, and group ($F(1,36)=4.277$, $p=.046$). Collapsing across both syllable sequence types, LRC infants had greater OxyHb response ($M=.121x10^{-3}$) than HRA- infants ($M=-.013x10^{-3}$) during the first trial block within the left anterior ROI (Figure 1.a). LRC infants had decreased OxyHb in response to speech during the last trial block ($M=.010x10^{-3}$) versus the first trial block ($M=.121x10^{-3}$) within the left anterior ROI. There were no significant differences in OxyHb response during the first trial block ($M=-.013x10^{-3}$) versus the last trial block ($M=.084x10^{-3}$) for HRA- infants within either ROI. Additionally, OxyHb response to patterned speech during the first trial block within the left anterior ROI was significantly correlated with Mullen receptive language scores at 24-months ($r(30)=.438$, $p=.016$; Figure 2).

Conclusions: 6- and 7-month-old TD infants exhibited left-lateralized suppression of brain activity as they listened to repeated stimuli, which may reflect successful stimulus encoding of both patterned and non-patterned speech (Issard & Gervain, 2018). In contrast, HRA- infants did not exhibit changes in brain activity overtime, which may indicate atypical statistical learning within the broader ASD phenotype. Future studies should continue to investigate whether early brain response to speech predicts later language abilities in high risk populations.

1:42 **182.002** Changes in Amygdala and Hippocampus Volumes Among Adolescents with Autism Spectrum Disorder over the Course of the PEERS® Social Skills Intervention

A. Arias[1], *A. Barrington*[2], *A. J. McVey*[1], *H. K. Schiltz*[1], *A. D. Haendel*[3], *B. Yund*[4], *A. V. Van Hecke*[5], *W. Krueger*[6] *and M. Carlson*[7], *(1)Marquette University, Milwaukee, WI, (2)Biomedical Engineering, Marquette University, Milwaukee, WI, (3)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (4)Psychology, University of Wisconsin Milwaukee, Milwaukee, WI, (5)Psychology, Marquette University, Milwaukee, WI, (6)Speech Pathology and Audiology, Marquette University, Milwaukee, WI, (7)Education, Marquette University, Milwaukee, WI*

Background: Amygdala and hippocampus volume comparisons between adolescents with and without autism spectrum disorder (ASD) have been mixed (e.g., Groen et al., 2010; Schumann et al., 2004). Further study is needed to better understand these findings. Additionally, adolescents with ASD who receive a well-validated social skills intervention have demonstrated neurological changes, via EEG, coinciding with improvements in social behavior (Van Hecke et al., 2013). No known study, has examined volumetric change of brain structures in ASD over the course of such an intervention.

Objectives: 1) Compare amygdala and hippocampus volumes for groups of adolescents with and without ASD before intervention. 2) Examine changes in these regions across the Program for the Education and Enrichment of Relational Skills (PEERS; Laugeson & Frankel, 2010) using a randomized controlled trial (RCT).

Methods: Thirty-two male adolescents (23 ASD, 9 typically developing (TD)) aged 11-16 participated. See Table 1 for descriptive statistics and volume means. An RCT (experimental (EXP) vs. waitlist control (WL)) of PEERS® was conducted for the ASD group. Structural MRI scans were collected twice (before and after PEERS® for the EXP group) using a GE 3T scanner. Freesurfer Autorecon Processing (Fischl et al., 2002) was used for whole brain structural segmentation. MATLAB (The Mathworks, Inc, 2018) was employed to extract bilateral amygdala and hippocampus volumes.

Results: One-way ANOVAs revealed no significant difference between groups on amygdala or hippocampus volumes before intervention. Repeated measures MANOVAs for Time (pretest vs. posttest) by Group (EXP vs. WL vs. TD), revealed a Time by Group interaction for amygdala volume (Wilks' Lambda = .48, $F(8,72) = 3.95$, $p < .001$). Univariate follow-up showed that the interaction effect was upheld for right and left amygdala volumes. Paired sample *t* tests demonstrated a decrease in right ($t(15) = 2.97$, $p = .010$) and left ($t(15) = 4.43$, $p < .001$) amygdala volumes in the EXP group across intervention; no significant changes were found for the WL group. Conversely, left amygdala volume increased for the TD group ($t(8) = -3.31$, $p = .011$) across time. No significant effects were found for hippocampus volumes. Table 2 shows the descriptive statistics, *F* values, and significance levels for the univariate follow-ups.

Conclusions: Significant decreases were uncovered for bilateral amygdala volumes for the adolescents with ASD who received the intervention, whilst no significant changes were found for those who did not. The PEERS® intervention, shown to improve social behavior (Laugeson et al., 2009), may contribute to changes in amygdala volume. Furthermore, these changes in brain structure and behavior may dynamically and transactionally contribute to maintained overall outcomes observed after PEERS® for adolescents with ASD. Significant increases uncovered in the left amygdala volume for the TD adolescents are likely due to a maturation effect, as left amygdala volume has shown increases in TD males during adolescence (Neufang et al., 2009). No significant changes were found for bilateral hippocampus volumes, thus social behaviors targeted by PEERS® may be centered in the amygdala.

1:54 **182.003** Social Gestures Are Differentially Related to Brain GABA Levels between Children with Autism and Typically Developing Children

N. A. Puts[1,2], *A. D. Harris*[3,4], *G. Oeltzschner*[2,5], *M. Mikkelsen*[2,5], *R. A. Edden*[1,2] *and S. H. Mostofsky*[6], *(1)Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (2)F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, (3)Radiology, University of Calgary, Calgary, AB, Canada, (4)Child and Adolescent Imaging Research Program, Alberta Children's Hospital Research Institute, University of Calgary, Calgary, AB, Canada, Calgary, AB, Canada, (5)Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, (6)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD*

Background: Autism Spectrum Disorder (ASD) is characterized by impairments in social cognition, communication, and repetitive behaviors. Motor abnormalities are common in ASD and have been linked to social and communicative features of the disorder. Praxis - the performance of complex gestures with a communicative or functional purpose, has been shown to be impaired in ASD and has a large impact on quality of life. The inhibitory neurotransmitter GABA plays an important role in regulating motor behaviors and is implicated in ASD pathophysiology, but the link between GABA and autism-related dyspraxia is unclear.

Objectives:Here, we assessed praxis and measured GABA levels in the sensorimotor cortex of typically developing children and children with ASD using edited Magnetic Resonance Spectroscopy. We hypothesize that children with ASD show worse praxis, and that better praxis performance is correlated with higher sensorimotor GABA levels.

Methods: Data were acquired in 24 children with ASD (10.52 ± 1.25 years, 6F) and 26 TDC (10.11 ± 1.38 years; 8F). Subject and parental consent were obtained under local IRB approval. Diagnosis was confirmed using the ADOS-2. *Praxis:* A pediatric version of the Florida Apraxia Battery was used to examine performance of skilled gestures, known to robustly discriminate children with ASD and TDC. Total percent correct and total error scores were used. *MRI:* GABA-edited MR spectra were acquired from $(3\ cm)^3$ voxels over the right primary sensorimotor cortex using MEGA-PRESS on a Philips 3T 'Achieva' (TE/TR 68/2000 ms, 320 transients; 10 min) and analyzed in Gannet.

Results: Mean praxis percentage correct (ASD; 52.1 ± 15.21, TDC; 75.93 ± 10.94, $p < 0.001$) and errors (ASD; 42.3 ± 15.95, TDC 20.57 ± 9.87, $p < 0.001$) differed significantly. GABA values were significantly lower in ASD, as previously shown. TDC showed a negative correlation with praxis percentage correct (-0.62, p = < 0.01), whereas there was trend towards a positive correlation in ASD (0.21, p = 0.12; *Figure 1A*). TDC showed a positive correlation between GABA and praxis errors (R – 0.6, $p < 0.001$; *Figure 1B*). Children with ASD showed a negative trend (R = -0.25). The correlations were significantly different between cohorts (Fisher r-to-z, $p < 0.01$). We explored whether an inverted u-shape (quadratic fit) fit the data across all participants, but significance did not reach alpha of 0.05 ($R^2 = 0.078$, p =0.06; *Figure 1C*). There were no significant differences in data quality.

Conclusions: GABA is differentially related to praxis performance in children with ASD and TDC. It is not quite clear how to interpret this finding, but the correlations are robust in TDC. Additional resting-state-fMRI, or left-hemisphere GABA levels, might elucidate this relationship. Within TDC, increased GABA levels may reduce gesture performance by suppressing SMA/PMC function to properly plan and execute movements, whereas in ASD, pathologically-reduced GABA may hinder efficient encoding of motor commands and ultimately impair the performance of complex gestures with a communicative or functional purpose, contributing to the autistic phenotype. Understanding the GABA system in ASD is important for developing future novel targets for patient-specific treatment.

2:06 **182.004** EEG Coherence Changes Related to the PEERS® Intervention: Evidence of Neuroplasticity

A. D. Haendel[1], *A. Barrington*[2], *B. Magnus*[3], *A. J. McVey*[4], *B. Dolan*[5], *K. Willar*[6], *A. Carson*[7], *A. Arias*[4], *N. Johnson*[8], *M. Jones Moyle*[9] *and A. V. Van Hecke*[3], *(1)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (2)Biomedical Engineering, Marquette University, Milwaukee, WI,*

(3)Psychology, Marquette University, Milwaukee, WI, (4)Marquette University, Milwaukee, WI, (5)Medical College of Wisconsin, Milwaukee, WI, (6)Stanford University, Stanford, CA, (7)Pediatrics, Autism Center, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (8)Nursing, Marquette University, Milwaukee, WI, (9)Speech-Language Pathology & Audiology, Marquette University, Milwaukee, WI

Background: There is consensus that neurological differences present in people with autism. Furthermore, theories emphasize the mixture of hypo- and hyper-connectivity as a neuropathology in autism spectrum disorder (ASD) (O'Reilly, Lewis, & Elsabbagh, 2017). Literature examining changes in neurological connectivity as a result of a well-validated social skills intervention, however, is limited.
Objectives: The current study examined changes in EEG coherence across the Program for Education and Enrichment of Relational Skills (PEERS®) for adolescents with ASD with the following aims: 1) to examine changes in neural connectivity among adolescents with ASD who received PEERS® (experimental group; EXP) versus those who did not (waitlist control group; WL), 2) to evaluate whether changes in EEG coherence were related to behavioral changes.

Methods: One-hundred ten adolescents with ASD ages 11-16 years, with an IQ ≥ 70, participated in a randomized controlled trial of the PEERS® intervention. Autism diagnosis was confirmed via the ADOS-G (Lord et al., 2001). Electroencephalogram (EEG) data were collected using a 3-minute eyes-open resting state paradigm at two timepoints (pre- and post-intervention for the EXP group). At both timepoints, adolescents completed the Test of Adolescent Social Skills Knowledge(TASSK) and Quality of Socialization Questionnaire(QSQ-A); caregivers completed the Social Responsiveness Scale(SRS) and Social Skills Improvement System(SSIS). EEG data from eight regions of interest: frontal, temporal, parietal, and occipital lobes, in each hemisphere, were calculated and averaged (see Figure 1). Magnitude Squared Coherence was calculated using MATLAB MVDR method for all of the possible pairings (28) in the alpha band (pre and post). Path Analyses were used to investigate correlated outcomes and covariates.

Results: Significant differences were found between the EXP and WL groups at post in OL-TL coherence (β = 0.20, p < .01), controlling for Time 1. Significant effects of Income were found on EEG coherences at post in OR-FR (β = -0.13, p < .005), OR-PL (β = -.29, p < .01), OR-TL (β = -0.27, p < .003), OR-FL (β = -0.14, p < .001), and OL-OR (β = -0.30, p < .005). ADOS-G Total score was a predictor of EEG coherences at post in TR-PR (β = -0.27, p < .01), OR-TR (β = -0.25, p < .009), OL-TL (β = -0.27, p < .006). The residualized post score in the FR-PR coherence pair was significantly related to the Social Skills subscale of the *SSIS* at post (β = .30, p < .002). Significant effects of OL-PL (β = .32, p < .002), and OR-TR residualized coherence (β = .36, p < .008) were found on QSQ-A scores at post.

Conclusions: Results indicated that adolescents with ASD exhibiting more severe symptoms of autism, showed less coherence in "short-range" EEG pairings in social brain areas. After receiving PEERS®, those adolescents exhibited changes in an exemplar "short-range" coherence pair in left occipital-temporal regions that was linked to changes in their social knowledge and behavior. The study's results provide neural evidence for the initial brain differences in ASD being affected by the PEERS® social intervention; therefore, supporting the theory of neuroplasticity.

2:30 **183.001** Relationships between Auditory ERP Responses and Caregiver-Reported Sensory Behaviours in Young Children with Autism Spectrum Development

P. Dwyer[1,2], *R. De Meo*[2], *C. D. Saron*[2] *and S. M. Rivera*[1,2,3], *(1)Department of Psychology, University of California, Davis, Davis, CA, (2)Center for Mind and Brain, University of California, Davis, Davis, CA, (3)MIND Institute, UC Davis Medical Center, Sacramento, CA*

Background: Sensory processing differences in Autism Spectrum Development (ASD) are related to quality of life (Lin & Huang, 2017). These sensory processing differences are heterogeneous, and there have been calls to explore this heterogeneity multimodally (Uljarević et al., 2017). Previous multimodal investigations of sensory processing in ASD using both questionnaires and ERPs have generally included broad age ranges or used smaller sample sizes.
Objectives: The present study aims to explore relationships between auditory ERP responses and caregiver-reported sensory behaviours in a large sample. To allow exploration of loudness-dependency in ERP responses, stimuli were delivered at multiple loudness levels.

Methods: ERPs to auditory stimuli were investigated in 108 young participants with ASD (90 male, M_{Age} = 38.80mos, SD_{Age} = 6.17mos). While watching a quiet video, participants heard, via headphones, brief tones randomly varying in loudness of 50, 60, 70 or 80 dB SPL (200-300 trials/intensity) at an ISI randomly varying between 1-2s. 61-channel EEG was sampled at 1000 Hz. The global field power (GFP) was used as an index of neural response strength. Participants' caregivers completed all seven Short Sensory Profile (SSP) subscales. Time-wise one-way ANCOVAs were conducted on ERP global field power with loudness as a factor and (separately) SSP total and subscale scores as covariates. Only effects with a p-value ≤ 0.01 sustained for ≥20ms are reported; main effects of loudness are not reported. Correlations between SSP scores and GFP in different loudness conditions were used to probe significant effects. Scores on items from subscales on which effects were found were then run as covariates.

Results: An interaction emerged between SSP total scores and loudness (105 – 133ms); less typical sensory behaviours were associated with higher GFP amplitudes in the 70 dB condition (r = -.28, p = .005). In a partially overlapping window, an interaction emerged between the SSP Auditory Filtering subscale and loudness (76 – 131ms); auditory filtering problems were associated with higher GFP amplitudes in the 80 dB (r = -.24, p = .01) condition. Interactions also emerged between loudness and scores on two items on the subscale, specifically those relating to distraction and trouble functioning (72 – 135ms) and difficulty working (81 – 130ms) amid background noise. Correlations yielded similar results to those observed on the complete subscale. Finally, an interaction emerged between Visual/Auditory Sensitivity and loudness (298 – 336ms); greater sensory sensitivity was associated with lower GFP amplitudes in the 80 dB condition (r = .29, p = .003). No other time-wise ANCOVA effects survived outlier removal.

Conclusions: The presence of loudness x SSP interactions emphasizes the importance of considering how sensory response patterns may be affected by the loudness of sensory stimuli. Early in processing (~75-135ms), difficulty with background noise appeared to be related to a stronger response to louder sounds, which could reflect difficulty inhibiting responses to these sounds. Surprisingly, later in processing (~300ms),

visual/auditory sensory sensitivity was associated with a weaker neural response to louder sounds.

2:42 **183.002** Individual Differences in Neural Response to Own Name Heard in Noise across Minimally Verbal and Verbally Fluent Adolescents with Autism

S. Schwartz[1], *L. Wang*[2], *B. Shinn-Cunningham*[3] *and H. Tager-Flusberg*[4], *(1)Graduate Program for Neuroscience, Boston University, Boston, MA, (2)Biomedical Engineering, Boston University, Boston, MA, (3)Carnegie Mellon University, Pittsburgh, PA, (4)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Failure to effectively process salient speech in noisy settings could be both a significant contributor to and a reflection of communication and auditory filtering processing issues observed in many individuals with autism. However, research on these issues has been limited by a lack of neuroimaging research on individuals at the minimally verbal end of the spectrum.
Objectives: We sought to measure, across the entire autism spectrum, neural EEG response to one of the most salient speech sounds – one's own name – when presented in multispeaker noise. For those on the autism spectrum, how does atypical response to own name in noise vary with the individual's communication abilities? How do responses correlate with phenotypic descriptions of the individual's success in filtering speech from noise in everyday settings?

Methods: 38 adolescents with autism (26 M), ages 13 to 22 years, with a range of communication abilities from minimally verbal to verbally fluent, participated. Autism diagnoses were confirmed with the ADOS-2 or Adapted ADOS (Lord et al., 2012; Hus et al., 2011). We additionally collected the Vineland-3 Receptive Communication Subscale and Short Sensory Profile Auditory Filtering Subscale (Sparrow et al., 2016; Tomcheck & Dunn, 2007). 22 typically developing (TD), age-matched adolescents (14 M) served as a reference group to determine the spatial and temporal regions of interest for our autism-specific EEG analyses. For the EEG experiment, each participant heard their own name and two other participants' names as a part of an 8 dB signal to noise multispeaker scene. For analyses, we compared differential response to own name relative to one other name. Peripheral hearing was confirmed as intact using an auditory brainstem measure.

Results: TD participants had a negative differential response from 100 to 300 ms post stimulus along fronto-central electrodes and a positive differential response in a similar time window along left temporal electrodes. They also had a positive differential response from 500 to 600 ms along parietal-occipital electrodes. When we examined this neural response within these reference-defined spatial and temporal components in our autism group, we found that more typical neural response corresponded with better receptive communication and auditory filtering skills. Early fronto-central differential response negatively correlated with receptive communication ($p=0.02$), early left temporal differential response positively correlated with receptive communication ($p=0.01$), and late parietal-occipital response positively correlated with auditory filtering ability ($p<0.001$). Results were not significantly influenced by number of accepted EEG trials.

Conclusions: This study is the first to demonstrate reduced early stage encoding of salient speech and diminished late stage attentional orienting to salient speech in individuals on the autism spectrum who have been characterized phenotypically as having poor communication skills and auditory filtering abilities. This work lays a foundation for uncovering the neural underpinnings of communication and auditory filtering processing issues in autism. Our results highlight the importance of capturing brain-behavior interactions through the measurement of individual differences within a heterogeneous sample of people with autism.

2:54 **183.003** Distinct but Effective Neural Networks for Facial Emotion Recognition in Individuals with Autism : A Deep Learning Approach

J. M. Mayor Torres[1,2], *T. Clarkson*[3], *C. C. Luhmann*[1], *G. Riccardi*[2] *and M. D. Lerner*[4], *(1)Stony Brook University, Stony Brook, NY, (2)Department of Information Engineering and Computer Science, University of Trento, Trento, Italy, (3)Psychology, Temple University, Philadelphia, PA, (4)Psychology, Stony Brook University, Stony Brook, NY*

Background: Individuals with Autism Spectrum Disorder (ASD) evince deficits in facial emotion recognition (FER; Lozier et al., 2014). However, it is unclear if these deficits result from a failure to encode FER, or to deploy correctly-encoded information in making FER judgements (Yang et. al 2018). Deep-learning methodologies, such as Deep Convolutional Neural Networks (Deep ConvNets), utilize a data-driven approach to isolate neural networks involved in encoding emotional faces using single-trial electroencephalography-based (EEG) classification in typically-developing (TD) individuals (Schirrmeister et. al 2017). However, the extent to which Deep ConvNets can determine whether individuals with ASD correctly-encode FER using similar neural networks to their TD peers remains unclear.
Objectives: (1) Examine accuracy of a Deep ConvNet classifier in classifying neural responses to four different emotions (*happy, sad, angry* and *fear*), and (2) detect differences in neural networks involved in FER in individuals with and without ASD.

Methods: Thirty-six TD, and twenty-nine ASD individuals (M_{age}=13.48, SD_{age}=1.894, 44 male; ADOS-2-confirmed; Lord et. al 2012) completed an EEG FER task (DANVA-2; Nowicki 2004). Each participant viewed 48 faces x 752 samples x 30 channels. Trials were segmented 0-1500ms post-stimuli and pre-processed using the PREP (Bigdely-Shamlo et. al 2015) and ADJUST (Mognon et. al 2011) pipelines. A ZCA whitening normalization (Coates & Ng, 2012) was applied constructing a 752x30 image/trial. The Deep ConvNet received images composed of 2 conv-pool layers: (1) a convolutional layer (kernel size: 100x10, filters: 32) and a pooling layer (size: 5x2; 2 stride), and (2) a convolutional layer (kernel size: 20x5; filters: 64) and a pooling layer (size: 2x2; 2 stride). The final fully-connected layer (1024units) was flattened to 4 softmax-derived probabilities-one/class. Accuracy of classifying FER neural responses using the Deep ConvNet was calculated by grouping all the true-positives from the confusion matrix/48 faces. To determine which channels are needed to accurately classify FER, occlusion analyses were used (Zeiler & Fergus, 2014) resulting in 19 possible spatial combinations spanning 5 time-ranges.

Results: Individuals with ASD performed worse on the FER task ($p's<0.05$). The Deep ConvNet classifier successfully distinguished FER neural responses with high accuracy (>0.85; Figure 1,A;B) in both groups, indicating successful encoding occurred. Encoding of FER measured by the Deep ConvNet performance was higher than behavioral FER performance in ASD ($p's<0.001$, Figure 1.C). Occlusion analyses indicated the importance of fronto-temporal regions for TD (Figure 1.D), but left-temporal region for ASD (Figure 1.E), suggesting distinct network engagement in FER in ASD.

Conclusions: The Deep ConvNet was a robust EEG single-trial classifier obtaining high accuracies in classifying correctly-encoded neural responses to FER in ASD. Results suggest that individuals with ASD successfully encode FER using left-temporal networks, which are distinct networks from their TD peers. However, despite accurate encoding, individuals with ASD experience difficulties deploying the correctly-encoded information

needed to accurately perform FER tasks behaviorally. Such findings emphasize that individuals with ASD can indeed encode FER, but do not reliably use this information to perform FER tasks.

3:06 **183.004** Increased Phase-Amplitude Coupling in Children with Autism at 18, 24, and 36 Months

M. Mariscal[1], *A. R. Levin*[1], *H. Tager-Flusberg*[2] *and C. A. Nelson*[3], *(1)Neurology, Boston Children's Hospital, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background: Phase-Amplitude Coupling (PAC), the modulation of higher frequency activity by the phase of lower frequency activity, can be derived from the nested oscillations seen in electroencephalography recordings. PAC may serve as a mechanism for the processing of information as well as for functional connectivity in the brain[1]. Greater PAC has been demonstrated in children with autism spectrum disorder (ASD) with an average age of 9.5 years[2].

Objectives: Here we examine if and when differences in PAC emerge through infancy and early childhood among children at high familial risk who develop ASD, as compared to those who develop typically.

Methods: Baseline electroencephalography (EEG) data was collected in infants at 3, 6, 9, 12, 18, 24, and 36 months of age as a part of a prospective, longitudinal investigation (n=108; not all participants provided useable data at each time point). Participants were at a high risk for autism (HRA) by virtue of having an older sibling with ASD. We measured PAC across multiple frequency combinations for each individual at each time point. Diagnosis of ASD(+) or lack thereof(-) was determined at 24-36 months using the Autism Diagnostic Observation Schedule (ADOS) and best clinical estimate (HRA+: n = 35; HRA-: n = 73).

Results: The HRA+ group shows greater PAC ($p < .05$, independent samples Mann-Whitney U test) than the HRA- group at 18, 24, and 36 months. Differences were not significant in the 3, 6, 9, and 12 month age groups.

Conclusions: We find increased PAC in children later diagnosed with ASD, beginning at around 18 months. We find children later diagnosed with ASD are not born with, but develop, increased PAC. Notably, the timing at which PAC becomes excessive in the HRA+ group is similar to the timing at which symptoms of ASD tend to become more prominent.

Oral Session - 9A
Interventions - Non-pharmacologic - Infant, Toddler, and Preschool
184 - Early Intervention
1:30 PM - 2:25 PM - Room: 516ABC

1:30 **184.001** Parent and Toddler Outcomes from a Wide-Scale Community Implementation of the Social ABCs Parent-Mediated Intervention

J. A. Brian[1], *I. Drmic*[2], *E. M. Dowds*[3], *C. Roncadin*[2], *A. Solish*[1], *C. Shaver*[4], *L. Zwaigenbaum*[5] *and S. E. Bryson*[6], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (4)Hamilton Health Sciences, Hamilton, ON, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)Dalhousie University, Halifax, NS, Canada*

Background: Advances in early detection of ASD in the first years of life have motivated development of early intervention models directly targeted to the developmental needs of the toddler years. Several such models have demonstrated efficacy based on randomized control trials in controlled research settings. Next steps involve scaling up and wide-scale implementation.
Objectives: To evaluate the effectiveness of a parent-mediated intervention for toddlers with confirmed or suspected ASD in a large-scale community implementation.

Methods: Social ABCs parent-mediated intervention is one of four evidence-based models included in a government-funded pilot demonstration initiative currently underway in four regions of Ontario, Canada. The Social ABCs developers ("expert team") trained 5 front-line staff ("coaches") to deliver the Social ABCs parent coaching through the Ron Joyce Children's Health Centre, the regional autism intervention service-provider in Hamilton Ontario (population ~750,000). Coaches attained fidelity of implementation and coaching, and 90 families have completed the 12-week coaching program to date (n > 120 anticipated by April 2019, for presentation at INSAR). To date, 159 toddlers have been enrolled (111 boys, 48 girls); age range: 15-34 months (*M* age = 25.4 months, *SD* = 4.16). Data were analyzed for those children who had completed week 12 (n = 90), including video-coded indices (parent implementation fidelity and child's rate of responding to parent-provided language opportunities; "responsivity") and standardized measures (Vineland Adaptive Behavior Scales (VABS) and Autism Diagnostic Observation Schedule-2; ADOS-2). Detailed information about the implementation process (i.e., training, referral/service delivery model, uptake, satisfaction, and acceptability, and other factors related to implementation are described in a linked submission: "Community Implementation of Social ABCs"). All parents received 12 weeks of one-on-one coaching, supported by the Social ABCs parent manual. Data were collected at baseline and weeks 1, 8, 12 (and 24 when available).

Results: Parents achieved implementation fidelity at a mean rate of 68% by week 4, and 80% by week 8, with significant gains compared to baseline (both *p*'s < .001); for the sub-set who have now completed their week 24 evaluation (n = 59), fidelity remained high (*M* = 73.76%). By week 8-12, 92.6% of families had achieved the pre-established target rate of 75% fidelity. Child Responsivity increased significantly from week 1 to week 12 ($t = 13.32$, $p < .001$). ADOS-2 scores pre-versus post-intervention revealed significant decreases in symptoms in the Social Affect domain (*M* = 14.3 vs. 11.8; $t = 4.89$, $p < .001$), but not the Restricted and Repetitive Behavior domain ($p = .15$). Standard scores for the VABS Communication domain (but no other domain) increased significantly from baseline (*M* = 71.0 to 73.4; $t = 2.44$, $p = .02$).

Conclusions: Findings demonstrate the successful implementation of the Social ABCs in a large, diverse community setting. Parents learned the techniques and toddlers made gains based on video-coded indices, direct assessment, and parent-reported function. These findings support the effectiveness of parent-mediated intervention for toddlers with confirmed or suspected ASD, and highlight both the scalability and portability of the Social ABCs for implementation within a community service-delivery model.

1:42 **184.002** Indirect Effect of Impact Intervention on Expressive Communication in Infant Siblings of Children with ASD

P. Yoder[1], *W. L. Stone*[2], *C. Bush*[3] *and K. Ragsdale*[2], *(1)Department of Special Education, Vanderbilt University, Nashville, TN, (2)Psychology, University of Washington, Seattle, WA, (3)Special Education, Vanderbilt University, Nashville, TN*

Background: Infant siblings of children with ASD are at 40% risk of developing a communication disorder due to ASD or language delay. The ImPACT (Improving Parents As Communication Teachers) intervention may be one way to mitigate the risk of communication disorder. One goal of ImPACT is to teach parents to model language related to the child's focus of attention with the goal of facilitating the transition from pre-linguistic to linguistic communication. Using a weighted frequency of intentional communication enables showing growth in expressive communication during this transitional developmental period. Measuring changes in measurement contexts that differ on multiple dimensions from the treatment sessions provides a strong basis for inferring that the treatment produced generalized change.
Objectives: To test whether ImPACT's effect on weighted frequency of intentional communication is due to its effect on parents' language modeling.

Methods: We randomly assigned 53 parent-child dyads to either the ImPACT or a business-as-usual control group. See Table for participant description at study entry. Coders and examiners were blind to treatment assignment. Overall attrition was 10%; three from ImPACT, two from Control, respectively. Equivalency of groups at Time 1 was assessed on 15 relevant variables, which were controlled when indicated. There were two sites, but no site effects. Three measurement periods were separated by 3 months (pretest, immediate posttest, and 3-mo follow-up).

Parents were trained by an ImPACT-certified speech-language pathologist (SLP) or someone trained by the certified SLP. Mean percent adherence to ImPACT protocol for staff teaching parents was 91% (*SD* = 3%). Treatment sessions occur in the home. Twenty-four sessions occurred across 3 months between pre- and immediate post-tests.

Parents' language modeling (utterances that verbally mapped the child's focus of attention) was assessed at pre- and immediately post-treatment during a 15-minute parent-child free play activity that occurred in the lab. The number of 5-s intervals with parental language modeling was the putative mediator.

Weighted (nonverbal = 1 point, single word = 2 points, multiword = 3 points) frequency of intentional communication was measured at pretest and 3-mo follow-up during the Communication and Symbolic Behavior Scales (CSBS), an examiner-led structured communication sample. The CSBS used a different person, materials, activity and interaction style than that used in parent-implement ImPACT sessions, which was considered a strong test of generalization.

Results: As predicted, greater gains occurred in the ImPACT group than in the Control group for parents' language modeling ($p < .001$, $d = 1.0$) and for children's weighted frequency of intentional communication ($p = .05$; $d = .46$). As predicted, the indirect effect was significant. That is, the product of the effects of treatment on parental language modeling (the *a* path) and parental language modeling on child communication controlling for the treatment (the *b* path) had a confidence interval that did not include zero. See Figure.

Conclusions: Using ImPACT facilitated the transition from pre-linguistic to linguistic communication by increasing parents' modeling of language. Ultimately, ImPACT may be one method to mitigate the risk of communication disorder in infant siblings of children with ASD.

1:54 **184.003** A Multi-Component Communication Intervention for Preverbal Preschoolers with Autism: Outcomes from an RCT

E. Fuller[1], *L. H. Hampton*[2] *and A. P. Kaiser*[1], *(1)Special Education, Vanderbilt University, Nashville, TN, (2)Northwestern University, Evanston, IL*

Background: Half of children with autism at age 33-months are preverbal (Eaves & Ho, 2004) and are at high risk for remaining in the 30% of children with autism who are persistently minimally verbal (DeMeyer et al., 1973, Tager-Flusberg & Kasari, 2013). Targeting foundational skills for spoken language in the preverbal ASD population, including imitation, receptive language, and joint attention (Weismer, Lord, & Esler, 2010, Paul, Campbell, Gilbert, & Tsiouri, 2013), may be crucial for reducing the prevalence of children who remain minimally verbal. The purpose of this study was to test a multi-component intervention that combined direct teaching of foundational skills with a naturalistic communication intervention, parent training, and a speech generating device (SGD) for preverbal preschoolers with ASD.
Objectives:

- Do children receiving a multi-component communication intervention show greater improvements in communication skills compared to children in a control group?
- Do caregivers who are trained in the intervention use more language facilitative strategies than parents who are in a control group?

Methods: Preschool-aged children with autism (N= 68; mean age= 43 months) who used fewer than 20 words in a naturalistic language sample (NLS) were randomly assigned to receive a multi-component communication intervention or to the control group. Both of the groups received an SGD programmed specifically based on the child's communicative abilities for use for the duration of the study.

The intervention group received 36 60-minute sessions comprised of four evidenced-based components: (a) direct teaching of foundational skills, (b) training to use an SGD; (c) a naturalistic communication intervention (J-EMT); (d) parent training in communication-support strategies.

Children and their caregivers were assessed before intervention, immediately after the 4-month intervention, and 4-months following intervention. Language and communication was assessed on: the Preschool Language Scales (PLS, Zimmerman), the Early Social Communication Scales (ESCS; Mundy, 2003), a 20-minute NLS with an assessor blind to group assignment, and a 10-minute caregiver-child interaction (CCX). The number of socially communicative utterances (SCU) was coded from the language sample and CCX. Parent use of strategies was coded from the CCX.

Results: Children in the intervention group made greater gains than children in the control group across all communication outcomes, however the significant differences between groups were observed only for the number of initiations of joint attention at posttest (b=0.644, SE=0.270 p=0.017) and SCU in the CCX at follow-up (b=0.838 SE=.425, p=.049). Object interest and frequency of escape behaviors moderated the effects of intervention on initiating joint attention, such that children in the intervention group with lower frequency play behaviors and higher frequency escape behaviors at pretest demonstrated significantly more joint attention at posttest. Caregivers in the intervention group used significantly more language facilitation strategies following intervention.

Conclusions: A brief multi-component communication intervention improved joint attention skills in preverbal children with ASD immediately

following intervention and increased social communicative utterances with their trained caregivers 4 months after intervention. Future research should examine mediators of treatment to better identify how this treatment approach is effective. Longer term follow-up of children's communication outcomes is needed.

2:06 **184.004** Barriers to Participation in a Parent-Mediated Intervention for 12-Month-Old Infant Siblings of Children with ASD

A. Trumbull[1], *J. Bradshaw*[2], *C. A. Saulnier*[3,4], *J. L. Stapel-Wax*[5], *A. Klin*[6] *and A. Wetherby*[7], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)Department of Psychology, University of South Carolina, Columbia, SC, (3)Neurodevelopmental Assessment & Consulting Services, Decatur, GA, (4)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, (5)Emory University School of Medicine, Atl, GA, (6)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (7)Florida State University Autism Institute, Tallahassee, FL*

Background: As more evidence emerges that optimal developmental outcomes for individuals with autism spectrum disorder (ASD) are associated with the earliest possible onset of intervention in the infant and toddler years (Rogers et al., 2012), it is essential to identify barriers to parent participation in very early intervention programs. Despite the strong evidence for parent-mediated early interventions for ASD (e.g., Bradshaw, Koegel, & Koegel, 2017; Carter, et al., 2011), caregivers may sometimes elect not to take advantage of treatment services that are available to them.

Objectives: The current study aims to describe barriers to enrollment into an early parent-mediated intervention trial as part of a longitudinal investigation of infant siblings of children with ASD.

Methods: As part of a prospective longitudinal design, 23112-month-old infants were given an assessment of social-communication skills (Communication Symbolic Behavior Scales – Behavior Sample) and autism symptomology (Home and Clinic Systematic Observation of Red Flags for ASD (SORF) and ESAC). Infants who exhibited early signs of ASD and delays in social-communication during the 12-month assessment based on the study's eligibility criteria (i.e., scoring above the screening threshold for 2 out of the four measures) (N=47) were offered enrollment into a randomized controlled trial of a parent-mediated early intervention for ASD. Of these 47 infants, 29 (62%) caregivers enrolled into the treatment study and 18 caregivers (38%) declined treatment. We compare infant clinical characteristics, family demographics, and older sibling autism symptom severity across families who agreed to treatment and those who did not in an effort to identify those variables that may serve as barriers to accessing caregiver-mediated intervention.

Results: Results revealed significant differences in several demographic characteristics of the caregivers who elected not to enroll in the treatment study. Specifically, participants who declined treatment were characterized by greater maternal full-time employment ($p < .01$), higher level of education ($p < .05$), and living further from the clinic ($p < .01$). Child birth order also had an impact on enrollment statistics, with families who had more than two children (including the infant and older child with ASD) being less likely to enroll than families with only two children. Surprisingly, there were no significant differences in clinical presentation across infants who enrolled into treatment compared to those who did not.

Conclusions: In summary, findings highlight a number of barriers to enrollment into early intervention strategies for children at high risk for autism spectrum disorder, most of which are related to caregiver resources. In this study, one component of the treatment required parents to come to the clinic once per week with their infant, potentially leading to families with limited time (full-time work and/or more than two children) to decline participation. These data suggest that in-home treatment for young siblings of children with ASD may be critical in broad dissemination of infant interventions. Knowledge of such barriers by professionals may contribute to the use of additional techniques for increasing enrollment into important intervention strategies and improving outcomes for young children with social communication deficits.

Oral Session - 9B

2:30 **185.001** Does Adding Mindfulness Based Stress Reduction to Early Intervention Improve Caregiver Functioning?: A Randomized Controlled Trial

A. S. Weitlauf[1], *N. Broderick*[2], *A. Stainbrook*[3], *J. L. Taylor*[3], *C. G. Herrington*[2], *A. Nicholson*[4], *M. Santulli*[5], *E. Dykens*[6], *P. Juárez*[2] *and Z. Warren*[2], *(1)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Nashville, TN, (4)Vanderbilt University, Pleasant View, TN, (5)Department of Pediatrics, Vanderbilt University Medical Center/Vanderbilt Kennedy Center, Nashville, TN, (6)Vanderbilt University, Nashville, TN*

Background: Systems of care increasingly emphasize parent-delivered early intervention for young children with autism spectrum disorder (ASD). Multiple studies have documented high levels of psychological distress within parents of children on the autism spectrum. However, few studies have examined how to support caregiver wellbeing directly as part of early behavioral intervention.

Objectives: This randomized controlled trial compared caregivers who completed 12 sessions of the Parent-implemented Early Start Denver Model (P-ESDM; n = 31) to caregivers who completed P-ESDM in addition to six concurrent individual sessions of Mindfulness Based Stress Reduction (MBSR; n = 30).

Methods: Caregivers (53 mothers, 8 fathers) and their child with ASD (mean age = 2.37 years, sd = .46; mean ADOS-2 Calibrated Severity Score = 8.11, sd = 1.63) participated in 12 weekly P-ESDM sessions. Half of caregivers were randomized to also receive six individual MBSR sessions. Caregivers completed the Beck Depression Inventory, Beck Anxiety Inventory, Parenting Stress Index, and Five Facet Mindfulness Questionnaire at baseline, 6 weeks, 12 weeks (treatment end) and 1-, 3-, and 6-months post treatment. Groups were similar at baseline on all outcome variables and demographic characteristics (caregiver sex, annual income, caregiver educational level, racial/ethnic background). Attrition was similar across groups and caregiver demographics.

Results: Multilevel models with discontinuous slopes (active treatment slope, change in slope post-treatment) were used to test for group

differences in change in outcomes over time. When considering the whole sample, resulting coefficients [standard errors] revealed significant (p < .001) average improvement during active treatment in all sub-domains of parent stress: parental distress (-1.32 [.28]), parent-child dysfunctional interaction (-1.18 [.26]), and difficult child (-.90 [.23]). These scores all significantly increased again post-treatment (ps < .01). During treatment, overall scores also decreased for depression (-.65 [.23]; p < .05) and anxiety (-.81 [.30]; p < .05). Depression scores significantly increased again post-treatment (.76 [.26]; p <.01), but improvements in anxiety were maintained (no significant change). Whole group analyses did not reveal changes in mindfulness. Considering groups separately, caregivers who received MBSR had greater improvements in parental distress (-1.69 [.47]; p < .01) and parent-child dysfunctional interactions (-1.12 [.45]; p < .05). Parental distress increased again post-treatment (1.46 [.69]; p < .05). Caregivers who received MBSR also improved in mindfulness (2.83 [1.36]; p < .05), whereas caregivers in only P-ESDM reported lower mindfulness scores over time. Treatment group did not significantly predict slopes (during active treatment or post-treatment) for depression or anxiety. Differential response trajectories emerged for male caregivers and caregivers of younger children, but no significant effects were found for child autism severity nor caregiver educational attainment.

Conclusions: Providing MBSR training as part of parent-mediated early behavioral intervention for very young, newly diagnosed children resulted in greater improvements in caregiver-reported levels of parenting stress relative to behavioral intervention alone. Results suggest that systems of care can offer caregivers manualized, low intensity training in stress reduction strategies that may have long-term impacts on how they interact with their children.

2:42 **185.002** Quality Matters: Application of Intervention Fidelity Benchmarks to Community Paraprofessional Delivered Social Communication Intervention for Toddlers with Autism

S. Y. Shire[1], *W. I. Shih*[2], *S. Bracaglia*[3], *M. Kodjoe*[3] *and C. Kasari*[2], *(1)University of Oregon, Eugene, OR, (2)University of California, Los Angeles, Los Angeles, CA, (3)New York Center for Child Development, New York, NY*

Background: Community Partnered Participatory Research can support the adoption of research-based practices in real world settings. The transfer of intervention protocols into community practice can be challenging, but deployment trials have demonstrated success sharing strategies with caregivers (Green et al., 2010; Kasari et al., 2014) and community educators (Chang et al., 2016). Although achieving 80% fidelity is a typical research standard, it is not as clear what constitutes "good enough" fidelity by which a minimum standard for program implementation may lead to empirical change in children's target outcomes.

Objectives: To explore whether implementation benchmarks previously published (Shire, Shih, & Kasari, 2018) for caregiver-mediated Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2008; 2014) intervention would also differentiate children's outcomes when: (a) delivered by paraprofessional teaching assistants' (TAs) and (b) when adapted for small group instruction (referred to as jasPEER).

Methods: Forty-eight TAs and 113 toddlers (mean age=32.28 months) across four classrooms were randomized to JASPER with a peer (jasPEER) or one-to-one JASPER waitlist control. Children had received outside diagnoses of autism (*n*=1 with Down Syndrome). All but two TAs, and two children were members of an ethnic minority group.

Intervention. Significant effects of JASPER over treatment as usual on joint engagement, joint attention gestures, play skills, and language were demonstrated with this center in a prior trial (Shire et al., 2018). Building upon TAs' knowledge of one-to-one JASPER, they were provided with two weeks of in-vivo training and ongoing video feedback from the research team to learn the jasPEER adaptation. Children in waitlist classrooms received JASPER for 30 minutes a day for 11 weeks, while children in immediate jasPEER received the adapted peer version during this time.

Measures. Ten-minute video recorded TA-child interactions at entry, exit, and one month follow up were coded for children's play level (number of 1-minute intervals in simple, combination, pre-symbolic, and symbolic play) and TAs' implementation (total strategy implementation score).

Results: Examining TA's implementation fidelity at exit, 34 children received sessions at 75% or greater fidelity ("high fidelity"). The number of children receiving high fidelity sessions did not significantly differ between JASPER and jasPEER. Significant growth in children's pre-symbolic play (t(244)=2.39, p=0.017) was found for children in the high fidelity group, while gains were not significant for children in the lower fidelity group. Concurrent to this shift to higher level play was a significant decrease in combination play for the high fidelity group only (t(244)=-2.59, p=0.010). Simple and symbolic play occurred too infrequently to model.

Conclusions: Findings replicate differential outcomes for children when either intervention model was delivered with at least 75% implementation fidelity than below 75%. Considering the age and developmental heterogeneity of this diverse community sample of toddlers with ASD, gains in pre-symbolic play where children move beyond combining objects to extend acts to self and agents are clinically significant.

2:54 **185.003** A Multi-Site Randomized Control Trial of Family Navigation's Effect on Diagnostic Ascertainment Among Children at Risk for Autism: A Dbpnet Study

E. Feinberg[1,2], ***S. Broder-Fingert***[2,3], *A. Bennett*[4], *C. Weitzman*[5], *A. Chu*[1], *J. Eilenberg*[6], *M. Abraham*[4], *M. Credle*[5], *H. Cabral*[1], *M. Augustyn*[2,3], *G. Patts*[1], *J. Guevara*[4], *A. Fenick*[5] *and N. Blum*[4], *(1)Boston University School of Public Health, Boston, MA, (2)Boston University School of Medicine, Boston, MA, (3)Boston Medical Center, Boston, MA, (4)The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Yale University, New Haven, CT, (6)Boston University, Boston, MA*

Background: Significant racial, ethnic, and socioeconomic disparities exist in access to diagnostic and evidence-based treatment services for children with autism spectrum disorder (ASD). Barriers to timely ASD diagnostic and treatment services can result from various factors including the availability of services, patient-provider miscommunication, parental stress, and culturally biased care. Family navigation (FN) is a care management strategy designed to reduce disparities in access to care, through provision of intensive, individually tailored, care coordination and family support.

Objectives: The purpose of this study was to test the effectiveness of FN to reduce time to diagnosis and increase access to treatment services for children at risk for ASD.

Methods: In this large, multi-site randomized comparative effectiveness trial, families of children at risk for ASD were recruited from urban clinics in Massachusetts (*n* = 6 clinics), Connecticut (*n* = 2), and Pennsylvania (*n* = 2). Eligible children were between the ages of 15-27 months (*n* = 250), who screened positive for ASD at a primary care visit. Families were randomized to receive either FN or enhanced usual care (eUC). FN families worked with a bilingual, bicultural navigator trained in motivational interviewing, who met with families in the community, conducted outreach to

service agencies as needed, and reminded families about upcoming appointments. eUC families received access to a clinic-based care manager, who addressed parent and provider concerns but did not actively reach out to families. Families received FN or eUC throughout their child's developmental assessment and for 100 days post-diagnosis.

Results: The trial successfully enrolled the desired target population: young, low-income, racially diverse children. The average age of enrolled children was 21.7 months. 12.4% of children in the study were white, 54.8% were black/African-American, 6.4% were Asian, and 5.2% were mixed-race. 29.0% were Hispanic and 82.4% were covered by public insurance. Children scored an average of 8.6 (SD=3.1) on the Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (MCHAT-R/F) at time of enrollment in the study, with no significant differences reported between the FN or eUC groups. Approximately 60% of all children received an ASD diagnosis, with no significant differences between children who received FN versus eUC. By 90 days after enrollment, significantly more children in the FN group had achieved diagnostic resolution than those in the eUC group (55% versus 41%, p=0.022). By 1-year after enrollment, children who received FN had more than twice the odds of reaching diagnostic resolution as compared to children who received eUC, 86.6% vs 74.8%, respectively (Odds Ratio, 95% Confidence Interval, p-value; 2.18, 1.14-4.19, 0.019).

Conclusions: This study supports the effectiveness of FN to improve rates of ASD diagnostic resolution among urban minority, low-income children who are detected as "at-risk" for ASD in primary care. Because a formal medical ASD diagnosis is required in the majority of states to access early-intensive evidence-based ASD services, these findings support the use of FN to assure timely access to diagnosis, and ultimately services, for low-income, urban children.

3:06 **185.004** Screening and Linkage to Services for Autism (SaLSA): Randomized Controlled Trial of Family Navigation

C. DiGuiseppi[1], *S. Rosenberg*[2], *M. Tomcho*[3], *K. Colborn*[2], *K. Hightshoe*[2], *S. Gutiérrez-Raghunath*[3], *J. Cordova*[4], *J. Litfin*[5] *and C. Robinson Rosenberg*[6], *(1)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Denver Health and Hospitals Authority, Denver, CO, (4)Bright Futures LLC, Denver, CO, (5)Rocky Mountain Human Services, Denver, CO, (6)University of Colorado / JFK Partners, Aurora, CO*

Background: Autism spectrum disorder (ASD) is under-diagnosed and under-treated in young children, particularly minority and disadvantaged children. Even with routine ASD screening, many screen-positive children fail to receive appropriate referral, evaluation, or services. Patient navigation, originally developed to address healthcare disparities, could facilitate referral, evaluation, and linkage to early intervention (EI) services.

Objectives: Evaluate the effect of family navigation for children with positive ASD screening on referral, evaluation and linkage to EI services.

Methods: Using a randomized controlled trial design, children aged 16-30 months seen for well care in a community health center network, who had an initial score ≥3 on the Modified Checklist for Autism in Toddlers-Revised with Follow-Up (M-CHAT-R/F), were randomly allocated to family navigation (if needed) or usual care. A bilingual, trained family navigator (FN) contacted intervention-group families if referral for evaluation was indicated (whether or not a referral had occurred) based on the M-CHAT-R/F: initial score ≥8 or initial score 3-7 with Follow-Up score ≥2. The FN offered care coordination, education, coaching, translation/interpretation, and psychosocial and practical support. The FN also assisted families of children with initial scores of 3-7 to obtain the indicated Follow-Up when not done, and offered navigation if the Follow-Up score was ≥2. Outcome data were obtained from electronic health and EI records. Generalized linear models with log links were used to compare outcomes between groups based on intention-to-treat.

Results: Families of 275 children were randomized to intervention (n=142) or control (n=133). Children were 62% male, 61% Hispanic, 44% non-White, and 93% insured by Medicaid (for low-income families); 30% lived in non-English-speaking households. Of intervention-group families, 52 were eligible for family navigation based on the need for referral; 22 families (42%) were successfully contacted and accepted FN assistance. Intervention children were significantly more likely than controls to complete the full two-step M-CHAT-R/F (68% vs. 54%, RR=1.25, 95%CI: 1.03, 1.52, p=0.02). There were no significant between-group differences in their likelihood of being referred for EI eligibility determination (45% vs. 45%, p=0.99), completing an evaluation for EI eligibility (25% vs. 23%, p=0.69), or initiating services (20% vs. 20%, p=0.86). However, intervention children were nearly three times as likely to undergo a diagnostic evaluation for ASD (11% vs 4%, RR=2.81 [1.05, 7.52], p=0.04). Twelve (8%) intervention and five (4%) control children were diagnosed with ASD (RR=2.25 [0.81, 6.21], p=0.12). Results were similar when limited to children who had received a referral for eligibility determination.

Conclusions: With family navigator assistance, young, minority, low-income children at risk for ASD were more likely to complete the full two-step M-CHAT-R/F and an ASD diagnostic evaluation. However, family navigation did not increase referral by healthcare providers, evaluation for EI eligibility or initiation of EI services. In both study groups, large proportions of referred children failed to complete evaluations for EI eligibility and for ASD. Even with trained, bilingual, Latina navigators, engaging families was difficult. Research is needed to identify effective methods to improve uptake of family navigation and to increase evaluation after a positive ASD screen in low-income, minority families.

Education
186 - Education
1:30 PM - 2:25 PM - Room: 524

1:30 **186.001** Profiles and Predictors of School Functioning Among Children with Autism Spectrum Disorders

A. Zaidman-Zait[1], *P. Mirenda*[2], *P. Szatmari*[3], *I. M. Smith*[4], *J. Volden*[5], *T. Vaillancourt*[6], *C. Waddell*[7], *L. Zwaigenbaum*[5], *T. Bennett*[8], *E. Duku*[9], *S. Georgiades*[9], *W. J. Ungar*[10] *and C. M. Kerns*[11], *(1)Tel-Aviv University, Tel-Aviv, Israel, (2)University of British Columbia, Vancouver, BC, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (5)University of Alberta, Edmonton, AB, Canada, (6)University of Ottawa, Ottawa, ON, Canada, (7)Simon Fraser University, Vancouver, BC, Canada, (8)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (9)McMaster University, Hamilton, ON, Canada, (10)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (11)Department of Psychology, University of British Columbia, Vancouver, BC, Canada*

Background: Children with ASD demonstrate high variability in academic achievement; for many, academic achievement is lower than would be expected based on their IQ (Estes et al. 2011; Jones et al. 2009; Keen et al. 2015; Wei et al. 2013). In addition, children with ASD are less likely to enjoy or cooperate at school compared to typically developing peers (Jahromi et al. 2013), and often experience challenges in social interactions and relationships with classmates. Studies suggest that multiple competencies (both academic and social) work jointly to facilitate or undermine children's adjustment; thus, competencies should be examined by considering functioning across domains. There is limited knowledge regarding early predictors of educational outcomes among children with ASD.

Objectives: This study examined (1) patterns of academic and social school functioning among 10-11 year-old children with ASD; and (2) early behavioral and social communication indicators, measured around age 3, as predictors of children's school functioning profile membership.

Methods: The sample included 178 children from the Canadian *Pathways in ASD* study. Latent profile analysis (Vermunt & Magidson, 2013) was used to identify and describe profiles of children's school functioning (academic and social outcomes) when children were around 10-11 years old. Academic functioning outcomes included the composite standard score of the Wechsler Individual Achievement Test II (WIAT--II-A; Wechsler, 2001) and teacher reports of academic performance and school engagement (Teacher Report Form, Achenbach, 1991). Social functioning included parents' and teachers' report on adaptive socialization skills (VABS-II; Sparrow et al., 2005) and both pragmatic competence and children's social relations (CCC-2; Bishop, 1998). Early behavioral and social communication indicators at age 3 were examined as predictors of profile membership approximately 6 years later. Early predictors included autism severity (ADOS; Lord et al. 2000), behavior problems (Aberrant Behavior Checklist; Aman et al., 1985), imitation ability (Multidimensional Imitation Assessment; Lowe-Pearce & Smith, 2005), and initiating and responding to joint attention (Early Social Communication Scales; Mundy et al., 2007).

Results: A four-profile model of children's school functioning showed the best fit and was also the most parsimonious (Figure 1). Profile 1 (30%) was characterized by the highest scores on school functioning across both academic and social outcomes. Profile 2 (24%) had low outcomes on academic achievement and performance, with school engagement and social outcomes that were in the average range for the *Pathways* sample in this analysis. Profile 3 (21%) displayed above average academic achievement and performance, with social outcomes (i.e., pragmatic skills and social relations) that were relatively low. Finally, Profile 4 (24%) had the lowest level of school functioning across both academic and social outcomes. Three early behavioral and social communication indicators measured around age 3 significantly predicted profile membership; these included behavior problems (Wald = 15.07, $p < .01$), imitation (Wald=34.02, $p < .001$); and responding to joint attention (Wald = 25.13, $p < .001$).

Conclusions: School functioning is complex and variable in elementary-aged children with ASD. Professionals providing early intervention should focus on enhancing early social communication skills that may help to enhance future school functioning.

1:42 **186.002** Classroom Mathematical Learning Opportunities for Students with Autism Spectrum Disorder

N. Sparapani[1], *N. S. Tseng*[2], *T. S. Wood*[3], *S. Karimi*[1], *K. Singh*[2] *and J. Rodriguez*[1], *(1)School of Education, University of California, Davis, Davis, CA, (2)Teacher Education, University of California, Davis, CA, (3)School of Education, University of California, Irvine, Irvine, CA*

Background: Academic achievement is critical for educational and lifelong success (NICHD, 2000). Rich educational experiences have been associated with positive educational outcomes (Hiebert & Grouws, 2007), mental and physical well-being (Adams, 2002), and opportunities for employment (Duncan et al., 2007). Very few studies have examined the educational opportunities that students with Autism Spectrum Disorder (ASD) experience during mathematical lessons and how their experiences relate to participation and learning.

Objectives: The purpose of this study is to evaluate the nature and variability of mathematics instruction provided in preschool–3rd grade classrooms serving students with ASD. We utilized systematic observational methods in order to examine the amount and type of mathematics instruction that students receive as well as the degree of student participation and variability in teachers' language.

Methods: Participants included (n = 60) preschool–3rd grade students with ASD and their teachers (n = 36) who were recruited for a longitudinal study evaluating the efficacy of a classroom-based intervention and video-recorded in their classrooms at the beginning of the school year. We identified types of mathematics tasks students were presented with within the lesson across four categories:1) tasks focusing on recall and rote memorization (e.g., identifying numbers and reciting multiplication facts), 2) procedural tasks that highlight the learning of standard algorithms (e.g., writing out steps of addition), 3) tasks that tap into conceptual knowledge and content building, and 4) tasks that require problem-solving/mathematical reasoning. Next, trained observers coded student participation (amount of time that students attended to and appropriately utilized manipulatives and materials) as well as teachers' use of close-ended, open-ended, responsive, and directive language using Noldus Observer® Video-Pro Software. Interrater agreement between observers ranged between 80%–91%.

Results: Preliminary findings from 15 students and their teachers (n = 10) across 21 mathematics tasks indicated that students spent very little time engaged in mathematics instruction overall, with an average of 66% (SD = 18.70) of the lesson dedicated to mathematical content. A large percentage of the lesson focused on non-instructional activities, such as redirecting student behavior and attention or transitioning between materials. During mathematics tasks (M = 5:17 minutes, SD = 3:57), teachers most frequently provided opportunities for students to practice math facts (M = 57% of the tasks) and rehearse procedural steps of mathematical problems (M = 38%). Students spent very limited time on average (M = 00:09 seconds; SD = 00:06) interacting with relevant materials or looking at people. Finally, teachers used more directive language (e.g., "point to the number 5"; M = 43.00, SD = 38.60) and instructional comments (e.g., "this is the number 5"; M = 20.43, SD = 18.23) than all other language categories.

Conclusions: These data may have important implications for understanding the quality of instructional practices for students with ASD within mathematics lessons. Findings suggest that students with ASD may receive less than substantive learning opportunities in mathematics, which may have important educational consequences, and highlight salient instructional talk that might lead to improved participation in learning opportunities and deeper mathematical understandings.

1:54 **186.003** The Use of Recommended Practices for Children with ASD in Public Preschool and Elementary Schools

A. S. Nahmias[1], *J. Suhrheinrich*[2], *S. R. Rieth*[2] *and A. C. Stahmer*[3], *(1)MIND Institute, UC Davis Medical Center, Sacramento, CA, (2)San Diego State University, San Diego, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Outcomes for children with ASD in community service systems do not match those demonstrated in controlled trials (Nahmias et al., under review). It is important to understand what factors support best outcomes in usual care. As the educational system is the primary service children for children with ASD (Brookman-Frazee et al., 2009), studying intervention as it is delivered in the public education system can provide important insights which recommended practices have the potential to be most effective, given the resources available (Stahmer & Aarons, 2009). Evaluation of classroom quality measures that are specific to the instructional needs of students with ASD may specifically inform this goal.
Objectives:

- To examine predictors of use of recommended practices for children with ASD based on teacher and classrooms characteristics, and
- To examine the association of recommended practice use with student cognitive gains.

Methods:

Participants (45 teachers, 95.7% female; 68 students, 86.8% male) were part of the control arm of a randomized trial of an educational intervention for students with ASD in public preschool and elementary schools (mean student age = 68.0 months, *SD* = 22.1). Observers rated implementation of recommended practices for children with ASD using the Educational Program Review (EPR) in four classroom types: Mild/Moderate, Moderate/Severe, Autism, and Inclusion. Based on observation and teacher interview, raters coded skill indicators of Teaming, Classroom Structure, Classroom Environment, Curriculum and Instruction, Social/Peer Relationships, Challenging Behaviors Management, and Positive Instructional Climate. Teachers completed a demographic questionnaire. Children were assessed at the beginning and end of the school year with the same standardized cognitive assessment (either the Mullen Scale of Early Learning or the Differential Abilities Scales). Analyses included: (1) ANOVAs comparing EPR scores among classroom types, (2) Pearson correlations and ANOVAs examining associations between teacher characteristics and EPR scores, (3) a paired t-test assessing student cognitive gains over the school year, and (4) Generalized Estimating Equations examining the association between EPR domain scores on cognitive change scores.

Results:

EPR scores did not differ by classroom type, teacher years of experience in special education or with ASD, or teacher reported job-related stress (all *p*s > .08). Teachers with Bachelor's degrees had higher positive Instructional Climate scores than those with Master's degrees. Teachers with higher job satisfaction had higher Classroom Structure, Classroom Environment, Curriculum, and Social/Peer relationships scores (all *p*s < .03). Student cognitive scores increased by 4.7 points on average over the school year ($t(67) = 5.3$, $p < .0001$). Better implementation of recommended practices for Classroom Environment (e.g., low student-teacher ratio, use of natural/direct reinforcement, use of clear and meaningful instructions) was the unique significant predictor associated with cognitive gains ($B = 4.28$, $p = .03$) in adjusted analyses.

Conclusions:

Unlike in our previous research (Nahmias, 2017), the use of recommended practices for children with ASD did not differ by classroom type. The implementation of recommended practices for the classroom environment were particularly important for cognitive gains in students receiving publicly funded special education and offer strategies that may be beneficial for teachers in community settings to emulate.

2:06 **186.004** Changes in US Special Education Autism Eligibility Rates from 2010 to 2016

L. J. Dilly[1], *N. Hendrix*[2], *J. Salim*[3] *and C. McCracken*[4], *(1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Emory University School of Medicene, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (4)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA*

Background: Current U.S. estimates of the prevalence of autism spectrum disorders (ASD) are 1 in 59 (i.e., 170/10,000) children (Baio et al., 2018). Public schools provide necessary services for children with ASD; however, many children with a medical diagnosis of ASD do not have corresponding special education eligibility in ASD (Pinborough-Zimmerman et al., 2012; Rubenstein et al., 2018). Further, ASD identification rates vary across racial groups, with some evidence that African American children are identified at lower rates and older ages than Caucasian children (Baio et al., 2018; Locke et al., 2017).
Objectives: We evaluated changes in ASD special education eligibility rates in the U.S. between 2010 and 2016. Patterns of ASD eligibility rates in relation to eligibility rates for speech and language impairments (SLI) and developmental delays (DD) were considered, as well as patterns across age and race (i.e., Caucasian, African American).

Methods: Publicly accessible U.S. Department of Education special education data from the 2010-11 and 2016-17 school years were used with corresponding years of U.S. Census Bureau State Datasets. Data from 48 states, excluding Iowa (a non-categorical eligibility system) and Wyoming (missing data), were analyzed. These analyses used overall numbers of children in special education and those with primary eligibilities in ASD, DD, or SLI.

Results: Between 2010 and 2016, the rate of ASD eligibility per 10,000 children increased from 40 to 56 for children ages 3 to 5, 81 to 105 for children 6 to 11, and 57 to 87 for children 12 to 18. The proportion of children eligible under ASD compared to all children eligible for special education increased between 1.7% and 3.3% across age ranges. Within the youngest age range (3-5 yrs) there was no correlation between ASD and DD rates ($r = -0.08$, $p = 0.62$) nor between ASD and SLI rates ($r = 0.11$, $p = 0.47$). The ratio of Caucasian to African American children ages 3 to 5 with eligibilities in the areas of ASD, DD, and SLI were 0.88 ($M = 0.90$, $SD = 0.3$), 0.87 ($M = 0.91$, $SD = 0.3$), and 1.42 ($M = 1.77$, $SD = 1.1$), respectively.

Conclusions: Special education ASD eligibility rates are one-third to two-thirds lower than ASD prevalence rates, though there is a trend toward greater identification between the years 2010 and 2016. Low rates of ASD eligibility rates for young children are consistent with past research but are troubling given the importance of early intervention (Baio et al., 2018; Zwaigenbaum et al., 2015). Given the lack of correlations between rates of ASD eligibility and rates of SLI and DD eligibility, we do not have evidence to suggest young children may be identified as having SLI or DD rather than ASD. However, differences in eligibilities were present across racial groups in young children. Specifically, Caucasian children were more likely to be identified with SLI, while African American children were more likely to be identified with ASD and DD, a finding which will be discussed in the context of literature.

Oral Session - 10B
Communication and Language
187 - Communication and Language
2:30 PM - 3:25 PM - Room: 524

2:30 **187.001** Parental Linguistic Alignment to Their Children Facilitates Language Acquisition, with Syntactic Alignment Being Particularly Relevant for Children with ASD

R. Fusaroli[1], *E. Weed*[1], *D. A. Fein*[2] *and L. R. Naigles*[2], *(1)Aarhus University, Aarhus, Denmark, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Parent language is a crucial factor in language acquisition in children with ASD and TD children alike, but its role as a scaffold for the child's linguistic production on a turn by turn basis is under-investigated. Here we focus on interactive alignment, that is, the tendency to re-use the child's lexical ("mommy, give me the *giraffe*", "is that a *giraffe*?"), syntactic ("*the giraffe has fallen*", "yes and *the elephant has gone* down to help her") and semantic (topic maintenance) choices. Besides supporting common ground and rapport, interactive alignment might facilitate language development by providing a rewarding parental response to children's productions, as well as contextualized linguistic input via elaboration.

Objectives: We investigate whether i) parental alignment to their children might affect language development beyond more traditional measures of parental input (total and unique words, Mean Length of Utterance, or MLU), and ii) this is modulated by the cognitive and clinical features of the children.

Methods: We analyzed spontaneous speech in 67 parent-child dyads from a longitudinal corpus (6 visits over 2 years), consisting of 30 minutes of play activities. We included 32 children diagnosed with ASD (mean age at recruitment: 32.76m) and 35 linguistically matched TD children (mean age at recruitment: 20.27m). Lexical alignment was based on lemmatized words, syntactic alignment on 2-grams of part-of-speech-tags, and semantic alignment on Word2Vec representations of the corpus. Alignment was calculated as cosine similarity between successive conversational turns (parent following child). To assess the effects of alignment at visit N on language learning at visit N+1, we relied on the best multilevel Poisson (total and unique words) and loglinear (MLU) models from our previous study on the role of parental input (Fusaroli et al 2019), and evaluated by Leave-One-Out-Information-Criteria whether including parental alignment improved these models.

Results: The full findings are presented in the accompanying table. The child's later MLU, unique and total words were positively affected by lexical and syntactic alignment. Parents' semantic alignment positively affected total amount of words, but negatively the number of unique words. Further, the effects of alignment were modulated by the children's features, in that children with lower previous production showed stronger effects of parental alignment on their own word use, compared with children with higher scores. Diagnosis provided independent modulation, in that children with ASD showed weaker effects on their own word use of parental lexical alignment, but stronger effects of syntactic alignment, than TD children. Finally, regardless of diagnosis, children exposed to less complex parental input (lower MLU) seemed to be more affected by the levels of parental lexical and syntactic alignment in their future word use, than those exposed to higher MLU.

Conclusions: Parental alignment differentially affected child language development. Parental lexical and syntactic alignment had positive effects on children's word types, tokens, and MLU; however, child features only modulated word use. Specifically, children with poorer production and less complex linguistic input benefited more from parental alignment of their own speech, and children with ASD in particular benefited from higher syntactic alignment.

2:42 **187.002** Reciprocal Influences between Child and Parent Language in Dyads Involving High- and Low-Risk Infants for Autism

ABSTRACT WITHDRAWN

Background:
The important role of parental linguistic input in children's language learning has been well documented in typical and atypical development (Bang & Nadig, 2015; Rowe, 2012). Yet, less research has explored how infants may impact parent language and shape their own environment (Fusaroli et al., 2019).

Objectives:

We conducted a longitudinal investigation of (1) infant language production; (2) parent language production; and (3) reciprocal associations between infant and parent language measures in dyads involving infants at high and low familial risk for autism spectrum disorder (ASD) at 12, 18, and 24 months.

Methods:

Eighty-nine mother-infant dyads were videotaped in the lab during a 10-minute interaction at 12, 18, and 24 months. Infants' and parents' language from each session was transcribed and analyzed for quantity and quality. The total number of words (word tokens) served as the measure of quantity. The total number of different words (word types) and linguistic complexity (mean length of utterance; MLU) served as the measures of quality. Infants' ASD outcomes were determined using Autism Diagnostic Observation Schedule (Lord et al., 2000) and clinical judgment at 18-36 months. Based on their risk and ASD outcomes, infants were classified into three groups: high-risk infants diagnosed with ASD (HRA+), high-risk infants not diagnosed (HRA-), and low-risk comparison infants not diagnosed (LRC).

Results:

(1) There was no significant group difference in infant language measures at 12 months. However, HRA+ infants produced significantly fewer word tokens than LRC infants at 18 months (z= -2.40, p= .02) and 24 months (z = -2.64, p= .01). Also, HRA+ infants produced significantly fewer word types than HRA- (z= -2.00; p = .05) and LRC infants (z= -2.65, p= .01) at 24 months, displaying lower quantity and quality of talk beginning within the second year of life.

(2)There was no significant group difference in parent language measures at 12 months. While there was no significant group difference in quantity, parents' talk significantly differed in quality at 18 and 24 months. At 18 months, HRA+ mothers produced significantly fewer word types than HRA- (z= -2.46, p= .01) and LRC mothers (z= -3.14, p< .01); HRA+ and HRA- mothers produced significantly shorter MLU than LRC mothers (z=

-3.96, $p < .001$; $z = -2.32$, $p = .02$, respectively). At 24 months, HRA+ and HRA- mothers produced shorter MLU than LRC mothers ($z = -2.44$, $p = .01$; $z = -2.82$, $p < .01$, respectively).

(3) When examining the reciprocal effects of parent language on child language, we found that 18-month parent MLU was a significant, positive predictor of 24-month child MLU, when controlling for child ASD risk, sex, earlier MLU, and parent education. When examining the effects of child on parent language, child word types at 12 months was a significant, positive predictor of parent MLU at 24 months, controlling for the covariates.

Conclusions:

High- and low-risk infants may shape their own linguistic environment over time, with their parents modulating linguistic input based on infant language.

2:42 **187.003** The Effects of Parent Sentence Diversity Input on Grammatical Development in Toddlers with ASD in Early Intervention Programs

C. B. Klein[1], *H. R. Thomas*[1], *J. Boucher*[2], *D. Pozzuoli*[2], *C. Lord*[3] *and S. H. Kim*[4], *(1)Psychiatry, Weill Cornell Medical College, White Plains, NY, (2)Psychiatry, Weill Cornell Medical College, White Plain, NY, (3)University of California Los Angeles, Los Angeles, CA, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: Parents' sentence diversity (operationalized as unique combinations of subjects and verbs) serves as a lexical model, promoting grammatical development in children (Hadley & Walsh, 2014). Parent-implemented intervention increases sentence diversity in typically developing toddlers, and more diverse lexical noun phrase subjects in parents significantly predict children's increased sentence diversity (Hadley et al., 2017). This relationship between parents' lexical flexibility and children's early grammatical growth is promising for children with ASD given that many early interventions are parent-mediated (Schreibman et al., 2015). However, it is unknown how parents' language input contributes to early grammar in children with ASD over the course of early intervention.

Objectives: We 1) measured changes in the sentence diversity in toddlers with ASD over the course of treatments; 2) examined the impact of caregivers' sentence diversity on children's language; and 3) identified the predictors of grammatical changes in parents and children.

Methods: Participants were drawn from 72 caregiver-child dyads with ASD who participated in early intervention programs. Preliminary data included 10-minute play sessions from 34 dyads (Time 1: M=30 months, SD=2.6; Time 2: M=36 months, SD=2.4). Sentence diversity was quantified with a number of unique subject-verb combinations for parents and children from the play sessions while adapting the existing coding scheme from Hadley et al. (2017). The Brief Observation of Social Communication Change (BOSCC; Grzadzinski et al., 2016) was used to assess children's social communication. Children were divided into two groups; those whose sentence diversity scores improved ("Improving" n=20) versus those whose were stable ("Stable" n=14) over time using the median score. Baseline cognitive and social communication skills of these two groups of children were compared using t-tests. Pearson's r correlations between parents' and children's sentence diversity change scores were examined.

Results: Preliminary analyses showed that sentence diversity in children increased significantly over the six months of treatment with a medium effect size (p<0.001, Cohen's d=.5). Parent sentence diversity improvement was marginally significant (p=0.055, d=.3). Parent and child sentence diversity scores were significantly correlated both at Time 1 (r=.5, p<.05) and Time 2 (r=.6, p<.001). Improvements in child sentence diversity from Time 1 to Time 2 were correlated with higher levels of parent sentence diversity at Time 2 (r=.4, p<.05). The Improving group had a higher baseline non-verbal IQ (Stable: M=73, SD=23.2; Improving: M=93, SD=11.5; p<0.01) and less social communication deficits (BOSCC Social Communication; Stable: M=27, SD=7.3; Improving: M=19, SD=5.5; p<0.001). Parents with higher education levels made more significant improvements in their sentence diversity (p<0.05).

Conclusions: Improvements in sentence diversity were examined in both children with ASD and their parents over the course of early interventions. Results also highlight the reciprocal interaction between increased parent sentence diversity and more advanced grammatical skills in toddlers with ASD. Higher cognitive skills and less social impairments may facilitate early grammatical growth in these children. Parental education level may also moderate changes in their lexical flexibility. The final analyses will employ generalized linear mixed models with a larger sample from an on-going study.

2:54 **187.004** Measuring Child Social Communication across Contexts: Similarities and Differences across Play and Snack Routines.

K. M. Frost[1], *G. N. Koehn*[2], *K. M. Russell*[2] *and B. R. Ingersoll*[1], *(1)Psychology, Michigan State University, East Lansing, MI, (2)Michigan State University, East Lansing, MI*

Background:

Measurement of treatment response is essential for understanding the efficacy of early interventions for autism spectrum disorder (ASD). Development of measures that capture meaningful outcomes across contexts while maintaining strong psychometric properties has been identified as a priority in the field (Lord et al., 2005; McConachie et al., 2015; Schreibman et al., 2015). The Brief Observation of Social Communication Change (BOSCC; Grzadzinski et al., 2016) is an observational rating scheme of brief play interactions, which was developed to capture short-term change in child social communication skills.

Objectives:

The goal of this study was to adapt the BOSCC to a new context, a snack routine, and evaluate the psychometric properties and validity of the BOSCC in both play and snack routines.

Methods:

Participants were 50 children (mean=46 months old) and their caregivers who participated in two research studies evaluating the efficacy of a low-dose parent-mediated intervention delivered via telehealth. Caregiver-child interactions of a play routine and a snack routine were filmed in family homes at three time-points (pre- and post-intervention, and a 3-month follow-up). A research-version of the BOSCC (BOSCC-Play) was used to rate play videos, and adaptations were made for application to snack videos (BOSCC-Snack). We evaluated the internal consistency and inter-rater reliability of both BOSCC-Play and BOSCC-Snack. In addition, the relationship between BOSCC-Play and BOSCC-Snack was evaluated concurrently and over time. Last, correlation and hierarchical regression were used to understand how BOSCC-Play and BOSCC-Snack predicted other measures of child skills.

Results:

Results show that the psychometric properties of the BOSCC when rated on snack routines remain strong, particularly for the social communication domain (Cronbach's alpha=0.87; ICC=0.93). The BOSCC Total Score was sensitive to change in both play routines and snack routines, although the trajectories were somewhat different across three time-points (see figure). However, the utility of the BOSCC for measuring restricted and repetitive behaviors (RRBs) is less clear. In addition to positive skew in RRB items, there were differences across the play and snack contexts (see table), and inter-rater reliability was lower, although still acceptable (ICC=0.70). Nonetheless, differences in RRBs across play and snack lend support for the claim that measurement across contexts is essential.

Conclusions:

Application of the BOSCC to two or more contexts may allow for more accurate estimation of intervention response and evaluation of the generalization of child gains in social communication. In addition, it may also provide a method for researchers to evaluate the effect of context on child social communication skills. Future research should attempt to evaluate the effect of parent behavior on BOSCC rating, as child social communication is likely to vary with differences in parent interaction style.

Oral Session - 11A
Epidemiology/Population Studies
188 - Epidemiology
1:30 PM - 2:25 PM - Room: 517B

1:30 **188.001** Preconception Health and Pregnancy Rates of Autistic Women in Ontario

Y. Lunsky[1], *H. K. Brown*[2], *L. A. Tarasoff*[3], *S. Chen*[4] *and A. Tint*[5], *(1)Azrieli Centre for Adult Neurodevelopmental Disabilities, Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Interdisciplinary Centre for Health & Society, University of Toronto, Scarborough, ON, Canada, (4)ICES, Toronto, ON, Canada, (5)CAMH, Toronto, ON, Canada*

Background: There is a growing recognition that preconception health, the health of all individuals of reproductive age, impacts reproductive and perinatal outcomes. However, very little is known about the preconception health of autistic women. Similarly, there is an absence of population level data on pregnancies in autistic women, although it is now widely recognized that pregnancies occur and that health supports could be strengthened. The current interest in the health of autistic women should extend to their preconception and reproductive health, so that health care providers can better attend to their unique needs, and support conception and healthy pregnancies for women who wish to become mothers.

Objectives: Our objectives were to first describe the preconception health characteristics of a population-based cohort of autistic women relative to women in the general population and to report on their pregnancy rates.

Methods: We conducted a population-based, cross-sectional study using Ontario health administrative data (2015-2016). We identified 15-44-year-old women with autism (n= 5,426) and women without any developmental, physical, or sensory disabilities (n=2,303,066). Preconception health variables were social (poverty), health (chronic disease, teratogenic medication use, mental illness, history of assault), and health care factors (continuity of care). We described these characteristics using frequencies and percentages and compared autistic women to those without disabilities using standardized differences, wherein differences >0.10 were considered to be clinically meaningful. We also describe the rates of live births, induced abortions and pregnancy losses in both groups.

Results: Compared to women without disabilities, autistic women were equally likely to live in poverty. They were more likely to have asthma and an unstable chronic medical condition although other medical conditions were not more common. They were more likely to have a psychotic mental illness, a mood/anxiety disorder, a substance use disorder, self-harm, or other mental illness and to have experienced assault. They were also more likely to be receiving teratogenic medications (1/3 of autistic women). However, they were more likely to routinely access the same primary care provider, indicating high continuity of care. Pregnancy rates were lower for autistic women than other women with an overall prevalence rate for autistic women of 16.4 per 1000 autistic women compared to 54.0 per 1000 women with no disabilities.

Conclusions: Research on factors contributing to poor preconception health among autistic women is needed, particularly with regard to their mental health, as are tailored interventions to improve preconception health for those women who wish to conceive. It will be important to explore whether lower pregnancy rates are consistent with the reduced desire of this group to become pregnant, or if there are other health or social contributors.

1:42 **188.002** A Nation-Wide Prevalence Study of Very Young Children with ASD in Bangladesh

S. Akhter[1] *and J. Shefa*[2], *(1)Institute for paediatric Neurodisorder and Autism IPNA, Dhaka, Bangladesh, (2)Bangabandhu Sheikh Mujib Medical University, Institute of Paediatric Neurodisorder and Autism (IPNA), Dhaka, Bangladesh*

Background:

The Bangladesh ASD Survey in Young Children 2017 was funded by the IPNA, a project under the Ministry of Health and Family Welfare of the Government of the People's Republic of Bangladesh. The survey was designed to assess the prevalence of this condition in young children from 16 to 30 months of age.

Objectives:

The main objective of this survey was to determine the prevalence of autistic spectrum disorder (ASD) on young children in Bangladesh. Another objectives of the survey were to detect the prevalence at urban-rural distribution in Bangladesh.

Methods:

A sample size estimate of 38,250 young children. Survey was done in 85 Primary Sampling Units/Enumeration Areas (PSU/EAs) – each PSU containing about 100 households – distributed among each of 30 randomly selected districts across eight divisions of the country. Rural and urban areas were selected proportionately.

Preparatory activities including training of survey personnel (Health Assistants, Heath Inspectors and Medical Officers) took place between January and April 2017 and actual data collection was in two phases – the first in May and June and the second in October and November 2017.

In the first step of the survey, Interviewers collected information as well as carried out household level screening of ASD among survey children using 'Red Flag'. Second step screening of ASD was done among all children referred as positive following Red Flag by trained Medical Officers using M-CHAT at Upazila Health Complex or Sadar (district) Hospitals. At the third and final stage, Expert Teams from Dhaka HQ (Paediatric Neurologists, Clinical and Educational Psychologists) diagnosed ASD with DSM-5 among all children referred after 'Red Flag' at the respective Civil Surgeon offices of sample districts.

Field monitoring was done by spot checks by Quality Control Officers (MO), Master Trainers from IPNA, HQ coordinators and local health administrators such as UHFPOs.

Data from the field was manually edited and entered. Data capturing, editing, cleaning, identifying missing data, duplication detection, analysis and tabulation processes were carried out using CSPro 7.1 and SPSS 21. All results presented in this report are calculated from weighted data

Results:

The survey was undertaken in 37,982 households (71% rural, 29% urban) distributed across eight divisions and containing 38,440 children (52% boys, 48% girls) aged 16-30 months. The prevalence of DSM-5 positive ASD in16-30-month-old children was 17/10,000 young children (boys 24/10,000, girls 9.8/10,000) – in other words 1 in 589 young children (1 in 423boys; 1 in 1,026girls). Rural prevalence was 14/10,000 and urban 25/10,000.

Conclusions:

This was one of the largest surveys of ASD in young children undertaken anywhere in the world. There were many challenges in its implementation. Despite the overall low prevalence of autism, prevention programmes need to start right away because of the higher prevalence of ASD detected in high income families with higher education and Bangladesh's rapid economic development. Further studies need to elucidate the reasons for the higher prevalence in the upper socioeconomic class. Detection and early intervention programmes need to be planned carefully to target those more in need.

1:54 **188.003** The Sex Ratio in Autism Spectrum Disorder and Its Relationship with Risk Factors and Associated Features

M. Matheis[1] *and J. L. Matson*[2]*, (1)Louisiana State University, Baton Rouge, LA, (2)Department of Psychology, Louisiana State University, Baton Rouge, LA*

Background: The higher prevalence of autism spectrum disorder (ASD) among males compared to females is well documented but poorly understood. A better understanding of the ASD sex ratio may provide valuable insight into the underlying neurobiological and genetic mechanisms of the disorder. Factors such as cognitive functioning, diagnostic subtype, comorbid disorders, birth weight, and parental age at birth have been found to affect the sex ratio, suggesting that males and females with ASD may be differentially impacted by associated risk factors and underlying neurobiology.

Objectives: This study had three main aims: 1) estimate the ASD sex ratio among children enrolled in EarlySteps, Louisiana's statewide early intervention program; 2) examine changes in the ASD sex ratio across specific phenotypes, risk factors, and associated features; 3) examine whether males and females with ASD are differentially impacted by factors associated with increased risk for ASD.

Methods: Participants (*n*= 12,598) were children aged 17-37 months (*M* = 25.43, *SD)* enrolled in EarlySteps, the State of Louisiana's early intervention program. The Baby and Infant Screen for Children with aUtism Traits- Part 1 (BISCUIT- Part 1) and Battelle Developmental Inventory, Second Edition (BDI-2) were administered to parents/caregivers as part of the EarlySteps assessment protocol. Diagnostic classifications were made through review of EarlySteps assessment results using *DSM-5* criteria for ASD. Bivariate analyses were conducted to examine the male/female (M/F) ratio across factors (i.e., race/ethnicity, ASD symptom severity, developmental delay, cognitive delay, maternal age, paternal age, birth weight, premature birth, multiple births, multiplex families, global developmental delay, Down syndrome, seizure disorder, cerebral palsy) and to examine difference in the mean number of risk factors between males and females with ASD. Hierarchical logistical regression models were used to examine risk factors in relation to ASD classification outcomes, with interaction terms between risk factors and sex allowing for the analysis of differential risk between the sexes.

Results: The overall ASD M/F ratio was 3.15. Significant differences in the M/F ratio were found: between cases with (3.05) and without cognitive impairment (3.26); between cases with (1.97) and without (3.41) advanced maternal age; across birth weight categories (<1500 g: 1.90, 1500-2499 g: 2.05, ≥2500 g: 3.79); and between cases with (1.62) and without (3.28) seizure disorder. Females with ASD had a significantly higher mean of risk factors compared to their male counterparts. Advanced maternal age was found to significantly increase the risk of ASD for females but not males (*OR* = 1.628, 95% CI [1.034-2.564],*p* = .035).

Conclusions: The found ASD M/F ratio of 3.15 is lower than many previous estimates, but similar to other recent population-level studies. The differential impact of risk factors such as advanced maternal age may have important implications for understanding underlying genetic mechanisms. Further research is needed examining the relationship between specific risk factors for ASD and the ASD sex ratio.

2:06 **188.004** Effect Modification By Maternal Diabetes during Pregnancy on the Association between Regional Air Pollution Exposure and Autism Spectrum Disorder

H. Jo[1]*, S. P. Eckel*[1]*, J. C. Chen*[1]*, M. P. Martinez*[2]*, T. Chow*[2]*, F. Lurmann*[3]*, A. H. Xiang*[2] *and R. McConnell*[1]*, (1)University of Southern California, Los Angeles, CA, (2)Kaiser Permanente Southern California, Pasadena, CA, (3)Sonoma Technology, Inc., Petaluma, CA*

Background: Recent studies found that both maternal diabetes during pregnancy and early life exposure to air pollution increase the risk of autism spectrum disorder (ASD). Potential common biological mechanisms of air pollution and maternal immune activation-related pregnancy complications such as diabetes may interact, including inflammation and systemic oxidative stress, which could adversely affect neurodevelopment. However, no study has evaluated the joint effects of maternal diabetes and air pollution on ASD.

Objectives: We evaluated ASD risk associated with prenatal and first year of life exposures to regional air pollution by maternal diabetes during pregnancy.

Methods: This retrospective cohort study included 246,420 singleton children born in Kaiser Permanente Southern California (KPSC) hospitals between 1999 and 2009. Children were followed from birth until age five. Using the local regulatory air monitoring data with inverse distance-weighted monthly averages interpolated to each geocoded residential birth address, we estimated the exposures to ambient ozone and other regional air pollutants, including particulate matter less than 2.5 μm in aerodynamic diameter ($PM_{2.5}$), PM less than 10 μm (PM_{10}), and nitrogen dioxide (NO_2) during each trimester and first year of life. Exposure-associated increases in the relative risks of ASD were estimated by hazard ratios (HRs) using Cox regression models to adjust for birth year, KPSC medical center service areas, and relevant maternal medical, pregnancy, sociodemographic, and child characteristics. Interactions of estimated exposures and a 4-level categorical variable for maternal diabetes (none, gestational diabetes mellitus (GDM) diagnosed <24 weeks' gestation, GDM diagnosed ≥24 weeks' gestation, and pre-existing type-2 diabetes) were tested. For each observed exposure window with statistically significant global interaction, HRs associated with the index pollutant exposure were estimated separately for each subcohort defined by the category of maternal diabetes during pregnancy.

Results: There were 2471 children diagnosed with ASD. Statistically significant interactions between maternal diabetes and ozone exposure during the first trimester (p=0.047) and first year of life (p=0.007) were observed. Risk of ASD was associated with ozone levels among mothers with GDM <24 weeks' gestation with adjusted HRs per 15.7 ppb ozone 1.50 (95% CI, 1.08-2.09) during the first trimester and 2.01 (95% CI, 0.67-6.07) during the first year of life. No statistically significant associations of ASD with ozone were observed in offspring of pregnancies without diabetes, GDM diagnosed at ≥24 weeks' gestation, or pre-gestational diabetes. No statistically significant interactions of diabetes were observed with $PM_{2.5}$, PM_{10}, and NO_2.

Conclusions: GDM diagnosed earlier in pregnancy may increase children's susceptibility to prenatal and early life ozone associated ASD risk.

189 - Developmental Trajectories
2:30 PM - 3:25 PM - Room: 517B

2:30 **189.001** Developmental Trajectories of Repetitive Behaviors in Preschoolers with and without Autism

J. Wolff[1], *A. F. Dimian*[1], *B. Pennington*[2], *K. Botteron*[3], *S. R. Dager*[4], *J. T. Elison*[1], *A. Estes*[4], *H. C. Hazlett*[5], *R. T. Schultz*[6], *L. Zwaigenbaum*[7], *J. Piven*[8] *and .. The IBIS Network*[5], *(1)University of Minnesota, Minneapolis, MN, (2)University of Minnesota Twin Cities, Minneapolis, MN, (3)Washington University School of Medicine, St. Louis, MO, (4)University of Washington, Seattle, WA, (5)University of North Carolina, Chapel Hill, NC, (6)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (7)University of Alberta, Edmonton, AB, Canada, (8)*Co-Senior Authors, IBIS Network, University of North Carolina, Chapel Hill, NC*

Background: There is evidence that restricted and repetitive behaviors (RRBs) are an early-emerging feature of autism spectrum disorder (ASD). We previously reported that RRBs were elevated in high-risk toddlers later diagnosed with ASD over the 12 to 24 month age interval (Wolff et al. 2014). In the present study, we provide a follow-up of our original study sample at preschool age by examining trajectories of repetitive behavior from 12 to 36 months age in a large sample of prospectively ascertained children at low and high familial risk for ASD.
Objectives: 1) Characterize trajectories of repetitive behavior from ages 12 to 36-48 months in infant siblings at high familial risk for ASD and a low-risk control sample; and 2) examine repetitive behavior trajectories in relation to key cognitive and behavioral outcomes.

Methods: Prospective, longitudinal parent-report repetitive behavior data (RBS-R; Repetitive Behavior Scale - Revised) were collected for 202 toddlers at high-risk for ASD and 53 low-risk controls (LR-Neg) at 12, 24, and 36 months of age. Fifty-two high-risk toddlers were classified with ASD at age 36 months based on clinical best estimate (HR-ASD). Longitudinal profiles of RRB across 5 subtypes were compared using generalized estimating equations. Relations of RRB to key cognitive and behavioral variables (i.e. IQ, adaptive behavior, and ASD symptom severity) were examined using nonparametric correlations.

Results: Longitudinal profiles for children with ASD differed significantly between groups on RBS-R composite and all subtype measures of repetitive behavior, $p \leq .001$. The HR-ASD group showed significantly higher rates of repetitive behavior across all RRB subtypes at the 12 month time point, with trajectories significantly diverging thereafter. Groups markedly differed across RRB subtypes by preschool age, with ritualistic and sameness behaviors showing the most dramatic change over time. Trajectories for high-risk children without ASD (HR-Neg) were intermediate to low-risk and ASD positive counterparts. Intercept, but not slope, of composite RBS-R scores were significantly associated with social skills ($F = 28.1$, $p < .001$) and communication scores ($F = 17.3$, $p < .001$) at age 36-48 months. Consistent with findings from age 24 months, RRBs were not associated with motor ability ($F = 3.6$, $p = .06$) or overall IQ ($F = 3.8$, $p = .051$).

Conclusions: These results build upon previous findings by demonstrating that subtypes of RRB develop in dynamic fashion over early childhood. For those diagnosed with ASD at age 36 months, RRBs were elevated at age 12 months, with developmental trajectories diverging sharply from non-ASD groups thereafter. These results further suggest that higher rates of RRB reported in preschoolers with ASD may be preceded by subtle but steady changes in behavior from later infancy and early toddlerhood.

2:42 **189.002** Developmental Trajectories of Social Vocal Behavior As Biomarkers for Autism During the First 24 Months of Life: Risk Status Vs. Diagnosis

M. Kumareswaran[1], *J. Bailey*[2], *S. Ghai*[1] *and G. Ramsay*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (2)University of Miami, Miami, FL*

Background: Although autism is difficult to diagnose reliably before two years of age, prodromal symptoms may emerge over time during the first twelve months of life. Due to natural variability in developmental timescales, cross-sectional measures of behavior usually fail to capture significant differences over this period. Current research suggests that early biomarkers of risk may be found instead by examining longitudinal trajectories of individual development. Experimental research has shown the importance of contingent interaction between infant and caregiver in scaffolding vocal development, which suggests that developmental profiles of early vocal behavior and vocal interaction may be candidate biomarkers for autism. In previous investigations, we found evidence for a developmental cascade in vocal development discriminating high-risk

and low-risk siblings, beginning at 12 months, with deficits in vocal contingency that lead to later deficits in adult and infant volubility, all of which were predictive of speech and language outcome at 24 months. In this follow-up study, we re-analyzed the developmental profiles of the same children according to diagnostic outcome at 24 and 36 months, to determine whether deficits in social vocal engagement appear earlier in infants who later receive a diagnosis, and whether high-risk siblings who do not go on to receive a diagnosis exhibit patterns that more closely resemble autism or typical development.

Objectives: The goal of this study is to determine the relationship between developmental profiles of social vocal engagement from birth to two years of age, risk status and diagnosis, to test whether early vocal development is a categorical indicator of outcome.

Methods: As part of an NIH Autism Center of Excellence, we tracked vocal development among 37 high-risk infant siblings with a family history of ASD and 35 low-risk controls. Each child wore a recording device (LENA) for one day every month from 0-24 months to provide audio recordings of their vocal behavior and natural language environment. Utilizing automatic speech recognition technology developed by our laboratory, we identified the number of vocalizations per hour for infant and caregiver, and calculated the rate of contingent interactions based on timing statistics. Using Functional Data Analysis, we determined developmental trajectories for each child and mean developmental trajectories by group, based on risk status and diagnostic outcome: 10 children were diagnosed with ASD, 27 were DD/BAP, and 35 were typically developing.

Results: The developmental cascade linking early declines in vocal interaction to later declines in adult volubility and subsequent declines in infant volubility is exaggerated in infants diagnosed with ASD. Differences that only became apparent at 12 months between high-risk and low-risk infants are present between infants with ASD and typically developing peers within the first year of life. Developmentally delayed or BAP infants resemble typically developing infants at birth, but transition towards developmental trajectories resembling infants with ASD by the second year of life.

Conclusions: Developmental trajectories of social vocal engagement over the first two years of life differentially predict diagnostic outcome at two years of age in children with ASD and developmentally delayed and typically developing controls.

2:54 **189.003** Change in Core Symptoms from Ages 2 to 19 and Relative Stability from Ages 19 to 25 on the Adapted-ADOS, a New Instrument to Assess Minimally Verbal Adults

V. Bal[1] *and C. Lord*[2]*, (1)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (2)University of California Los Angeles, Los Angeles, CA*

Background: Parent-reported ASD symptoms show different patterns of change across childhood and adolescence, depending on the individual's age, language or IQ (e.g., Bal et al., 2018, McGovern & Sigman, 2005). Change in symptoms across childhood and adolescence has implications for diagnosis of ASD in adults. Additionally, identification of symptoms that remain stable across development may lead to a better understanding of mechanisms underlying observable impairments. To date, studies examining symptom trajectories are largely based on parent-report instruments or limited to comparisons of symptoms from direct observation measures, such as the ADOS-2, across childhood (e.g., Gotham et al., 2012). Longitudinal comparisons of symptoms captured on the ADOS-2 are hindered by a lack of appropriate instruments to assess older minimally verbal (MV) individuals. While there are different modules for verbally fluent children and adults (Modules 3 & 4), adaptations to the Modules 1 and 2, designed for use with children with less language, are needed to improve their utility with MV adults.

Objectives: To describe the Adapted-ADOS, a new tool designed for use with MV adolescents and adults and use A-ADOS scores to explore changes in the manifestation of ASD in young adulthood.

Methods: Diagnostic algorithms were derived from 160 adolescent and adult assessments [124 ASD, 36 Non-ASD, Mean age=19.18 (3.06) years]. McNemar's test assessed change in the presence or absence of impairment of symptoms at ages 2 and 19 for 60 participants with ASD. Paired-samples T-tests compared A-ADOS totals in 35 participants seen at ages 19 and 26.

Results: Sensitivity was above .8 for all algorithms; specificity ranged from .56 (M1-No Words) to .88 (M1-Some Words). In the longitudinal sample, many adults demonstrated improvements in the areas of response to joint attention (X^2=28.27, p<.001) and gestures (X^2=13.89, p<.001), with significantly fewer participants exhibiting impairments on these items at age 19 compared to age 2 (RJA: 20% vs. 98%; gestures: 60% vs. 93%, respectively). In contrast, impairments in spontaneous initiation of joint attention and facial expressions appeared to persist into adulthood (Table 1). From ages 19 to 26, A-ADOS totals were relatively stable [t(34)=.90, p=.38, Figure 1]. Total scores remained stable or improved for 21 participants (Mdiff=3.10), but worsened for 14 adults (Mdiff=-3.4). The worsening group showed decreased engagement from 19 to 26, both with the examiner [t(13)=-2.69, p<.05] and the A-ADOS activities [t(13)=-2.48, p<.05].

Conclusions: The A-ADOS expands the repertoire of instruments to assess MV adolescents and adults and provides an alternative to the ADOS-2 modules 1 and 2 for assessment of older individuals. Consistent with parent report, adults exhibit both improvements (e.g., response to joint attention, gestures) and persistent impairments (e.g., facial expressions) in directly-observed symptoms considered to be core features of ASD in childhood. Preliminary analyses of a small sample suggest that symptoms appear relatively stable across young adulthood; however, a subset of MV adults may be at risk for decreased engagement during the transition years. Further analyses will explore factors that may explain the observed behavioral change (e.g., onset of depression; loss supports [see Taylor & Seltzer, 2010]).

3:06 **189.004** Trajectories of Autism Severity in Children from Toddlerhood to Childhood in Taiwan: The Roles of Maternal Education Level and Residence Area

C. H. Chiang[1]*, K. C. Lin*[2]*, C. C. Wu*[3]*, T. L. Lin*[2] *and C. L. Chu*[4]*, (1)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (2)Department of Psychology, Taipei, Taiwan, (3)Department of Psychology, Kaohsiung Medical University , Kaohsiung, Taiwan (Province of China), (4)Department of Educational Psychology & Counseling, National Pingtung University, Pingtung, Taiwan*

Background: Literature had shown that autism spectrum disorder (ASD) is characterized by heterogeneous severity. However, most of recent studies were done in the West, seldom in the East. As the authors know, this is the first longitudinal study for 6 years from toddlerhood to childhood in Taiwan, to explore the developmental trajectories of autism symptom severity and its early predictors.

Objectives: Two study purposes: (1) to plot longitudinal trajectories of ASD severity from early childhood to elementary school period; (2) to find the early indicator to explain the different trajectory classes in the children with ASD.

Methods: Seventy children with ASD participated at time 1 (mean chronological age was 2.5 years old), and then followed at time 2 (mean

chronological age was 4 years old) and time 3 (mean chronological age was 8.5 years old). Participants recruited from two local areas in Taiwan, 33 of them were from Taipei city, the capital area in Taiwan, and 37 of them were from Chia-Yi city and county, the rural area in Taiwan. The study assessed the autism symptom severity by ADOS and cognitive function by MSEL WPPSI-IV, or WISC-IV at three time points. Additionally, early indicators including maternal education level, child's FSIQ, VIQ, NVIQ at Time 1, and age of first autism sign in ADI-R. Due to different modules were used in ADOS across three time points, ADOS total CSS (calibrated severity score) was used for analysis.

Results: In hierarchical cluster analysis, three classes model was found to represent the observed data. We found that 27% (n = 18) of participants were assigned to persistent high severe class, 61% (n = 43) of participants were assigned to worsening class and 13% (n = 9) of participants were classified as improving class. The proportions of the three classes among two areas revealed that the children living in Chia-Yi were more likely to be classified as worsening group (n = 30, 81%) and no one be classified as improving group. Using multinomial logistic regression analysis, we found only two variables, i.e., maternal education level ($p < .01$) and area ($p < .000$) can explain the subgrouping independently. However, when the former two variables were put into the multinomial logistic regression model simultaneously; the effect of maternal education level was disappeared and the area variable ($p < .000$) was the only significant indicator to explain the subgrouping.

Conclusions: In summary, this study showed that all of the participants with ASD were classified as persistent high, worsening and improving groups with three time points from toddlerhood to elementary school ages. However, the children with ASD living in the rural area such as Chia-Yi were more likely to be classified as worsening group. Additionally, only the residence area could explain the ASD subgrouping. The accessibility and quality of service system of early intervention in two areas are discussed.

Oral Session - 12A
Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational
190 - Adult Outcomes
1:30 PM - 2:25 PM - Room: 518

1:30 **190.001** Can Executive Functions Predict Study Progress Among College Students with Autism?

*R. Dijkhuis[1], L. M. de Sonneville[2], **T. Ziermans**[3], W. G. Staal[4] and H. Swaab[2], (1)University of Leiden, Leiden, Netherlands, (2)Leiden University, Leiden, Netherlands, (3)University of Amsterdam, Amsterdam, Netherlands, (4)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands*

Background: Many students with Autism Spectrum Disorder (ASD) that enter higher education drop out prematurely. Although studies have shown that executive functioning (EF) skills can predict study success in neurotypical individuals, it is unknown whether this is also true for young adult individuals with ASD.

Objectives: To determine whether daily EF and performance-based EF can predict study progress in college students with ASD.

Methods: Fifty-four young adults college students with ASD (M_{age} = 22.48, SD = 2.43, 72% male) were recruited and followed-up for 6 months to determine their study progress. At baseline the adult self-report version of the Behavior Rating Inventory of Executive Functioning (BRIEF-A) and computerized subtasks of the Amsterdam Neuropsychological Tasks (ANT) were assessed to measure daily EF and performance-based EF, respectively. The Social Responsiveness Scale for Adults (SRS-A) was included to assess autism symptom severity. After six months the total proportion of collected study credits was calculated. Correlational analyses and regression models were conducted to determine the best predictors of study progress.

Results: The initial results showed that cognitive flexibility, working memory (both ANT), and planning/organizing skills (BRIEF) were significantly correlated with study progress. Subsequent regression analyses indicated that although these EF skills were able to explain a significant amount of variance in study progress, only planning/organizing skills was a significant predictor above and beyond autism symptom severity.

Conclusions: These preliminary findings suggest that mapping daily EF in young adults with ASD in higher education can potentially aid in increasing their odds of a successful academic outcome.

1:42 **190.002** The ASD Mentoring Program at York University, Canada: Identifying Mental Health Needs and the Benefits of Social Support

***J. M. Bebko**[1], C. A. McMorris[2], M. Ames[3], B. L. Ncube[4] and K. T. Shaikh[1], (1)York University, Toronto, ON, Canada, (2)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (3)University of Victoria, Victoria, BC, Canada, (4)Psychology, York University, Toronto, ON, Canada*

Background:

Young adults with ASD are at risk for academic and personal failure throughout their post-secondary education, due to co-occurring mental health issues, along with the difficulties in social relationships and communication characteristic of ASD (Pinder-Amaker 2014). We summarize two projects: one investigating these mental health issues and barriers for service, and one reporting on the social support experiences of students who participated in the first decade of the York University (Ontario, Canada) ASD Mentoring Program (AMP). The AMP is a peer mentorship program providing individual and group activities to help achieve individualized goals.

Study1:

Objectives: Identify the frequency of mental health issues in AMP participants, their service utilization patterns, and barriers to accessing needed services.

Methods: Participants: 45 students enrolled in the AMP between 2013-2017. 82% were male, average age at program entry was 21 years (SD= 2.38)

Procedure:Students completed an initial interview with their mentor, querying self-disclosed ASD and secondary mental health diagnoses, service utilization, and barriers in accessing services.

Results: The majority of participants (56%) reported at least one additional mental health diagnosis, with half of these (52%) indicating two or more. Most common were anxiety disorders (31%) and mood disorders (24%). Over half of students utilized one or more services in addition to AMP (range = 1–7). 40% of students indicated there were supports they would like to receive but were not currently accessing. The most commonly

reported barrier was self-imposed: a desire to handle problems on their own. Other common barriers included wait time and the steps to accessing services being overwhelming.

Conclusions:

Transitioning to post-secondary institutions can exacerbate risk of mental health issues in individuals with ASD. Participants indicated multiple barriers to access mental health services. We identify strategies to support students to increase probability of successful post-secondary experience.

Study2.

Objectives: We evaluated which aspects of social support were most used and valued by a subset of students enrolled in the York University AMP.

Methods: Participants: 25 students, males=78%, mean age=21.43 years (SD=3.76) in their first year in AMP.

Procedure: Participants completed questionnaires at the beginning and end of the academic year. Goals for participation were collected at the beginning of the year; additional measures at the beginning and end of the year included social support and friendship questionnaires, as well as ratings of how well they had achieved their goals and satisfaction.

Results: Topics addressed in individual meetings included social skills and coursework (87% of participants), followed by dating/romantic relationships (43%). 77% indicated they had achieved their goals (most common: develop/improve social skills and friendships), and 77% indicated the program had been helpful in goal achievement. Satisfaction with AMP was high (M=4.22/5, SD=0.60) and with individual meetings (M=4.52/5, SD=0.59).

Conclusions: Social support is a major barrier for educational attainment for students with ASD (Cai and Richdale, 2016). Our findings reinforce the benefit of providing a targeted mentoring program focusing largely on social skills, even after only one year in the program. The AMP model has been successfully adapted by other institutions.

1:54 **190.003** Examining the Efficacy of a Community College Program Supporting Transition to Adulthood for Individuals with ASD

L. G. Klinger[1], *K. M. Dudley*[2], *R. K. Sandercock*[3], *G. Osborne*[4], *T. Dawkins*[5] *and M. R. Klinger*[6], *(1)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (2)Department of Psychology & Neuroscience, UNC Chapel Hill; TEACCH Autism Program, Carrboro, NC, (3)Department of Psychology & Neuroscience, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)UNC TEACCH Autism Program, Greensboro, NC, (5)The University of North Carolina - Chapel Hill, Carrboro, NC, (6)UNC TEACCH Autism Program, Chapel Hill, NC*

Background: The dramatic increase in the rate of individuals with ASD graduating high school with a general education diploma has created challenges for higher education professionals and employers who are seeking evidence-based supports. Few interventions exist that target the employment readiness "soft skills" that are often associated with poor outcomes (e.g., executive function, social competence, emotion regulation). The TEACCH School Transition to Employment and Post-secondary Education (T-STEP) program was designed to target these skills. Community colleges represent an ideal location to provide transition interventions as many adolescents with ASD continue their education in community colleges. The T-STEP was offered in community colleges through a statewide Vocational Rehabilitation Pre-Employment Transition Services program.

Objectives: We implemented an open trial, community college version of the T-STEP across 3 community college campuses. The objectives of this open trial were to (1) provide initial efficacy data for this community-college intervention; and (2) create a behavioral observation measure (the Job Skills Assessment Profile) to assess meaningful outcomes associated with successful transition to adulthood.

Methods: Across three community colleges (7-12 students per semester), 31 adolescents and young adults (16-21-years old) with ASD completed a 24 session (90 minutes each) T-STEP course at their local community college. Students had completed or were completing a general education high school diploma. In addition to the T-STEP class, students received academic and career counseling services. Two measures of employment readiness were evaluated at pre- and post-assessments. The JSAP consists of two simulated work experiences (each 20 minutes) with a series of presses that prompt for organization skills, social skills, and emotion regulation skills. A total score is computed along with subdomain scores for each area. Two versions of the JSAP were created to avoid practice effects; versions were counterbalanced across time; videos were coded by blind raters. Caregivers completed an employment readiness measure, the Becker Work Adjustment Profile (BWAP) measuring 4 domains, Work Performance, Interpersonal Relations, Work Habits, and Cognitive Skills. Finally, during one semester (N = 18) self-report measures of self-advocacy (AIR Self Determination Scale) and symptoms of depression (Center-for Epidemiological Studies – Depression) were evaluated.

Results: Employment readiness skills improved on both measures (see Table 1). On the JSAP, participants showed a significant decrease in total workplace behavioral difficulties, improving from a score of 13.00 at baseline to 7.03 post-intervention [$t(28) = 4.80$, $p < .001$], with significant improvements across all domains (Organization, Social Skills, and Emotion Regulation). On the BWAP, a significant 17.3 point increase in scores from baseline to post-intervention was seen [$t(30) = 5.52$, $p < .001$] with significant improvements across all domains. Significant reductions in depression symptoms and increases in self-determination were also reported.

Conclusions: Results provide promising efficacy evidence for the T-STEP in a community-college environment targeting meaningful outcomes of employment readiness, self-determination, and symptoms of depression. The JSAP also appears sensitive to the employment readiness skills taught during the T-STEP and is a promising measure for other transition intervention studies. Next steps include an RCT and long-term measures of postsecondary and employment outcomes.

2:06 **190.004** Mock Juror Perceptions of Credibility and Culpability in an Autistic Defendant

K. Maras[1], *I. Marshall*[2] *and C. Sands*[2], *(1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom*

Background:

For a small minority of autistic individuals, characteristics linked to clinical features of autism are associated with engagement with the police and criminal justice system as an offender. However, little is known about whether legal professionals and jurors take autism-related factors into account when making judgements about their offending behaviours. Furthermore, an autistic person may be viewed as strange or awkward in court. This is potentially critical because observers often base their judgments of an individual's credibility on verbal and non-verbal cues such as

eye-contact, body movements, fidgeting, surface features of speech, and displays of emotion (DePaulo et al., 2003). However, several studies have recently reported that informing observers of an individual's autism diagnosis results in significantly more favourable judgements about them in everyday contexts (e.g., Sasson & Morrison, 2017).

Objectives:

The aim of the present study was to examine mock juror perceptions of credibility and culpability of a defendant who is described as displaying autistic-like characteristics and behaviours, and whether the provision of information about the defendant's autism diagnosis alters these perceptions.

Methods:

160 jury-eligible participants read a vignette describing a 27-year-old male who was brought to the attention of police for suspicious and aggressive behaviours and displayed unusual behaviours once in court. Half of participants were informed that he had a diagnosis of autism and read a report from a forensic psychiatrist about what autism is and how the defendant was affected by it ('*Label+info'*); the other half received no diagnosis label or further information ('*No info'*). Participants then rated the defendant's credibility, in terms of likability, cognitive functioning, and honesty, as well as perceived blameworthiness, guilty verdict and sentencing leniency. Participants' responses to follow-up open ended questions formed the basis of a qualitative analysis of the reasons for their ratings and judgements

Results:

Participants in the *Label+info* rated the defendant as significantly more honest, $F(1,158)=14.96$, $p<.001$, $\eta p^2=.09$, and likable, $F(1,158)=7.47$, $p=.007$, $\eta p^2=.05$, and less blameworthy, $t(158)=4.89$, $p<.001$, $d=0.78$, than those in the *No label* condition. There was no significant effect of information condition on ratings of cognitive functioning, $F(1,158) =0.90$, $p =.411$, $\eta p^2 =.004$. There was a significant association between the information that mock jurors received about the defendant's diagnosis and their beliefs regarding whether he should receive a guilty or not guilty judgement, $\chi 2(1, N =159) =8.13$, $p =.004$ (Figure 1). *Label+info* participants also reported more lenient sentencing attitudes towards the defendant, $t(98)=2.20$, $p=.030$, $d=0.45$.

Thematic analysis revealed that participants in the *Label+info* condition were more empathetic and attributed the defendant's behaviours to his autism and mitigating factors, while participants in the *No label* condition perceived the defendant as deceitful, unremorseful, rude and aggressive.

Conclusions:

The information provided to jurors about an autistic defendant can have a profound effect on their judgements of his likeability, honesty, blameworthiness, guilt and sentencing. This has important implications not only for the courts, but also for other areas such as employment and social situations where the disclosure of an individual's autism diagnosis may impact others' perceptions of them.

Oral Session - 12B
Family Issues and Stakeholder Experiences
191 - Caregiver Experience/Participatory Research
2:30 PM - 3:25 PM - Room: 518

2:30 **191.001** Juggling Multiple Roles: The Experience of Caregivers of Adults with ASD

N. Bagatell[1]*, E. M. Lamarche*[2] *and L. G. Klinger*[3]*, (1)University of North Carolina at Chapel H, Chapel Hill, NC, (2)Psychiatry, University of North Carolina at Chapel H, Chapel Hill, NC, (3)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Most adults with autism spectrum disorder (ASD) require support to live as independently as possible. This support often comes from unpaid caregivers, such as parents. While there is a robust literature regarding caregiving experiences of parents of children with ASD, relatively little research has focused on caregivers of adults. The scant literature has focused largely on coping and burden, with little attention to what caregivers actually do.

Objectives: The objective of this study was to explore caregiving for adults with ASD to inform service delivery and policy. The main research question this study addressed was: What roles do caregivers of adults with ASD enact to support their adult child? In essence, what does caregiving actually entail?

Methods: This descriptive qualitative study was part of the second phase of a larger study investigating outcomes of adults with ASD. The participants were individuals who identified as unpaid caregivers for 31 adults (ages 27-51) (see Table 1). Data were collected using a two-part interview comprised of the Vineland Adaptive Behavior Scales (2nd edition) Parent/Caregiver interview and a semi-structured interview. Interviews were recorded and transcribed. The semi-structured interviews, which lasted 30-60 minutes, focused on hopes and plans for the future and service utilization while the Vineland provided qualitative information about everyday life. Following each interview, reflexive memos were written; in this memoing process, the theme of caregiving emerged. The data analysis process, which involved multiple people, included reading transcripts, coding, grouping codes into categories, and recoding to confirm categories. Through ongoing discussions, themes were confirmed with members of the research team not involved in the coding process.

Results: Three main categories of caregiver roles, each with subthemes, were identified: 1) meeting and managing adult child's daily needs through planning social activities and assisting with basic self-care and instrumental activities of daily living; 2) obtaining services and supports by advocating and navigating systems; and 3) providing supports by being a culture broker, coach, and life line when the unexpected occurred. All caregivers carried out these roles to some degree regardless of the adult child's IQ, sex, and adaptive behavior skills. Caregivers whose adult children lived independently and those whose children lived in residential settings continued to carry out many roles. While caregivers did not convey a strong sense of burden, some expressed fatigue and concern regarding their own health status. Looming large for all caregivers was the question: "Who will do these things when I am no longer able?"

Conclusions: Caregivers of adults with autism across the spectrum enact many roles on a regular basis to promote the quality of life for their adult child. The findings have implications for service provision and policy. First, services should focus on increasing independence through daily living skills and self-advocacy interventions for individuals with ASD across the life span. Second, support should be provided to caregivers so

that they can engage in role release to enhance their quality of life as they age and to provide peace of mind regarding their adult child's future.

2:42 **191.002** Child Impact on the Family and Parent Social Support in Families of Children at Risk for Autism Spectrum Disorder

E. Hickey[1], *S. Broder-Fingert*[1,2], *J. L. Kuhn*[3], *J. Goupil*[1], *A. Chu*[4], *J. E. Rosenberg*[1], *M. Augustyn*[1,2] *and E. Feinberg*[2,4], *(1)Boston Medical Center, Boston, MA, (2)Boston University School of Medicine, Boston, MA, (3)Pediatrics, Boston Medical Center, Boston, MA, (4)Boston University School of Public Health, Boston, MA*

Background: Having a child with autism spectrum disorder (ASD) has been shown to impact parenting experiences (Estes et al., 2013), the family financial situation (Lavelle, 2014), the parent marriage or couple relationship (Hartley, DaWalt, & Schultz, 2017), siblings (Shivers, McGregor, & Hough, 2017), and parent social support (Lu et al., 2015); yet, little data has explored the specific impact of child functioning, or potential moderators of these relationships.

Objectives: The current study explored the impact of child functioning on the family, and assessed the role of parent social support in this relationship. Our research questions were: (1) Is child social functioning associated with child impact on positive feelings about parenting, negative feelings about parenting, parent social life, family finances, parent marriage/couple relationship, and/or siblings? (2) Does parent social support moderate the relation between child social functioning and child impact on feelings about parenting?

Methods: Data were collected from 320 parents/guardians of children, aged 15-34 months (*M* = 21.10, *SD* = 3.67), identified as "at-risk" on the Modified Checklist for Autism in Toddlers (M-CHAT; Robins, Fein, Barton, & Green, 2001) during routine screening for ASD across 14 urban pediatric clinics. This data was baseline data from participants enrolled in an NIMH funded randomized controlled trial of Family Navigation. Parents reported on the child's adaptive social behavior (ABAS-II; Rust & Wallace, 2004), their perceptions of the child's impact on the family, as measured by six subscales (positive feelings toward parenting, negative feelings toward parenting, impact on parent social life, financial impact, impact on marriage, and impact on siblings) of The Family Impact Questionnaire (FIQ; Donenberg & Baker, 1993), and parental social support, measured by the Medical Outcome Study Social Support Survey (MOS-SSS, Sherbourne & Stewart, 1991). Structural equation modeling within Analysis of Moment Structure (AMOS, version 21.0; Arbuckle, 2012) was used for analyses**.**

Results: Child social functioning significantly impacted both positive (β=.23, *SE*=.05, *p*<.001), and negative (β=-.12, *SE*=.05, *p*=.026) feelings about parenting, parent social life (β=-.19, *SE*=.06, *p*<.001), and siblings (β=-.15, *SE*=.07, *p*=.028). Parent social support did not moderate this relation, but there was an independent effect of social support on positive (β=.29, *SE*=.05, *p*<.001), and negative (β=-.27, *SE*=.05, *p*<.001) feelings about parenting, family finances (β=-.11, *SE*=.06, *p*=.047), and parent marriage/couple relationship (β=-.39, *SE*=.07, *p*<.001). Other variables, such as parent language (β=-.19, *SE*=.08, *p*<.001) and child age (β's=.12-.19., *SE*'s=.02-.02, *p*=.002-.045) were also independently related to the level of child impact on the family

Conclusions: Results highlight the importance of child social functioning and parent social support in understanding the impact a child at risk for ASD has on the family, but suggest that social support did not operate as a moderator. Other variables, such as language and child age, should be considered as potential moderators for future attempts to improve parental well-being of children at risk for ASD.

2:54 **191.003** Person-Oriented Ethics in Autism Research: Recommendations for Researchers Developed in Collaboration with Participants, Families, and Other Stakeholders

A. Cascio[1,2], *J. A. Weiss*[3] *and E. Racine*[1], *(1)Institut de recherches cliniques de Montréal, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada, (3)Psychology, York University, Toronto, ON, Canada*

Background:

Ethics is an important consideration in any research project, whether involving human subjects, biorepositories, big data, animal models, and so on. Research ethics is not limited to regulatory considerations, paperwork, and consent forms. It also addresses every day considerations such as respecting participants, considering broader social contexts, and attending to relationships between different people involved in conducting, participating in, and applying research.

Objectives:

The goal of this project is to collaborate with stakeholders to develop recommendations for research ethics regarding participants on the autism spectrum.

Methods:

A scoping literature review was conducted to develop the model of person-oriented research ethics. A systematic-interpretive literature review method was followed in order to identify research ethics issues in autism research. Task force deliberation was used to develop best practices in collaboration with autistic self-advocates, parents, professionals, researchers, and advocacy organization representatives. The work of the task force was advised by broader community engagement through a project website and ongoing conversation with community members.

Results:

The task force has produced a report containing suggestions according to the five guideposts of person-oriented research ethics: respect for holistic personhood, acknowledgment of lived world, individualization, focus on researcher-participant relationships, and empowerment in decision-making. Both conceptual and concrete recommendations are included. Conceptual recommendations include considering the difficulties participants and families may be facing in accessing care, being aware of autism and autistic communities and social groups who have a stake in research, and being mindful of stigma when writing up results. Concrete recommendations include, among others, strategies for creating more accessible documentation and practices such as using more visual communication strategies alongside text and verbal strategies; strategies for reducing anxiety by providing preparatory materials such as Social Stories or letting participants familiarize themselves with the experiment room in advance; and strategies for recognizing the contributions of autistic people as participants and otherwise, such as citing autistic authors.

Conclusions:

Research ethics is important to both researchers and participants as well as broader communities of scientists, families, and people on the spectrum who are all stakeholders in ethics issues. Ethics concerns are fruitfully addressed through engagement with stakeholders. This project has used the strength of this approach to develop best practices for researchers. Future research will implement and evaluate these suggestions

in the course of ongoing research projects.

3:06 **191.004** The Effects of Disclosing a Diagnosis of Autism on Social Perception and Behaviour in a Collaborative Game Task

B. Heasman[1] *and A. Gillespie*[2]*, (1)UCL Centre for Research in Autism and Education, London, United Kingdom, (2)Department of Psychological and Behavioural Science, London School of Economics and Political Science, London, United Kingdom*

Background: A constituent part of the social difficulties that autistic people experience is a lack of understanding about autism. This shapes the way non-autistic people perceive and extend social opportunities towards autistic people. Research on how autistic people are perceived by neurotypical people indicates that disclosing a diagnosis leads to a broadly positive discriminatory bias, but autistic testimonies indicate that diagnostic disclosure often results in negative discriminatory behaviour. This perception-behaviour gap is methodologically challenging to study because interactions are idiosyncratic and autism encompasses a broad range of behaviours. To address these challenges, the present study simulated interactions in an online game, where participants were led to believe they were collaborating with another human when in truth their partner was an intelligent virtual agent (hereafter, "Agent") that performed the same across all conditions.
Objectives: To determine the effect of diagnostic disclosure, on in-game behaviour and post-game self-report, in order to probe the perception-behaviour gap in diagnostic disclosure of autism.

Methods: We led participants (n = 256) to believe that they were interacting online with a real person, while playing Dyad3D, a maze navigation game where players must work together to open doors and complete the levels. The diagnostic status of the other player for participants was manipulated, with participants randomly assigned to one of three conditions: a no disclosure condition, without diagnostic information; a dyslexia disclosure condition; and an autism disclosure condition. However, in all conditions participants were actually playing with an Agent programmed to behave exactly the same way across all interactions. A post-game questionnaire recorded participants' self-reported perceptions of the interaction, including levels of coordination and helpfulness. Behavioural measures of participant activity in the game were also recorded, such as the mean distance from the Agent (coordination), and frequency of opening doors in the maze for the Agent (helpfulness).

Results: Our findings show that Dyad3D proved to be an efficient and viable method for creating a believable interaction (deception success rate >96%). Diagnostic disclosure of autism resulted in the Agent being perceived as more intelligent and useful, compared with either the no-diagnosis ($p < .001$) or dyslexia condition ($p = .028$). However, a comparison of self-reported helpfulness with in-game metrics showed no significant association between perception of helpfulness towards the Agent and actual helping behaviour towards the Agent ($p = .667$).

Conclusions: The findings suggest a "helping-bias", whereby individuals who receive knowledge of another person's diagnosis of autism over-estimate their own helpfulness towards the diagnosed individual. This finding highlights a risk that if autistic people claim they are not being helped adequately by non-autistic others, non-autistic others would not see such claims as having legitimacy.

Panel Session
Animal Models
192 - Innovative Outcome Measures Relevant to ASD in Preclinical Models
3:30 PM - 5:30 PM - Room: 517C

Panel Chair: Jill Silverman, *MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA*

Autism spectrum disorders include broad definitions of behavioral phenotypes and reflect the current consensus that the causes and clinical presentations of autism are highly heterogeneous. Although forging definitive links between genetic alterations and behavioral impairments is challenging, it is not insurmountable task. Translational endpoints, including behavioral outcomes, are essential for studying mechanisms of neurodevelopmental disorders and developing therapeutic treatment strategies. And while not all behaviors and phenotypes studied in the laboratory are robust, reliable, or clinically relevant, there are many that are prime and valuable for enabling translational experiments. Our proposed symposium will highlight four speakers whose research highlights robust and reliable behavioral and physiological outcome measures and innovative parameters that can be assessed in both humans and animals. Our speakers will discuss optimizing what behavioral data can tell us and what it cannot, and how to be cautious consumers of behavioral data. We will discuss how multiple domains of behavioral phenotypes and cross species studies could/should be embraced to improve translational efforts. We will also demonstrate how pairing behavior with a physiological marker can corroborate and expand translational research and how these innovative measures can facilitate studies and better predict clinical success for ASD and neurodevelopmental disorders.

3:30 **192.001** Improving Translation in Animal Models: The Science, Art, & Anecdotes

S. J. Rizzo, *Department of Neurobiology, Department of Medicine - Aging Institute, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Animal models are highly valuable tools for investigating the underlying pathophysiology, genetics, and neurocircuitry of neurodegenerative, neuropsychiatric, neurodevelopmental, and cognitive disorders. Translational endpoints, including behavioral outcomes, are essential for studying these CNS disorders and in particular for Autism Spectrum Disorders (ASD) where diagnostic criteria are largely based on behavioral criteria. Not all behaviors and phenotypes studied in animal models are robust, reliable, or optimal for enabling translational experiments leading to interpretable findings for clinical populations. Indeed, preclinical testing in animal models is critical for drug discovery, and while hundreds of interventions have demonstrated efficacy in animal models, successful translation to the clinic has been limited. Importantly, the preclinical studies that have enabled these clinical trials have largely used male subjects of a single inbred strain which is not analogous to the genetically diverse patient population; nor should it be expected that a single mutation on an inbred strain would recapitulate the diverse spectrum of behavioral phenotypes observed in such complex disorders as ASD. While historically preclinical screening of test compounds have employed behavioral endpoints in animal models as the primary screen owing to a falsely perceived ease of conducting these experiments; there have been compromises on the level of rigor, including blinding, randomization, inclusion of relevant controls, appropriate planned sample sizes, and *apriori* inclusion and exclusion criteria. Critically, an understanding of a test compound's pharmacokinetic (PK) and pharmacodynamics (PD) properties is necessary to aid in the selection of relevant and target specific dose ranges, route of administration, and

pretreatment regimen for testing, and these PK/PD modeling data are oftentimes not generated. Moreover, having knowledge of a test compound's therapeutic window, as defined by the dose range that produces the specific pharmacodynamic response relative to the dose range at which adverse or neurotoxic effects occur is crucial to appropriately interpreting the resulting data and its translational utility.
Conclusion: The outcome of implementing these considerations will be discussed in order to improve and enhance the utility of animal models for clinical translation.

Methods: N/A

Results: N/A

3:55 **192.002** Translation in Fast Forward: Cross Species Research on Deletions and Duplications of Chromosome 15q11.2-q13

***J. L. Silverman**, MIND Institute and Department of Psychiatry and Behavioral Sciences, University of California Davis School of Medicine, Sacramento, CA*

Background:
Mutations in chromosomal region 15q11.2-q13 result in at least three neurodevelopmental disorders including Angelman, Prader-Willi and Dup15q Syndromes, all associated with autism spectrum disorders (ASD). Angelman Syndrome (AS) is a rare neurodevelopmental disorder characterized by developmental delay, impaired receptive and expressive communication skills, ataxia, motor and balance deficits, poor attention, intellectual disabilities, microcephaly, and seizures. The genetic cause of AS is loss of expression of *UBE3A* (ubiquitin-protein ligase E6-AP) in the brain, typically due to a deletion of the maternal 15q11-q13 region. Duplications or triplications of chromosome 15q11.2-q13 (Dup15q) are one of the most common and penetrant genomic rearrangements observed in ASD, accounting for up to ~3% of cases. New advances in mouse and rat models have allowed for the development and utilization of clinically-relevant behavioral assays to measure sophisticated outcomes of social communication, fine grained motor skills, and learning and memory with neurophysiological outcomes such as spiking events, spectral power and sleep.

Objectives:

To examine clinically-relevant behavior, neuroanatomy by MRI, and neurophysiology by electroencephalographic (EEG) in our *Ube3a* deletion rats and an *Ube3a* overexpression mouse model system.

Methods: N/A

Results: We discovered delayed reflex development, altered social communication, gait abnormalities, and impaired learning and memory in the *Ube3a* deletion rat model of AS. We also discovered EEG characteristics that are translationally relevant and have been observed in AS and Dup15q clinics, such as abnormal levels of delta and beta power bands. We also discovered that profound neuroanatomical phenotypes.

Conclusion:

Our use of translational innovative outcome measures, like motor skills, social communication, EEG for seizures and power, touchscreen tasks, sleep physiology and motor skills, are required to test the utility of innovative drug designs (i.e. gene therapy, viral vector delivery and/or stem cells), as well as to validate other traditional medicinal therapies (i.e., diet, or pharmaceutics) that may be in the drug discovery pipeline by biotechnological and pharmaceutical companies. Funded by NINDS (R01NS097808) and FAST.

4:20 **192.003** EEG in Cognitive Tasks in Preclinical Models As Translational Biomarker

***J. Brigman**, University of New Mexico, Albuquerque, NM*

Background: There is a pressing need for translational tests of cognitive functioning that demonstrate consistent neurophysiological biomarkers across species. While preclinical studies provide numerous therapeutic targets for neuropsychiatric disorders, the failure to convert these to clinical treatments highlight that behavioral similarity alone is insufficient. Biomarkers of brain function are needed. As part of an ongoing project, we recently integrated tasks measuring specific Research Domain Criteria (RDoC) with electroencephalography (EEG) in mouse and human subjects to directly compare neural activity across species. Despite the procedural differences (e.g., training in touchscreens for mice, instructions and a joystick in humans), psychometric and neural biomarker signatures of performance were consistent across species.
Methods: Humans were tested in a variety of behavioral paradigms including the probabilistic learning task (PLT) progressive ratio breakpoint task (PRBT), and 5-choice continuous performance task (5C-CPT), while neural electroencephalogram (EEG) recording was conducted. Similarly, C57BL/6J mice performed touch-screen analogs of these paradigms while or dura-resting EEG-like signal was recorded for direct comparable analysis.
Results: During PLT performance we observed that frontal Reward Positivity scaled with the degree of positive prediction error, varying in strength according to probability ratio in both humans and mice. On the PRBT we observed parietal alpha power was elevated as both humans and mice neared their breakpoint. In the 5C-CPT, performance varied based on task difficulty in both humans and mice and post response EEG stimuli exhibit consistencies across species.
Discussion: We demonstrated the capability of utilizing identical methods for investigating rodent neuronal activity performing the same behavioral tasks available in rats and humans, in cognitive control, effortful motivation, and reward learning. Current studies will determine whether psychopharmacological challenges alter EEG signaling consistently across humans and rodents. These techniques provide important information regarding the validity rodent models to neural circuitry of behaviors relevant to psychiatry in addition to the likelihood of translating drug-induced changes in performance across species.

4:45 **192.004** Quantifying Preclinical and Clinical EEG Biomarkers in Neurodevelopmental Disorders

***M. Sidorov**, University of North Carolina, Chapel Hill, NC*

Successful clinical trials for neurodevelopmental disorders will require reliable biomarkers that are quantitative, biologically based, and linked to clinically meaningful deficits. Ideally, such biomarkers will also have face validity in animal models. We will describe quantitative EEG biomarkers for Angelman syndrome (AS), a neurodevelopmental disorder caused by loss of neuronal expression of the maternally inherited UBE3A gene. Symptoms of AS include intellectual disability, impaired speech and motor function, epilepsy, and disrupted sleep. We will discuss and evaluate three recently described quantitative EEG biomarkers in AS: enhanced delta rhythms, abnormal coherence, and disrupted sleep spindles. We anticipate that the use of these biomarkers will have value both in preclinical testing of compounds and in the eventual design of clinical trials.

Panel Session
Biomarkers (molecular, phenotypic, neurophysiological, etc)
193 - "Developmental Disconnections" in Infants at Risk for ASD
3:30 PM - 5:30 PM - Room: 524

Panel Chair: Shafali Jeste, *University of California, Los Angeles, Los Angeles, CA*

Discussant: Emily Jones, *Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom*

Converging evidence from genetics suggests that disruptions in the development of healthy neural circuits underlie and precede behavioral signs of autism spectrum disorder (ASD). Imaging and electrophysiological studies have quantified aberrant neural connectivity in children and adults with ASD, with a wide range of (and difficult to generalize) results owing to the heterogeneity of methods and populations studied. Examination of functional connectivity patterns in infants at risk for ASD, well before behavioral signs and confounding comorbidities emerge, can elucidate early brain changes that relate more directly to putative biological mechanisms. These findings can, in turn, inform more targeted studies of biomarkers of functional connectivity in childhood. Here, we present innovative approaches to the investigation of neural connectivity in infants at risk for ASD, through electroencephalography (EEG: Tran, Haartsen) and magnetic resonance imaging (MRI: Ciarrusta, Chen). In the context of these data that demonstrate atypical connectivity patterns both at rest and during social information processing in early infancy, we will discuss (Jones) methodological challenges and opportunities in infant connectivity studies, consider the generalizability of these findings, and share experiences from infant imaging consortia on the value of and next steps in large-scale studies of infant brain development in ASD.

3:30 **193.001** Atypical Brain Network Connectivity Proximal to Behavioral Symptom Onset in Toddlers with Autism Spectrum Disorders

*B. Chen[1,2], A. C. Linke[1], L. Olson[1,2], C. H. Fong[1], S. Reynolds[1], M. Kinnear[1], R. A. Mueller[1,2] and **I. Fishman**[1,2], (1)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (2)Joint Doctoral Program in Clinical Psychology, SDSU / UC San Diego, San Diego, CA*

Background: Behavioral signs of autism spectrum disorders (ASDs) appear in the first years of life; however, little is known about brain networks organization in ASDs during this critical developmental period, proximal to autism symptom onset. While there is evidence of early anatomical abnormalities in toddlers with ASDs, including increased cortical surface and brain volume, as well as extra-axial cerebrospinal fluid, less is known about functional network organization early in life in ASDs.
Objectives: To examine functional connectivity patterns in toddlers with (or suspected of having) ASD, utilizing multiband functional MRI data acquired during natural sleep. We hypothesized to find atypical maturational trajectories of network integration (strengthening connectivity within networks) and differentiation (decreasing connectivity between networks) in children with ASDs.

Methods: Participants were young children with ASDs (mean age: 28±7 months) and typically developing (TD) toddlers (26±7 months) continuously enrolling in the ongoing longitudinal study of early brain markers in ASDs. Clinical best estimates of ASD diagnoses were established based on DSM-5 criteria, and supported by the Autism Diagnostic Observation Schedule (ADOS-2), with final diagnoses confirmed longitudinally. The Mullen Scales of Early Learning and Vineland Adaptive Behavior Scales were administered to assess visual reception, motor, language, and social development. To date, T1-weighted anatomical MRI and fMRI data were acquired in 22 toddlers with ASDs and 22 TD toddlers during natural sleep. Group Independent Component Analysis (ICA) was applied to fMRI data, and after identifying 10 independent components (ICs) as non-artifact intrinsic functional connectivity networks (iFNs), mean time series were extracted from thresholded iFN masks and entered into a 10x10 pairwise correlation matrix, for each participant. Group differences in iFN connectivity were examined with two-sample t-tests applied to the correlation matrices.

Results: As expected, participants with ASDs showed delayed development across multiple behavioral domains including gross and fine motor skills, visual reception, receptive and expressive language, and socialization. Group comparisons of iFNs revealed significantly weaker connectivity between medial and lateral visual iFNs (p=0.03, FDR corrected), as well as significantly stronger connectivity between medial visual iFN and sensorimotor network (p=0.01, FDR corrected) in toddlers with ASDs. Connectivity between the medial and lateral visual RFNs was negatively correlated with age in ASD (r=-0.66) but not in TD (r=0.03) toddlers, with significant age by diagnosis interaction. In toddlers with ASDs, greater connectivity between visual and motor networks was correlated with greater symptom severity measured with ADOS (r=0.58, p=0.02) and with worse performance on the Mullen Early Learning Scales (r=-0.50, p=0.04).

Conclusions: These findings point to atypical functional connectivity implicating visual network in 1.5-3.5 years old children with ASDs, including weaker connectivity within visual networks, and stronger connectivity between visual and motor regions. The age-related decline in the connectivity between visual and other primary sensorimotor networks observed in ASDs between age 1.5 and 3.5 years, but not detected in TD children, suggests a maturational delay in network segregation in ASDs. This interpretation was supported by the data indicating that greater network segregation in toddlers with ASDs was associated with decreased symptoms and greater developmental scores.

Background: Behavioral signs of autism spectrum disorders (ASDs) appear in the first years of life; however, little is known about brain networks organization in ASDs during this critical developmental period, proximal to autism symptom onset. While there is evidence of early anatomical abnormalities in toddlers with ASDs, including increased cortical surface and brain volume, as well as extra-axial cerebrospinal fluid, less is known about functional network organization early in life in ASDs.
Objectives: To examine functional connectivity patterns in toddlers with (or suspected of having) ASD, utilizing multiband functional MRI data acquired during natural sleep. We hypothesized to find atypical maturational trajectories of network integration (strengthening connectivity

within networks) and differentiation (decreasing connectivity between networks) in children with ASDs.

Methods: Participants were young children with ASDs (mean age: 28±7 months) and typically developing (TD) toddlers (26±7 months) continuously enrolling in the ongoing longitudinal study of early brain markers in ASDs. This interpretation was supported by the data indicating that greater network segregation in toddlers with ASDs was associated with decreased symptoms and greater developmental scores.

3:55 **193.002** Functional Connectivity during Language Processing in Infants at Familial Risk for ASD

X. A. Tran[1]*, A. H. Dickinson*[1]*, N. M. McDonald*[2]*, M. Dapretto*[3] *and S. Jeste*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) is a disorder of connectivity, with ASD genes converging to disrupt neural development and cortical connectivity prenatally. Familial-risk infants, defined by having at least 1 older sibling with ASD, have increased risks for ASD and language delay (Messinger 2013). Neuroimaging studies have identified abnormal structural and functional connectivity in FR infants at 6 months that relate to future ASD symptoms (Shen 2017). No prior study has examined connectivity during language processing in familial-risk infants longitudinally throughout the first year of life.

Objectives: We asked if EEG connectivity, as measured by phase coherence, during language processing, (1) differentiates infants based on risk status and ASD symptoms during the first year of life (at 3-month, 6-month, 9-month, and 12-month), and (2) relates to 18-month language ability and ASD symptoms. We hypothesized that atypical connectivity during language processing is detectable at 3 months of age in infants who will have 18-month behavioral-concerns for ASD.

Methods: Participants included 49 familial-risk and 35 low-risk infants, who were divided into ASD-concern and No-concern groups based on their 18-month ADOS-T calibrated severity score (scores ≥ 4 are ASD-concern). 18-month groupings included 17 ASD-concern and 54 No-concern infants. EEG was acquired longitudinally (at 3, 6, 9, and 12-month) while infants listened passively to a continuous stream of syllables for 2.5 minutes (EGI 128 channels). EEG was collected using NetStation and filtered at 1.5-50 Hz. To maximally reduce artifacts, EEG data were cleaned using EEGLAB artifact subspace reconstruction, 1-model adaptive mixture independent component analysis, and transformed to current source density. Using newcrossf, phase coherence was calculated in the theta (4-6 Hz), alpha (6-12 Hz) and gamma (30-50 Hz) bands between 39 electrode pairs in putative language networks (Figure 1). Language ability and ASD symptoms were assessed at 18-month using Mullen Scales of Early Learning (MSEL), MacArthur-Bates Communicative Development Inventory (MCDI), the Vineland Adaptive Behavior Scales, and Autism Diagnostic Observation Schedule-Toddler Module (ADOS-T).

Results: All statistics for coherence analyses are provided in Table 1. Phase coherence differentiated ASD-concern from No-concern infants cross-sectionally at 3-month, 6-month, 9-month, and 12-month. Compared to ASD-concern infants, No-concern infants had higher phase coherence across theta, alpha and gamma bands in multiple frontal-posterior, frontal-temporal and frontal-central electrode pairs throughout the first year of life. At electrode pairs that differentiated risk-groups, greater phase coherence predicted greater language ability and reduced ASD symptoms at 18-month.

Conclusions: Neural connectivity during auditory language processing in early infancy likely supports subsequent language development. This study documents the earliest manifestation of altered connectivity during language processing in familial-risk infants. Hypoconnectivity during language processing could serve as an early marker of atypical neurodevelopmental trajectories. Ongoing work with this study will include longitudinal modelling of 3-month through 12-month timepoints to examine potential divergent developmental trajectories in infants with atypical development.

4:20 **193.003** Atypical Cortico-Cerebellar Connectivity in Newborn Infants at Risk of Developing ASD

J. Ciarrusta[1]*, J. Ó Muircheartaigh*[2]*, R. Dimitrova*[3]*, D. Batalle*[1]*, L. Cordero-Grande*[3]*, A. N. Price*[3]*, E. Hughes*[3]*, M. J. Kangas*[4]*, A. Javed*[4]*, D. G. Murphy*[5]*, A. D. Edwards*[3]*, T. Arichi*[6] *and G. M. McAlonan*[7]*, (1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Neuroimaging, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Centre for the Developing Brain, Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, (4)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Imaging Science & Biomedical Engineering, King's College London, London, United Kingdom, (7)NIHR-Biomedical Research*

Centre for Mental Health at the Institute of Psychiatry, Psychology and Neuroscience, South London and Maudsley Foundation NHS Trust, London, United Kingdom

Background:
While atypical functional connectivity in resting state networks has been widely reported in adults with ASD, little attention has been directed to functional activity in the cerebellum, which communicates with somatosensory, executive control network and salience networks (Habas, 2009). Discrepancies in the limited cortico-cerebellar connectivity studies in adults further call for a better understanding of possible atypical developmental of cortico-cerebellar connectivity (Crippa, 2016). Furthermore, adults with social anxiety disorder show decreased functional connectivity between the cerebellum and the executive control network (Yuan 2017), suggesting cortico-cerebellar connectivity might be involved in atypical social behavior observed in ASD.

Objectives:

Here, we used Regional Homogeneity (ReHo) and seed based correlation analysis to quantify functional connectivity in the cerebellum and the cortico-cerebellar connectivity at 'rest' (fMRI) in neonates with (R+) and without (R-) an established risk factor for ASD. We hypothesized that there would be a group difference on the maturation of intra-cerebellar and cortico-cerebellar functional connectivity.

Methods:

High temporal resolution fMRI during natural sleep was acquired in a Philips 3T Scanner from 18 R+ and 18 R- neonates within the first 4 weeks of life [R+ mean age 42.68 weeks post-menstrual age (PMA); R- mean age 42.24 weeks PMA]. Data pre-processing was implemented in FSL (www.fmrib.ox.ac.uk/fsl), with non-linear spatial normalization into an age-appropriate template space (http://brain-development.org/brain-atlases/multi-structural-neonatal-brain-atlas/). Voxel-wise regional homogeneity (ReHo) values were extracted using AFNI 3dReHo for 27 nearest neighbors per voxel. Unpaired t-tests with permutation testing was used to compare the interaction between age and regional homogeneity maps in the cerebellum between groups with false discovery rate (FDR) correction for multiple comparisons. Next, we calculated the correlation between the mean timeseries of the cerebellum with each cortical voxel for each subject and z-transformed it. The same permutation analysis applied for ReHo was used to compare the cortico-cerebellar z-maps between groups.

Results:

We found an interaction effect of ReHo and age in the cerebellum: ReHo increased with age in the R- group, but it did not in the R+ group (Figure 1). While strongest connectivity with the cerebellum was observed in the somatosensory motor regions, significant differences between groups were observed in the superior parietal and dorsolateral prefrontal cortex in the left hemisphere. R+ had higher functional connectivity between the cerebellum and regions involved in executive control network (Figure 2).

Conclusions:

Our results show infants at risk of developing ASD might be born with and proceed with an atypical maturation of cortico-cerebellar connectivity. Atypical connectivity might be particularly vulnerable in networks that have been previously associated to social anxiety.

4:45 **193.004** Diminished Social Network Connectivity in Infancy Predicts Social Communication in Toddlers with High Likelihood of Autism

R. Haartsen[1], *M. H. Johnson*[2], *T. Charman*[3] *and E. J. Jones*[4], *(1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom of Great Britain and Northern Ireland, (2)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom*

Background:
Social difficulties form one of the core features of Autism Spectrum Disorder (ASD), and could be associated with variability during early social brain development. Prospective studies examining sensitive measures of social brain development are critical to further examine this. One promising candidate is theta-band EEG power; greater theta responses to faces compared to objects has been related to communication improvement in toddlers with ASD (Dawson et al., 2012). It remains unknown how infant EEG theta connectivity is modulated by social context. Moreover, it is unclear whether theta connectivity modulations relate to likelihood and diagnostic outcome of ASD, or social-communication skills.

Objectives:

The present study is the first to examine a) how infant theta connectivity is modulated by social context, and b) how these socially elicited responses associate with familial likelihood of ASD, diagnostic outcome, and social-communication abilities during toddlerhood.

Methods:

Infants viewed videos of women singing nursery rhymes and spinning toys during EEG recording at 14 months of age. EEG theta connectivity was calculated using the debiased weighted phase lag index for 4 – 5 Hz. Diagnostic outcome and communication abilities were assessed at 36 months of age using parental interviews, questionnaires, and direct observations. The final sample with clean EEG data included 17 infants with low (LL), and 51 infants with high familial likelihood for ASD (HL); 27 infants showed typical development (HL-TD), 8 infants met criteria for ASD (HL-ASD), and 16 infants showed atypical development at 36 months (HL-Atyp).

We used global connectivity (averaged across all channel pairs) and Network Based Statistics to compare whole brain and connection-level differences between social and non-social conditions within the different likelihood and outcome groups. Spearman's correlations were used to examine associations between theta modulations and communication skills using the Socialization and Communication subscales of the Vineland Adaptive Behaviour Scales-II.

Results:

Whole brain connectivity displayed significant increases during social compared to non-social stimuli ($p < .0001$, $\eta_p^2 = .233$). This difference in whole-brain theta connectivity between social and non-social stimuli was greater in the LL group than the HL group ($p = .011$, $\eta_p^2 = .093$, Fig. 1A), whereas this difference was similar between the HL diagnostic outcome groups ($p = .593$, $\eta_p^2 = .022$).

Further, network analyses showed stronger socially elicited responses for connections between parietal and occipital areas in the LL group;

connectivity in this LL network was significantly stronger than in the HL group ($p < .0001$, $\eta_p^2 = .180$), who showed modulation by social content across a different fronto-parietal network (Fig. 1B).

Finally, individual differences in connectivity within the LL network were associated with later social and communication skills in the whole group of infants (*rho's* ≥ .26, *p's* ≤ .033, Fig. 2).

Conclusions:

Theta connectivity is a promising measure of social brain development in infancy. Alterations in connectivity patterns are present in infants with an older sibling with autism, and relate to later developmental outcomes. Early altered connectivity may reflect atypical interactive specialisation of the social brain in the context of increased likelihood of developmental atypicalities.

Panel Session
Interventions - Non-pharmacologic - School-Age, Adolescent, Adult
194 - Social Skills Training in Autism: Yesterday's Challenges and Tomorrow's Solutions
3:30 PM - 5:30 PM - Room: 516ABC

Panel Chair: Sven Bolte, *Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Discussant: Elizabeth Laugeson, *Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Social skills Training (SST) is a widely used intervention technique in autism practice. Latest research has consistently shown moderate effects in large randomized controlled trials. Still, a multitude of questions remain around SST's effectiveness and efficiency. In addition, self-advocates have been critical of SST. This session provides both a state-of-the-art overview of SST, and insights into the latest developments in addressing challenges and the unknowns of SST in autism. We present new research findings and discuss issues of personalization of SST, its generalization, and cross-cultural validity, as well as the need to redefine outcomes, and optimize administration and dosage.

3:30 **194.001** Fifteen Years of Social Skills Group Training "Kontakt"© - Heading for Precision Support, Dosage Optimization and Long-Term Follow-up

***S. Bolte**, Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: KONTAKT(c) is a manualized social skills group program for children and adolescents with ASD aged 8-17 years in the normative IQ range. It uses principles of cognitive behavior therapy, psychoeducation, behavioral activation, cognitive training, and observational learning to increase social communication skills, conflict management and prevention, coping strategies, self-confidence, and daily functional skills. The teaching formats include individual goal identification, group discussions and activities, social and role-play, emotion-processing training, and homework assignments based on functional analysis.

Objectives: To summarize quantitative and qualitative research on KONTAKT from the last 15 years across three countries (Germany, Sweden, Australia), current analyses on genetic and psychiatric comorbidity moderators of the effects of training, and planned register-based long-term follow-up of study participants.

Methods: Two pilot studies in Sweden and Germany were conducted, followed by largest (pragmatic) randomized controlled trial (RCT) in ASD ever on 12 and 24 sessions of KONTAKT against standard care across 13 centers [NCT01854346] (n=296 [12 sessions], n=50 [24 sessions]) in Sweden. Saliva samples were collected from the RCT participants for Copy Number Variations (CNV) analyses . A qualitative responder analysis was also carried-out. Subgroup analyses were conducted for KONTAKTs efficacy in children, adolescents, girls and boys. Further, the potential effects of other mediators and moderators were examined, such as IQ, language level, medication, and psychiatric comorbidity.

Results: The RCT showed that effect sizes for social communication and adaptive functioning improvement were large for participants in the 24-session program (d=0.76-0.82) and moderate for female and adolescent participants in the 12-session program (d =0.33-0.40). Aside of age and sex, participant characteristics that were associated with KONTAKT's efficacy were psychiatric comorbidity and the size of CNVs: Clients with additional anxious-depressed symptoms responded better to KONTAKT, while those carrying large CNVs responded poorer. Extensive qualitative studies of KONTAKT showed a multitude of individual progress not covered by the outcome measures used in the RCT, indicating benefits even in quantitative "non-responders".

Conclusions: These results indicate, for the first time, a substantial dose-response effect for social skills group training in autism, which implies that service providers can reach better results by optimizing the length of intervention. Importantly, we found that age, sex, psychiatric comorbidity, and genomic variation impact on KONTAKT effects, endorsing that personalized training decisions might be meaningful.

3:55 **194.002** Cross-Cultural Adaptation to Australia of the Kontakt© Social Skills Group Training Program for Youth with Autism Spectrum Disorder: A Pilot Study

***S. J. Girdler**[1], B. Afsharnejad[2], M. Falkmer[3], M. H. Black[1], T. Alach[4], C. Coco[5] and S. Bolte[6], (1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (2)Autism Research Team, Telethon Kids Institute, Perth, Australia, (3)Curtin University, Bentley, Australia, (4)Autism Specific Early Learning and Care Centre, Bedford, Australia, (5)Karolinska Institutet, Stockholm, Sweden, (6)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: Social skills group training (SSGT) has shown efficacy in remediating the social communication and interaction challenges faced by adolescents with Autism Spectrum Disorder (ASD). KONTAKT, a SSGT for adolescents with ASD, has demonstrated efficacy in young people with ASD in Sweden and Germany, however its cross-cultural feasibility and efficacy in an Australian context remains unknown

Objectives: This pilot study investigated the feasibility and cultural validity of KONTAKT in improving the social skills of Australian adolescents with ASD

Methods: The KONTAKT manual was translated from Swedish to English and subsequently delivered to 16 adolescents with ASD over 16 one and a half hour sessions. The 16 adolescents formed 2 groups of 8 participants, with each group facilitated by 2 trained therapists from the Autism Association of Western Australia. Using a mix methodology design the cross-cultural feasibility and preliminary efficacy of the 16 week variant of KONTAKT was evaluated. A pre-test post-test design evaluated changes in outcomes including socially meaningful goals, ASD related traits, quality of life, emotion recognition and social anxiety, loneliness via adolescent self-report, parent proxy and blind expert rating at 3 time points: baseline, post intervention and at 3-month follow up. Random effects regression model (linear mixed model) examined changes dependent variables. Focus groups were conducted with adolescents and their parents, and KONTAKT trainers eliciting data in relation to the feasibility and outcomes of the program.

Results: All 16 participants completed the program to the follow up. KONTAKT resulted in most adolescents achieving their self-reported socially meaningful goal ($p<0.001$) and a significant reduction of autism related traits as rated by parents on the SRS-2 ($p<0.05$), with the effect size (Cohen's d) ranging from 0.3 to 0.8. Adolescents with ASD also demonstrated improvements in quality of life. Qualitative data suggested that adolescents, parents and trainers were generally satisfied with the KONTAKT program, but identified several areas for improvement particularly in relation to group activities and homework.

Conclusions: Findings indicate that KONTAKT may support Australian adolescents with ASD in reducing their autism related traits and achieving their socially meaningful goals. The pilot study resulted in finalization of KONTAKT Australia in preparation for evaluation of its efficacy in a randomised controlled trial. This study will be designed to control for the potentially confounding effect of exposure to a social context through the use of an active control group and will undertake a cost utility analysis. Findings will inform our understanding of both the efficacy of SSGT interventions in adolescents with ASD and the relationship between dose and response (number of sessions and changes in outcomes) of social skills training programs. (ANZCTR: ACTRN12617001117303, ClinicalTrials.gov: NCT03294668)

4:20 **194.003** A Single-Blind RCT of an Evidence-Based Social Skills Intervention for Youth with ASD: Effects on Behavioral and Neural Indices of Social Functioning

M. D. Lerner[1], *E. Kang*[2], *T. Rosen*[2], *R. Weber*[3], *C. M. Keifer*[2] *and A. H. Gerber*[2], *(1)Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY, (3)Stony Brook University, Centereach, NY*

Background: While social skills interventions (SSIs) for youth with autism spectrum disorder (ASD) evince modest effects, it is not clear whether widely-reported parent-report effects of SSIs represent true change, or parent expectations for change (Gates et al., 2017). Furthermore, no study has used rigorous component-control designs to examine whether less subjectively-determined effects are specific to particular elements of those SSIs. The SSI socio-dramatic affective-relational intervention (SDARI; Lerner et al., 2011) uses specific game-like activities putatively designed to provide opportunities for intensive practice of social competence elements (e.g., interpreting tone of voice) in a supportive environment. While SDARI has shown effects on parent-report social skills, observed social behavior, peer sociometrics, and neural indices of social perception (e.g., Lerner & Mikami, 2012; Kang et al., 2017), it is unknown whether SDARI-specific activities (versus nonspecific supportive environment) or parent expectations are responsible for these effects.
Objectives: To examine whether SDARI exerts unique effects on social behavior, peer regard, and neural metrics of social perception. To examine whether effects on parent-report are attributable to expectancy effects.

Methods: 55 youth (M_{age}=12.40, SD_{age}=2.92; 40 male), IQ≥70 and ADOS-2 (Lord et al., 2012)-confirmed diagnoses, were randomly assigned to SDARI or an attention control (8 groups total; 1.5 hours/week, 10 week), which followed a schedule identical to SDARI but used structured recreational activities not inherently social (e.g. art projects). As both conditions were likely to produce some benefit, participants and parents were held unaware of condition. Parents completed a questionnaire battery (e.g., SSIS; Gresham et al., 2010) and indicated the group to which they believed their child had been assigned. Participants completed assessments including EEG-indexed evaluation of social processing (e.g., N170 ERP latency to face; N100 amplitude to voice; Lerner et al., 2013). Participants provided sociometric ratings of one another during the first and final sessions; their prosocial behaviors in unstructured free play for 20 minutes during the middle of each session were coded (Bauminger, 2002) by reliable (ICC(1,2) = .829) raters blinded to time and condition. Generalized Estimating Equations (accounting for nesting within groups) were used.

Results: Parent-report effects on social skills were attributable to the condition to which parents believed their child was assigned, not actual condition (Wald's X^2=6.256, p<.05; Figure 1A). The SDARI group showed a relative acceleration in N170 latency and increase in N100 amplitude (both X^2 >6.00, p≤ .05; Figure 1B-C). While those in SDARI became reciprocated friends more quickly, the attention control caught up (X^2=6.522, p<.05; Figure 1D). The same pattern was seen for interactions with peers (SDARI: X^2=35.87, p<.001; condition*time: X^2=4.87, p<.05).

Conclusions: This blinded RCT supports specificity of SDARI activities on neural indices of social processing, sociometrics, and observer-rated social behavior, but suggests the latter may be accomplished – albeit more slowly – without SDARI activities, a pattern found in a previous RCT (Lerner & Mikami, 2012). It also suggests that parent-report effects are attributable to expectations of condition, not SDARI-specific. Future work should employ such designs to better elucidate what aspects of other SSIs are responsible for their effects.

4:45 **194.004** Parent-Mediation and Teacher-Facilitation As Mechanisms of Change in Social Skills Training: Treatment Outcomes for the PEERS® for Adolescents Intervention

E. A. Laugeson, *Y. S. S. Lograsso, M. Jolliffe and N. E. Rosen, Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background:
Impaired social skills are known to negatively impact individuals with ASD across the lifespan. While social skills training is a common treatment method, few evidence-based interventions exist to improve social functioning for adolescents on the spectrum (Reichow & Volkmar 2010). Parent-mediated interventions have shown promise in teaching social skills to adolescents with ASD (Laugeson et al., 2009; 2012; Van Hecke et al. 2013; Schohl et al. 2013), and teacher-facilitated interventions have also yielded encouraging findings (Laugeson et al. 2014). While parent and teacher involvement are thought to be important mechanisms of change in social skills training, little is known about the differences in treatment outcomes across these two mechanisms.

Objectives:

The purpose of this study is to: (1) examine changes in social functioning following parent-mediated and teacher-facilitated social skills interventions for adolescents with ASD; and (2) examine differences in treatment outcomes when parents or teachers are included in treatment.

Methods:

Participants included 290 adolescents with ASD (76% male) ranging in age from 11-19 (*M*=14.13; *SD*=1.83). Participants received either parent-mediated (*n*=205) or teacher-facilitated (*n*=85) social skills instruction for 14-weeks using the PEERS® curriculum (Laugeson & Frankel 2010; Laugeson, 2014). Skills focusing on friendship development were targeted. Treatment outcome was measured across the two groups (parent-mediated v. teacher-facilitated) using a battery of standardized and criterion-based measures including the Social Responsiveness Scale-Second Edition (SRS-2: Constantino 2012), Social Skills Improvement System (SSIS; Gresham & Elliott 2008), Test of Adolescent Social Skills Knowledge (TASSK; Laugeson 204), and Quality of Socialization Questionnaire-Adolescent (QSQ-A; Laugeson 2014).

Results:

Paired sample T-tests examining outcomes in the parent-mediated program revealed significant improvement in T-scores on the SRS-2 Total Subscale (pre-test: *M*=77.55, *SD*=9.358; post-test: *M*=68.91, *SD*=10.475; *t*(205)=12.22, *p*<0.01), standard scores on the SSIS Social Skills Subscale SIS (pre-test: *M*=78.34, *SD*=12.68; post-test: *M*=85.75, *SD*=11.67; *t*(205)=10.51, *p*<0.01), social skills knowledge on the TASSK (pre-test: *M*=13.45, *SD*=3.188; post-test: *M*=22.22, *SD*=4.376; *t*(205)=28.504, *p*<0.01), and social engagement on the QSQ-A (pre-test: *M*=2.709, *SD*=3.233; post-test: *M*=5.126, *SD*=4.913; *t*(205)=7.214, *p*<0.01).

Paired sample T-tests examining outcomes in the teacher-facilitated program revealed significant improvement in T-scores on the SRS-2 Total Subscale (pre-test: *M*=77.55, *SD*=9.358; post-test: *M*=68.91, *SD*=10.475; *t*(85)=3.476, *p*<0.01), and standard scores on the SSIS Social Skills Subscale (pre-test: *M*=79.34, *SD*=12.174; post-test: *M*=83.55, *SD*=14.209; *t*(85)=3.555, *p*<0.01), and social skills knowledge on the TASSK (pre-test: *M*=13.45, *SD*=4.376; post-test: *M*=22.22, *SD*=4.376; *t*(85)=3.476, *p*<0.01). Significant improvements were not observed on the QSQ-A.

In order to compare differences in treatment outcome across the two groups (parent-mediated v. teacher-facilitated), independent samples T-tests were conducted. Significant differences in change scores were observed across the groups on the SRS-Total Subscale (parent-mediated: *M*=8.646, *SD*=10.156; teacher-facilitated: *M*=3.069, *SD*=8.190; *t*(195.72)=4.514, *p*<0.01), SSIS Social Skills Subscale (parent-mediated: *M*=7.408, *SD*=10.116; teacher-facilitated: *M*=4.209, *SD*=10.980; *t*(290)=2.401, *p*<0.05), social skills knowledge on the TASSK (parent-mediated: *M*=8.777, *SD*=4.419; teacher-facilitated: *M*=4.605, *SD*=3.692; *t*(290)=7.702, *p*<0.01), and social engagement on the QSQ-A (parent-mediated: *M*=2.418, *SD*=4.81; teacher-facilitated: *M*=-0.093, *SD*=3.154; *t*(237.42)=5.259, *p*<0.01).

Conclusions:

Findings reveal that while both program are efficacious, parent-mediation, in comparison to teacher-facilitation, is a greater mechanism of change in social skills training using the PEERS® curriculum.

Panel Session
Medical and Psychiatric Comorbidity
195 - Where Do We Go from Here? Learning How to Prevent Suicide in Partnership with Autistic People and Their Allies.
3:30 PM - 5:30 PM - Room: 518

Panel Chair: Sarah Cassidy, *School of Psychology, University of Nottingham, Nottingham, United Kingdom*

Discussant: Jacqui Rodgers, *Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Autistic people are at increased risk of suicide compared to the general population. This year's INSAR policy brief thus identified the top 10 research and policy priorities to prevent suicide in autism, in partnership with autistic people and their allies. This panel will discuss the findings and implications of this policy brief, in the context of current international suicide in autism research. First, a reflection from a lived experience perspective on the policy brief findings, and importance of researchers working in partnership with autistic people and their allies to decide priorities which will affect their lives. Second, the latest international research findings in relation to effectively understanding, identifying and managing risk of self-harm and suicide in autistic people will be discussed. Third, we will discuss where we go from here to improve our understanding of suicide prevention in autism.

3:30 **195.001** Measurement Properties of the Suicide Behaviours Questionnaire - Revised in Autistic Adults.

S. A. Cassidy[1], *L. Bradley*[2], *R. Shaw*[3], *E. Bowen*[4], *M. Glod*[5], *S. Baron-Cohen*[6] *and J. Rodgers*[5], *(1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)Coventry University, Coventry, United Kingdom, (3)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom, (4)University of Worcester, Worcester, United Kingdom, (5)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: The Mental Health in Autism project (MHAutism) aims to develop a new suicidality assessment tool for autistic adults – a group at high risk for dying by suicide. Our systematic review found no studies exploring suicidality in autistic adults had yet used a tool with evidence of validity, and no suicidality assessment tool had yet been developed for this group. However, we identified the Suicidal Behaviours Questionnaire – Revised (SBQ-R) as a promising candidate tool to adapt for autistic adults. The current study explores the appropriateness and psychometric properties of the SBQ-R in autistic compared to general population adults, to inform future adaptations.

Objectives: First, to explore whether the SBQ-R similarly captures the same latent construct (suicidality) in autistic compared to general population adults. Second, to explore how autistic adults interpret and respond to the items of SBQ-R.

Methods: First, 188 autistic adults (76 male) and 183 general population adults (62 male) completed the SBQ-R online. Multi-group factorial invariance (MFI) analysis compared the structural equivalence of the SBQ-R between the groups. Cognitive interviews subsequently explored how a sub-group (*n* = 15) of autistic adults interpreted and responded to the items of the SBQ-R.

Results: MFI analysis of the online survey data found evidence for configural but not metric invariance of the SBQ-R, with significantly different factor loadings between groups for items three (communication of suicide threat to others) and four (future suicidal intent) of the questionnaire.

Consistent with these findings, cognitive interviews revealed different interpretation of questions requiring abstract future thinking, social and communication skills, and absence of items which captured the unique presentation of suicidality in autism.

Conclusions: Findings suggest that autistic adults attribute a different meaning to some items on the SBQ-R compared to general population adults, and absence of items which capture the unique presentation of suicidality in autism. These results will be used to adapt the SBQ-R to better capture suicidality in autistic adults.

3:55 **195.002** "Where Do We Go from Here?" Identifying the Top 10 Priorities to Prevent Suicide in Partnership with Autistic People.

***J. Adams**, Flow Observatorium, Portsmouth, United Kingdom*

Background: Traditionally, priorities for future research were not decided by those affected by research, which resulted in a lack of research relevant to the day to day lives of autistic people. To address this, partnerships between autistic people and their allies are being developed, to ensure that autistic people have a strong voice in the direction of future research. One example of this new form of partnership, is INSAR's 2019 policy brief, which aims to identify the top 10 research and policy priorities to prevent suicide in partnership with autistic people and their allies.
Objectives: To provide a reflection, as an autistic person with lived experience, on the development of participatory research, the process of the INSAR policy brief, and the top 10 priorities identified in partnership with autistic people.

Methods: First, a summit, with equal representation of autistic, researcher, charity and service provider perspectives, discussed and identified a range of research and policy priorities to prevent suicide in autism. Second, an online survey, with equal weighted representation of autistic, researcher, charity, service provider and policy maker perspectives, prioritised and refined this longer list of priorities for discussion at a 2-day meeting. Third, the INSAR policy brief meeting brought together equal representation of these groups to identify the top 10 research and policy priorities to prevent suicide in autistic people.

Results: The top 10 priorities for future research and policy will be identified and discussed at the INSAR policy brief meeting, on the 4th and 5th April 2019, prior to presentation in this panel at the INSAR 2019 meeting. I shall reflect on the overall process and findings, as an autistic person with lived experience of the issues at hand.

Conclusions: Research which positively affects the lives of autistic people can only be achieved in close partnership between autistic people and their allies. It is important that we learn from examples of participatory working, such as this INSAR policy brief, to ensure that autistic people have a strong voice in the direction of future international research and public policy. This will help ensure that autism research and policy initiatives are useful to autistic people.

4:20 **195.003** Screening for Suicide Risk in Children with Autism and Related Disabilities in a Pediatric Autism Center.

***P. H. Lipkin**[1], S. Rybczynski[2], T. Ryan[3] and H. C. Wilcox[4], (1)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD, (2)Kennedy Krieger Institute, Baltimore, MD, (3)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD*

Background: Suicide thoughts and behaviors are reported at high rates in people with autism spectrum disorder (ASD). With high rates of suicide in the general population, suicide risk screening has been promoted during medical visits to US health care facilities by The Joint Commission since 2016.
Objectives: Determine suicide risk in children with ASD seen during medical visits using a suicide risk screening instrument at a specialty developmental medical center; and examine clinical characteristics of those with screening-identified suicide risk.

Methods: Suicide risk screening was performed on children ages 8 to 17 years seen for a medical visit at the Center for Autism and Related Disorders at the Kennedy Krieger Institute, a specialty children's developmental health facility, as part of an institutional quality improvement project over five months. The "Ask Suicide Screening Questions" (ASQ) was completed by nursing staff through child or parent/guardian interview before seeing a physician. Screening results, demographics, and clinical characteristics of those with ASD and identified suicide risk were analyzed, including past and current ideation and attempts, associated mental health diagnoses, therapies, medications, and family history of suicide.

Results: There were 775 children eligible for screening between August 2017 and January 2018. 542 were screened; 30% (233) eligible declined. 58 (10.7%) children demonstrated suicidal risk. Risk was two-fold higher in white children. 48 (8.9%) had confirmed or probable ASD diagnosis (73% male; 71% white; median age 12 years [range 8-17]). Of those with ASD screening at suicide risk, 40 (83%) were child-completed, 8 (17%) by the parent /guardian.

On the ASQ questions, 27 (56%) of the 48 children with ASD wished they were dead in the past few weeks, 16 (33%) thought they or family would be better off if they were dead, 17 (35%) had suicide thoughts within the past week, and 22 (46%) reported trying to kill themselves. Five (6%) were actively suicidal at screening; one was sent to the emergency department. None required hospital admission.

Chart review indicated that 44 (92 %) of the children with ASD who screened at risk had psychiatric comorbidities, with 15 (31%) having one disorder and 29 (60%) two or more. 35 (73%) had a history of ADHD, 28 (58%) anxiety, and 15 (31%) depression. Four (8%) had family history of suicide. They had high rates of mental health treatment (39; 81%), with 35 (73%) receiving psychiatric care and 29 (60%) psychotherapy. 40 children (83%) were currently treated with psychotropic medication, with 38% (18) taking one and 46% (22) two or more. 21 (44%) received an SSRI, 20 (42%) stimulant, and 12 (25%) antipsychotic medication.

Conclusions: Suicide risk screening in children with ASD at a specialty medical center demonstrates that suicide thoughts and attempts are common. Those with suicide risk have high rates of psychiatric comorbidity and are commonly treated with medication and psychotherapy. Children with ASD seen in specialty centers, particularly those receiving mental health treatments, are at high risk and should be screened for suicidal behavior as part of best clinical practice.

4:45 **195.004** The Phenomenology of Non-Suicidal Self-Injury in Autistic Adults.

***A. E. Robertson**[1], L. Bradley[1], R. Shaw[2], M. Pelton[1], B. B. Maddox[3], S. W. White[4], A. T. Wieckowski[5] and S. A. Cassidy[6], (1)Coventry University, Coventry, United Kingdom, (2)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom, (3)University of Pennsylvania, Philadelphia,*

PA, (4)Psychology, The University of Alabama, Tuscaloosa, AL, (5)Western Psychiatric Institute and Clinic, University of Pittsburgh Medical Center, Pittsburgh, PA, (6)School of Psychology, University of Nottingham, Nottingham, United Kingdom

Background:
Non-suicidal self-injury (NSSI) is defined as socially unsanctioned harming of the body without suicidal intent. Two studies have shown increased rates of NSSI in autistic (50-65%) compared to non-autistic adults (5-30%), and similar phenomenology of NSSI in a small sample of autistic and non-autistic adults (*n*=42). Larger scale studies are needed to confirm similarities and differences in NSSI behaviour between autistic and non-autistic adults, to inform new assessment and treatment strategies for autistic people. As many autistic adults are currently undiagnosed, and mental health problems are the most common presenting concern prior to being diagnosed autistic, it is important to include adults who self-identify as autistic but have not yet been formally diagnosed.

Objectives:

To compare the phenomenology (methods, frequency, severity, functions, and initial motivations) of NSSI between autistic, self-identified autistic, and non-autistic adults.

Methods:

An online cross-sectional survey in the UK and USA, measuring NSSI (Non-Suicidal Self-Injury – Assessment Tool; NSSI-AT), in: 1) *n*=132 autistic adults (UK), 2) *n*=56 self-identified autistic adults (UK), 3) *n*=57 non-autistic adults (general population) (UK), and 4) *n*=257 non-autistic adults (undergraduate students) (US).

Results:

Rates of NSSI differed across the samples, with more autistic adults (66.5%) and self-identified autistic adults (70.4%) endorsing NSSI than UK (29.6%) and US (20.5%) non-autistic adults. Autistic adults reported significantly more episodes of NSSI across their lifetime than non-autistic UK [$t(187) = 4.87$, $p<.001$] and non-autistic US adults [$t(288.1) = 11.28$, $p<.001$], but not self-identified autistic adults. There were also significant differences in certain self-reported forms, functions, motivations and wound locations of NSSI in autistic compared to non-autistic adults. Conversely, there were no significant differences – with the exception of one item – between autistic and self-identified autistic adults. Autistic adults also reported being significantly more likely to injure themselves in the future than non-autistic adults [UK: $t(186) = 5.27$, $p<.001$; US: $t(387) = 8.82$, $p<.001$], but not self-identified autistic adults. Overall, the endorsement of NSSI-AT items was very similar between autistic and self-identified autistic adults (Table 1).

Conclusions:

We compared the phenomenology of NSSI behaviour in a large sample of autistic, self-identified autistic, and non-autistic adults. Autistic adults reported a wider range of forms and functions of NSSI, different initial motivations for NSSI, reported injuring more parts of their body, a higher number of NSSI episodes in their lifetime, and increased likelihood of future self-injury, compared to two samples of non-autistic adults. Interestingly, the phenomenology of NSSI was very similar between the autistic and self-identified autistic group. Our results have important implications for clinical practice, as there is very little awareness of NSSI in autistic people, as traditionally defined in the general population. Self-identified autistic adults (i.e. those who identify as autistic but do not have a diagnosis) are also a high-risk group for NSSI, and further research is needed to explore their specific needs.

Panel Session
Medical and Psychiatric Comorbidity
196 - Sleep, Circadian Neuroscience, and Autism across the Lifespan
3:30 PM - 5:30 PM - Room: 517B

Panel Chair: Beth Malow, *Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN*

The theme of this panel is to explore the relationship of sleep and circadian neuroscience to autism in children, adolescents, and adults. The session will begin with the basic science of sleep and circadian rhythms, followed by genetic contributors. Clinical aspects and behavioral and pharmacological interventions will then be discussed.

3:30 **196.001** The Circadian Timekeeping System As a Window into Neurodevelopmental Disorders

***J. Lipton**, Boston Children's Hospital, Harvard Medical School, Boston, MA*

Sleep is a ubiquitous animal behavior that still remains a fundamental mystery. Among the least understood aspects of sleep is that its expression and architecture are highly regulated during animal development. Sleep is crucial for learning and memory, mood regulation, and metabolic health. It is not surprising then that sleep dysfunction is particularly common in children with neurodevelopmental disorders including autism spectrum disorders (ASD). Sleep is regulated by the combined influences of a homeostatic mechanism and the circadian clock. The clock is a multi-scaled biological timekeeping system that synchronizes gene expression, physiology, metabolism, and behavior with the 24 hour oscillations of the light/dark cycle.
There is an abundance of evidence from both the clinic and animal models that suggests a strong interplay between circadian rhythms and ASDs, however the mechanisms remain an area of active inquiry. I will review the molecular and cellular biology of the circadian clock and its links to animal and clinical models of ASD. I will review how the biology underlying syndromic disorders related to ASD such as Tuberous Sclerosis Complex, Fragile X Syndrome, and Angelman's syndrome is intimately intertwined with circadian biology. I will suggest that many ASDs (and related disorders) are, at a fundamental level, 'rhythm-opathies'.

The nexus between circadian clocks, sleep, and ASD is a new and important frontier that will lead to new targets and new therapies.

3:55 **196.002** Genetic Mechanisms Connecting Autism with Sleep & Circadian Rhythms

***O. Veatch**, University of Pennsylvania School of Medicine, Philadelphia, PA*

Sleep and circadian rhythm disorders are common in individuals with ASD. Disturbed sleep is shown to exacerbate core symptoms of ASD. Sleep problems may also intensify expression of other serious ASD comorbidities, such as epilepsy. Sleep has strong, neuronal-specific effects on the function of molecular, cellular and network mechanisms of neuronal plasticity. Further, studies in model systems indicate that sufficient sleep promotes proper neurodevelopment. In addition, mistimed sleep (i.e. mismatch between endogenous circadian rhythms and preferred sleep/wake schedule) is associated with a number of negative health outcomes and has been observed to disrupt physiological rhythms and circadian regulation of the transcriptome. Given the observations that disturbed sleep relates to more severe symptoms in ASD and that sleep is important to neuroplasticity, it is likely there is a crucial window during neurodevelopment where the quality of sleep has a lasting impact on neurological function. As such, the need for effective treatments for sleep disorders in ASD is profound. Understanding the causes and consequences of sleep disturbances in children with ASD is an important step toward mitigating these symptoms. It is possible that ASD symptoms drive disturbed sleep or that expression of ASD symptoms with comorbid sleep disturbances are modified by convergent genetic risk factors. Notably, the known biological functions for recurrently implicated genes in ASD suggest involvement of convergent molecular mechanisms. Evidence also indicates many of these convergent mechanisms overlap with those associated with risk for sleep disorders and expression of circadian rhythms. This suggests that pleiotropic genetic effects contribute to sleep and/or circadian disorders in some individuals with ASD. Understanding the genetic architecture underlying the relationship between ASD and expression of sleep and circadian disturbances may provide evidence useful toward optimizing more effective, personalized treatments in this population. This presentation will offer a broad overview of key findings from genetic studies of ASD, sleep traits, and circadian rhythm regulation highlighting shared genetic mechanisms that may underlie expression of sleep and circadian rhythm problems in ASD.

4:20 **196.003** Clinical and Circadian Aspects of Poor Sleep Quality

***A. L. Richdale**, Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

This presentation will briefly cover basic information about sleep structure, sleep as a circadian rhythm, and the impact of poor sleep quality as a background to discussion of the clinical and circadian aspects of sleep difficulties in autism spectrum disorder and their impact across the lifespan. Sleep has a circadian structure, with 24-hour cycles of waking and sleeping governed by the suprachiasmatic nucleus, and the neurohormone melatonin. The primary zeitgeber for the sleep-wake cycle is the light-dark cycle.Likewise the sleep EEG structure and pattern changes through infancy and early childhood, resulting in approximately 90-minute cycles of rapid eye movement sleep (REM) and non-REM sleep in children and adults. Poor sleep quality can negatively impact learning and memory, mood and behaviour, and physical health. While there is a vast array of sleep problems, the most common are those associated with sleep onset and maintenance, and insufficient sleep. Sleep disorders most commonly associated with these symptoms include behavioural sleep disorders in childhood, insomnia, and circadian sleep-wake rhythm disorders (CSWRDs). Poor sleep in autism begins in early childhood, when sleep patterns begin to deviate from those of age-matched peers, continuing into at least middle age. Across this age range some 50-80% of autistic individuals will suffer from significant symptoms of insomnia or CSWRDs, and at least in childhood, these sleep problems are often chronic. Sleep problems in children with autism spectrum disorder can also have a significant behavioural component. In autism associations between poor sleep quality and intensified autistic symptomatology, aggression, peer relationships, psychopathology, unemployment, screen time, gastrointestinal symptoms, melatonin and clock genes are reported. Parents' sleep and wellbeing is also affected. Nevertheless, the aetiology of increased susceptibility to poor sleep quality in autistic individuals remains unknown. There are likely subgroups and multiple causal factors including hyperarousal and differences in the melatonin rhythm. Research that examines aetiology, impacts on the individual with autism, and intervention is required.

4:45 **196.004** Approaches to Improving Sleep in Autism across the Lifespan

***B. A. Malow**, Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN*

Sleep problems are common in children with autism spectrum disorder and persist into adolescence and adulthood. Improving sleep can impact favorably on an individual's overall health, as well as daytime behavior and quality of life. Family quality of life may also improve when a child's sleep is improved. This presentation will discuss behavioral and pharmacological approaches to treating sleep problems in autism across the lifespan, with an emphasis on insomnia (defined as difficulty initiating or maintaining sleep).
For insomnia, supplemental melatonin is the most studied agent, and is effective in many individuals with autism with minimal adverse effects. Novel preparations of prolonged-release melatonin, which also improve night wakings, and melatonin agonists are becoming more available. However, the mechanisms whereby melatonin and melatonin agonists promote sleep are not clear, and in many individuals, insomnia may persist after treatment with melatonin. A wide variety of other medications are used to treat insomnia in autism, many with minimal evidence and significant potential for adverse effects. Behavioral sleep education and other non-pharmacological approaches have shown promise, although additional study is needed for how to effectively deliver these interventions, combine them with medications, and tailor treatments to individuals across the autism spectrum. The use of practice pathways to guide treatment, along with questionnaires and actigraphy to monitor treatment, will also be addressed.

Panel Session
Neuroimaging
197 - Advances in Mechanisms of ASD Connectopathy: Multiscale Perspectives
3:30 PM - 5:30 PM - Room: 517A

Panel Chair: Adriana Di Martino, *The Child Mind Institute, New York, NY*

The last decade has witnessed a burgeoning of neuroimaging studies substantiating models of atypical brain connectivity in Autism Spectrum Disorder (ASD) – connectopathy. Yet, their promise to lead to clinically useful ASD biomarkers remains unmet. A key challenge has been the variation of neuroimaging findings across studies. In fact, mixed reports of hypo- and/or hyper-connectivity affecting a range of neural circuits have left the precise nature of ASD connectopathy unclear. Additionally, a primary investigative focus on phenomenology has limited the progress on capturing underlying mechanisms. Here, we will introduce state-of the-art multidisciplinary work aimed to address these gaps. To this end, empirical findings from studies on idiopathic and/or genetically determined ASD, using multiscale time and space investigations will be presented. These will be integrated with studies targeting heterogeneity as a source rather than a confound and emphasizing replicability and reproducibility. In doing so, this panel will provide an advanced framework highlighting the next steps necessary for delineating clinically useful biomarkers and discerning the mechanisms at the origin of brain connectopathy in ASD.

3:30 **197.001** A Study of Cortical Functional Network Hierarchy: A Novel Perspective on Atypical Connectivity of Autism

***B. Bernhardt**, Neurology and Neurosurgery, Montreal Neurological Institute, Montreal, QC, Canada*

Background:
Together with its parallel and modular architecture, network hierarchy has been widely recognized as key principle of human brain organization. This overarching system is thought to facilitate abstract, high-order cognitive functions by helping segregate information that reflects sensory and motor interactions with the immediate environment from more self-generated operations emerging in transmodal, integrative cortices. As ASD is linked to deficits both in sensory processing and high-level cognitive functions such as theory of mind, analysis of macroscale brain network hierarchy may provide a parsimonious account to consolidate its diverse symptoms.

Objectives:

I will present novel findings from resting-state functional MRI (rs-fMRI) connectome analysis, harnessing recent analytical approaches to characterize hierarchical segregation between higher order transmodal areas and lower order systems in a multi-site cohort of individuals with autism and typically-developing controls

Methods:

We studied 103 males with ASD and 108 neurotypical males from three sites of the ABIDE dataset. Rs-fMRI time series were mapped to cortical surfaces in subject-specific space, followed by time-series cross-correlation of all surface-points. Nonlinear connectome compression techniques identified principal gradients of spatial variations in connectivity across the cortical mantle in individual subjects. Following Procrustes alignment, we used surface-based linear models to compare gradient scores in ASD to controls, controlling for site, age, and multiple comparisons. We furthermore carried out a systematic step-wise functional connectivity (SFC) analyses initiated in primary sensory seeds (primary visual, auditory, somatosensory cortex). Supervised pattern learning leveraged hierarchy features to predict symptom severity as indexed by the Autism Diagnostic Observation Schedule (ADOS) within a 5-fold cross-validation setting.

Results:

Compared to typically-developing controls, ASD showed contracted rs-fMRI connectome gradients, indicative of atypical hierarchical segregation, between higher-order transmodal areas and lower order systems. While SFC patterns in controls recapitulated gradient-based findings, showing a selective convergence of sensory-initiated connectivity in default mode core hubs**,** ASD presented with distorted patterns and a failure to converge in the default mode network. Effects were reproducible across included sites, in an independent validation dataset (n=110; 53 ASD, 57 neurotypical individuals), and with respect to several rs-fMRI processing choices. Using supervised pattern learning, we could furthermore show that imaging features capturing hierarchical network imbalances predict symptom severity in individuals with ASD, supporting the behavioral relevance of our findings.

Conclusions:

Our study shows that ASD is characterized by perturbations in macroscale cortical hierarchy, which may consolidate its seemingly paradoxical combination of low-level and higher-order symptoms.

3:55 **197.002** Using MEG to Measure Rhythm Specific Functional Connectivity in ASD

***T. Kenet**, Massachusetts General Hospital, Charlestown, MA*

Background:
Since about 2004, findings of functional connectivity (FC) abnormalities have motivated an important line of research on the neurophysiological etiology of autism spectrum disorder (ASD). These findings led to the framing of ASD as a disorder of brain connectivity, with the most common hypothesis being that long-range FC is abnormally reduced in the brain in ASD, and local FC is abnormally increased. While appealing in its simplicity, this idea has been repeatedly challenged over the past few years by inconsistent and conflicting findings. In parallel, the importance of the cortical rhythms has become central in the study of both normal and abnormal brain function. However, despite many studies in Autism Spectrum Disorders (ASD), there remains a gap in our understanding of how the 5 intrinsic neuronal rhythms delta, theta, alpha, beta and gamma contribute to cortical function abnormalities in ASD in general, and across different spatial scales of functional connectivity more specifically.

Objectives:

To test rhythm specific functional connectivity abnormalities in ASD, both locally, and across distant cortical regions (long-range), from childhood through adolescence.

Methods:

We used source localized magnetoencephalography, which has millisecond temporal resolution and good spatial resolution, to probe frequency-band specific functional connectivity differences in ASD across a range of paradigms, spatial scales, and measures. We examined the results in a wide age range (7-18); sample sizes varied by paradigm, and ranged from about 15 to 40 per group.

Results:

Results from multiple paradigms converged towards normal or reduced local functional connectivity in ASD, alongside increased functional connectivity in the bottom-up direction and reduced functional connectivity in the top-down direction. More specifically, results from a

somatosensory based paradigm indicated increased long-range functional connectivity in ASD in the bottom-up direction alongside reduced local functional connectivity. Results from visual somatosensory paradigms indicated reduced local and top-down long-range functional connectivity. Results from resting state were consistent with reduced long-range functional connectivity in the top-down direction, manifesting in the beta (13-30Hz) frequency band, and increased long-range functional connectivity in the bottom-up direction, manifesting in the gamma (30-80Hz) frequency band. In parallel, we also found that the results were dependent on the age of the participants, which shifts occurring over adolescence.

Conclusions:

The pattern of functional connectivity abnormalities in ASD is extremely complex, and cannot be reduced to general hypotheses. Spatial scale (local versus long-range) is a critical variable when considering these abnormalities, but even when narrowing down spatial scale, factors such as the specific frequency band, age of the participants, directionality, and the paradigms used, need to be considered carefully.

4:20 **197.003** Are There Reproducible and Replicable Connectivity Patterns in the Intrinsic ASD Connectome?

***A. Di Martino**, The Child Mind Institute, New York, NY*

Background:

Heterogenous reports of hypo- and/or hyper-connectivity affecting different neural circuits have cast doubts on the validity and utility of connectivity models of ASD. Recently the field has begun to amass the samples and approaches necessary to test robustness and reproducibility of findings. This is a critical step towards the testing and refinement of connectivity models.

Objectives:

To examine, using multiple and relatively large samples, the extent to which patterns of mixed hypo- and hyper- connectivity in ASD are consistent, are represented by distinct connectivity subtypes, and associated to specific functional neuronal systems, clinical impairments and biological sex.

Methods:

Three resting state fMRI (R-fMRI) studies of large-datasets examining the whole brain architecture will be presented. *Study 1* examined functional connectivity cortical and subcortical units in an independent male-only sample selected from ABIDE II using the same criteria as the original ABIDE I report (N=298 ASD and N=339 typically developing controls [TC]). *Study 2* (collaboration with T Yeo's laboratory at U Singapore) applied a Bayesian model inge identification of latent distinct, but possibly overlapping, connectivity factors in a sample of both males and females (F) selected from ABIDE II and GENDAAR (N=306 ASD, N=348 TC). Associations with clinical measures were analyzed using canonical correlations. *Study 3* examined the reproducibility of diagnosis, sex and sex by diagnostic interaction effects across multiple R-fMRI metrics in the same dataset (ABIDE I and II: N= 444 [82 F] ASD, N=576 TC [166 F]) analyzed with different pipelines and across independent samples after removing batch effects (GENDAAR: N=87 ASD [44 F], N=89 TC [53 F]; EUAIMS: N=173 ASD [43 F]; N=153 TC [48 F]). Analyses were conducted controlling for micromotion at the individual and group levels and using stringent statistical correction.

Results:

Study 1: consistent with prior results in ABIDE I sample, analyses revealed whole-brain pattern of coexisting hypo and hyper-connectivity in ASD relative to TC. Hypo-connectivity characterized cortico-cortical regions albeit with a lesser extent than previous findings. Hyperconnectivity affected subcortico-cortical circuits with primary somatomotor and unimodal association units being mostly affected. *Study 2*: Bayesian analyses revealed three dissociable whole-brain connectivity factors, each with coexisting ASD-related hypo and hyper connectivity. Importantly, most ASD participants expressed multiple factors with different degree of probability; each factor each was differently associated to core ASD, comorbid symptoms or sex. *Study 3:* While statistically significant effects of diagnosis, sex and their interactions identified in the ABIDE II dataset were largely robust to the preprocessing pipeline, their replicability across samples varied with by R-fMRI metrics and particularly for diagnostic effects.

Conclusions:

Mosaic patterns of co-existing hypo- and hyper- connectivity characterize ASD. Their variation in the specific network and metrics affected underscore the relevance of emerging data driven approaches accounting for heterogeneity. Findings that differential combination of brain functional connectivity represent each individual are consistent with models of continuous ASD heterogeneity. Challenges in identifying reproducible sex differences in the neural basis of ASD likely reflect the relatively limited availability of data in affected females and identifies a gap needing greater attention.

4:45 **197.004** Mapping the Neuro-Connectional Landscape in Autism with Cross-Species fMRI

***A. Gozzi**, Istituto Italiano di Tecnologia, Functional Neuroimaging Lab, Centre for Neuroscience and Cognitive Systems, Rovereto, Italy*

Background:

Functional brain mapping using resting-state functional magnetic resonance imaging (rsfMRI) and other imaging techniques has revealed prominent, yet highly heterogeneous abnormalities in interregional connectivity in individuals with autism. However, several fundamental questions as to the origin and significance of this phenomenon remain unaddressed.

Objectives:

This research tackles two major open questions in the field: (a) does genetic or etiological variability associated with autism account for the heterogeneous rsfMRI findings observed network disruption? (b) Can we link individual autism-associated genetic etiologies or pathophysiological motifs to specific patterns of rsfMRI dysconnectivity?

Methods:

We have developed rsfMRI-based methods for connectivity mapping in the laboratory mouse, where genetic determinants and neuronal activity can be controlled with high precision. To probe the translational relevance of our measurements, we have mapped and compared rsfMRI connectivity patterns in human carrier of 16p11.2 deletion (*del*; SFARI VIP cohort), and a mouse line harboring an orthologous chromosomal

deletion. We have next applied our rsfMRI approach to map N = 20 different mouse lines (collaboration with ETH, Zurich) harboring high-penetrance mutations associated to syndromic forms of autism, with the aim to identify etiologically-relevant connectional fingerprints representative of human ASD heterogeneity.

Results:

We observed remarkable correspondences between mouse and human fMRI network organization, enabling a direct extrapolation of imaging features across species. Corroborating the translational relevance of our approach, rsfMRI mapping in human 16p11.2 *del* patients and a mouse model recapitulating the same genetic defect, revealed highly consistent prefrontal hypoconnectivity. We next applied this approach to multiple mouse lines harboring autism-associated mutations. Results showed that different genetic etiologies can give rise to diverse even diverging, yet classifiable cross-mutational connectivity fingerprints, and that these alterations are associated with disrupted fMRI network dynamics.

Conclusions:

Our results establish a mechanistic link between specific neuro-genetic etiologies and distinct patterns of dysconnectivity and point at a key contribution of etiological variability to the observation of heterogeneous patterns of connectivity in ASD. The implication of these findings for the origin and mechanistic interpretation of rsfMRI findings in human ASD studies will be critically discussed.

Oral Session -
Invited, Keynote Speakers, Awards
199 - Keynote Address - Vikram Patel, MBBS, PhD
5:30 PM - 6:30 PM - Room: 517A

5:30 From Clinics to Communities: Addressing Global Disparities in Autism Care

***V. Patel**, Harvard Medical School, Boston, MA*

The vast majority of the world's children with autism live in low and middle income countries; in contrast, the vast majority of the resources to support families and children impacted by autism are concentrated in high income countries. As a result, the detection and diagnosis of autism in low income settings is delayed by several years; and for those families and children who are able to get a diagnosis, only a tiny proportion will receive any clinical intervention. Those that do will often be relying entirely on poorly evidenced specialized care of uncertain quality at high out-of-pocket cost. This lecture will describe the innovative approaches of a program of research in South Asia which has sought to address these large detection and care gaps. The approach has adapted well-evidenced practice in UK into low resource settings using community delivered technology and front-line worker enabled interventions, and has done this without loss of original intervention quality or effectiveness. The focus will be to consider how such approaches may help expand access to evidence based care for the large majority of the world's children who are currently unreached.

Poster Session
200 - Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational
5:30 PM - 7:00 PM - Room: 710

1 **200.001** Educational Outcomes from a Longitudinal Study of the SSC Cohort

***B. Vernoia**[1], E. Brooks[1], C. W. Lehman[1], L. A. Green Snyder[1], K. Walton-Bowen[2] and W. K. Chung[3], (1)Simons Foundation, New York, NY, (2)Clinical Research Associates, LLC, New York, NY, (3)Pediatrics, Columbia University, New York, NY*

Background: The Simons Simplex Collection (SSC) contains 2,644 families, each with only one family member with an Autism Spectrum Disorder (ASD). Approximately 1,500 participants joined the online research registry SSC@IAN (Interactive Autism Network) and were invited to complete an online longitudinal follow-up study questionnaire. This study examines predictors of educational outcomes in dependent and independent adults with ASD.

Objectives: To describe educational outcomes in adults with ASD in SSC.

Methods: Full scale IQ (FSIQ), Autism Diagnostic Observation Schedule (ADOS) and Vineland Adaptive Behavior Scales-2ndeditionwere collected at baseline in 8 to 17-year olds in the SSC, and education history and other updates were completed at follow-up an average of 8 years later. Regression analysis was conducted for predictors of current and completed level of education, specifically college attendance.

Results: Of 84 dependent and 23 independent adults completing the follow-up survey, 80% were male, and the majority of the sample was of European ancestry (88%). The mean age at follow-up was 21 years (range 18 to 26). 78% of adults declared independent had average-or-above IQ in childhood vs. 20% of those declared dependent. Together, at baseline, FSIQ distribution showed: 41% <70 (impaired), 14% 70-79 (borderline-impaired), 12% 80-89 (low average), 17.7% 90-109 (average), 5.6% between 110-119 (high average), 9.3% >120 (superior and very superior range). 67.2% had fluent speech (Module 3/4), but mean Vineland expressive language age equivalent (AE) was 5.2 years. Mean ADOS Calibrated Severity score (CSS) was 7.6.

Level of completed education at follow-up was categorized as: alternate special education diploma (39.6%), high school diploma or GED (37.5%), some college coursework (6.2%), bachelor's degree (10.4%), and other/ "not sure" (6.3%). In terms of those currently attending school (55%), 49% are attending high school, 11%, vocational/trade school, and 40%, college.

Of those who completed a bachelor's degree or some college, including those currently attending college, 70% had average-to-above average IQ at baseline, while 30% had below average to impaired IQ. 97% had fluent speech by school age (ADOS Module 3). Mean expressive language AE was 7 years (range 2-10.5) at baseline. 73.3% had a moderate to severe CSS (6-10).

In multiple regression analysis, FSIQ score significantly predicted college attendance (p<.0005), while severity (CSS) and language level (ADOS module or Vineland expressive AE) were not significant.

Conclusions: Outcome in adulthood is a common concern of parents of children with ASD. The SSC@IAN cohort provides the opportunity to investigate longitudinal outcomes. Of the now-adult SSC participants who completed the follow-up study, over 25% later attended college, including those who are not legally independent in adulthood. Individuals who go on to attend college show a surprisingly wide range of IQ and symptom severity; however, similar to other outcome research in ASD, IQ is the best predictor of later attainment. Identification of reliable predictors can helpfamilies to prepare for the future.

2 **200.002** Educational and Vocational Disengagement of Young Adults with a Special Education Need and Autism in the United Kingdom

M. Kovacs[1], *S. Griffiths*[1], *C. Allison*[2] *and S. Baron-Cohen*[2], *(1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Successful transition to adulthood poses a great obstacle for many young people with special education needs (SEN) and autism. Compared with the general population, autistic people are over twice as likely to be 'not in employment, education or training' (NEET). Being NEET has wide-ranging implications from poor mental health and suicidal ideation to economic viability and independence. It is known that SEN status and autism are themselves risk factors for disengagement. However, little is known about what social and educational vulnerabilities are linked to NEET outcome in the SEN and autistic population.

Objectives: Using data compiled by the UK government, the current study aims to explore how autism and other special education needs are linked to educational and occupational disengagement, taking into account additional factors relating to educational and social vulnerabilities.

Methods: All data originated from the National Pupil Database, obtained by permission of the Department for Education. The database contains information about school-aged children in state-funded schools across the UK. For this analysis, the National Client Caseload Information from 2016 (N= 2,289,792) was used to identify pupils who have become NEET. Using unique pupil identification numbers, we linked this data to the School Census for the preceding academic year 2014-2015 (N= 7,845,011) to obtain information on demographic variables (age, gender, first language, ethnicity) as well as the official SEN status of students (Autism, Other SEN category, No SEN). To account for further social and educational vulnerabilities we also linked social service records and records on school absences and exclusions. Logistic regression was used with NEET as the binary outcome to determine the odds of disengagement depending on SEN category (Autism, Other SEN category, No SEN).

Results: After controlling for demographic variables and social-educational vulnerabilities, autistic young people were significantly more likely to be NEET compared to young adults with no SEN (odds ratio = 1.23, 95% CI 1.04-1.44). Young people with other SENs were also significantly more likely to be NEET compared to young people with no SEN (odds ratio =1.87, 95% CI 1.79-1.96). Statistical comparison of coefficients revealed that the effect of having a SEN other than autism was significantly greater than the effect of having a diagnosis of autism alone in terms of becoming NEET ($\chi^2 = 25.04$, $p<0.000$).

Conclusions: After adjusting for the effect of demographic variables and social-educational vulnerabilities, we found that a diagnosis of either autism or another SEN significantly increases the odds of becoming NEET, indicating that SEN status independently increases the likelihood of educational and vocational disengagement in the UK. We also found that having autism is less strongly associated with NEET outcome compared to having a different SEN. A limitation of this study is that it only includes pupils from state-funded schools, therefore it does not account for certain segments of the population. Future work will examine how each major SEN sub-type is linked to NEET outcome and how social-educational vulnerabilities mediate disengagement across these groups.

3 **200.003** Employers' Perspectives on Individuals with IDD Working in Integrated Employment Settings: A Systematic Literature Review

L. S. Athamanah[1,2], *K. White*[3], *C. Sung*[4], *G. Leader*[5] *and M. H. Fisher*[1], *(1)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (2)Psychology, National University of Ireland, Galway, Galway, Ireland, (3)National University of Ireland, Galway, Galway, Ireland, (4)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI, (5)National University of Ireland, Galway, Ireland*

Background: Individuals with intellectual and developmental disabilities (IDD), which include autism spectrum disorder (ASD) and intellectual disability (ID), experience high rates of unemployment and underemployment. In 2016, 68.6% of adults without disabilities were competitively employed, relative to 26.3% of individuals with ID (Kraus et al., 2018) and 14% of individuals with ASD (Roux et al., 2017). To improve sustainable employment outcomes, it is imperative to take an ecological systems approach by examining factors and perspectives from both demand-side (employer) and supply-side (employee) that may impact employment opportunities. Studies show that negative societal attitudes toward hiring and/or working with people with IDD contribute to poor employment outcomes (Smart, 2008). Addressing these negative attitudes will create a more inclusive employment culture and diminish the prejudice and discrimination that has become a barrier for individuals with IDD to obtain and maintain employment in integrated work settings (Erickson et al., 2014). Therefore, understanding employers' perspectives on individuals with IDD working in integrated employment settings is necessary to potentially improve their employment outcomes.

Objectives: The purpose of this systematic literature review is to summarize the research conducted on the perceptions and attitudes of employers on individuals with IDD working in integrated employment settings.

Methods: An extensive literature search on articles published before 2018 that focused on employers' perspectives of individuals with IDD working in integrated employment settings were conducted. After the initial search was completed, titles and abstracts of the 1765 articles were screened. Inclusion criteria included: (a) contains information on employer perspectives, attitudes, or beliefs about individuals with IDD in the workplace; (b) study is either quantitative or qualitative in nature; (c) include employers in the participant pool; (d) data collected via surveys/questionnaires /interviews); and (e) was published in English. Sixty-nine articles were subsequently identified and thoroughly examined to confirmed the suitability of the articles. This resulted in 33 articles to be included in the final review. Following this examination, ancestral (i.e., reference list review) and forward searches (i.e., Google citations) were conducted with 30 additional articles identified for a total of 63 articles included in the final review.

Results: Based on the 63 articles identified, preliminary data show that <50% employers have prior experience working/hiring individuals with IDD and most employees in these workplaces have an ID versus ASD. Findings also demonstrate that studies have been conducted globally using

primarily a quantitative/descriptive methodology and informal non-validated survey tools. Included studies' outcomes have demonstrated that when employers had experience hiring/working with an employee with IDD, they were satisfied with the employee's performance and would continue to hire people with IDD if adequate support was provided.

Conclusions: There are few studies and minimal evidence available to inform employment interventions for individuals with IDD from the employers' perspective or which supports the employer requires. Individual studies suggest a positive shift in knowledge and attitudes towards individuals with IDD at work, however, our understanding on how to promote the hiring of and maintaining individuals with IDD in the workplace is limited.

4 **200.004** Executive Functioning in Middle Adulthood: A Follow up Study of Children Diagnosed with ASD from 1970-1999

J. L. Mussey[1], *M. R. Klinger*[2], *A. T. Meyer*[3], *K. M. Dudley*[4], *R. K. Sandercock*[4] *and L. G. Klinger*[5], *(1)TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (4)UNC TEACCH Autism Program, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: Executive functioning (EF) refers to a range of higher order cognitive skills, which are considered integral to goal-directed, flexible behavior. Impairments in EF are reported in ASD, though there is some disagreement about the pattern of impairments. While there are a growing number of adults with ASD, less research is available on EF in middle adulthood and ASD and its relations to other aspects of adult functioning.
Objectives: Objectives of this study were to: 1) examine the profile of EF strengths and weaknesses in adults with ASD; 2) compare ratings of real-world EF skills to standardized, behavioral measures of EF; 3) examine how executive functions relate to other measures of functioning (adaptive behavior, employment, quality of life) in middle adulthood for individuals with ASD diagnosed as children.

Methods: Participants were 24 adults with ASD (age range 27-57 years; M age=35) who completed behavioral assessments of EF (D-KEFS: Trail Making Test, Color-Word Interference, Verbal Fluency), self-reported EF (BRIEF-Adult Version), and IQ (Stanford Binet-5; FSIQ range 73-120; M FSIQ=91.3). Caregivers of adults with ASD completed measures assessing their adult's EF (BRIEF-Adult Version), a measure of adaptive behavior (Vineland-II), and questions about the adult's employment and quality of life. Analyses were conducted to examine the profile of EF in middle adulthood and the relation of EF to areas of adult functioning.

Results: 1) Across domains assessed, adults with ASD performed similarly on D-KEFS subtests (scaled score range 7.0-9.21, *p*'s > .05) to the expected performance for adults with similar FSIQ (z-score transformed mean = 8.27). However, they reported significantly more difficulties on self- and informant-report BRIEF-A indices (t-score range 54.25-57.21 compared z-score transformed mean). 2) Controlling for FSIQ, the only D-KEFS measure correlated with self- or informant-report on the BRIEF-A was Color-Word Interference Inhibition (both *r*'s > -.51, *p*'s < .02), such that difficulty with D-KEFS inhibition was associated with EF difficulties on the BRIEF-A self- and informant-report. 3) Controlling for FSIQ, D-KEFS Color-Word Inhibition switching and Verbal Fluency switching were positively correlated with the Adaptive Behavior Composite on the Vineland-II (both *r*'s > .44, *p*'s < .05). D-KEFS and BRIEF-A performance were not related to employment length, hours worked per week, or wages. D-KEFS was not related to overall quality of life (all *r*'s < .02, *p*'s > .05). BRIEF-A informant-report was significantly negatively correlated with informant-reported overall quality of life (*r* = -.55, *p*'s < .008), such that EF difficulties were related to lower quality of life.

Conclusions: Overall, adults with ASD performed similarly on the D-KEFS to adults at similar levels of cognitive ability. However, on ratings of everyday executive function, adults performed more poorly than predicted by intellectual ability. Overall, behavioral measures of EF and ratings of everyday EF were minimally correlated with each other suggesting that they are measuring different constructs. Both reports of everyday EF and standardized measures of EF contributed to our understanding of adult adaptive behavior and quality of life outcomes suggesting that both types of measures may be important to administer.

5 **200.005** Exploring Barriers to Employment for Individuals on the Autism Spectrum: Perceptions of Autistic and Non-Autistic Job Candidates at Interview

R. L. Flower[1], *D. Hedley*[1] *and L. M. Dickens*[2], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)La Trobe University, Melbourne, Australia*

Background: Adults with a diagnosis of autism spectrum disorder (hereafter autistic) face considerably lower employment rates compared to the general population. In Australia, only 40.8% of working aged autistic individuals are employed, compared to 53.4% of individuals with a disability and 83.2% of individuals without a disability (Australian Bureau of Statistics, 2015). One suggested barrier is the job interview due to its heavy reliance on social skills, which are, by definition, different among autistic individuals (American Psychiatric Association, 2013).
Objectives: The current study investigated perceptions of autistic and non-autistic job candidates using 10 second videos of simulated employment interviews. The aim was to understand how disclosure of autism during the job interview may affect perceptions of employability and hiring outcomes for autistic adults.

Methods: 353 individuals (40.2% male, 59.2% female, 0.6% unspecified, age *M* = 35.27 years, *SD* =12.71 years) were recruited via online platform Prolific Academic. Disclosure of ASD was manipulated using videos, with three levels of information: no autism disclosure, brief autism disclosure, and detailed autism disclosure, which corresponded to the three experimental conditions. Participants were randomly assigned to one of the three conditions and were each shown two 10 second videos of a 'job candidate' (one autistic candidate, one non-autistic candidate), presented in random order. They were then asked to make a judgement on their each candidates' employability and make a decision regarding which of the two candidates they would 'hire'.

Results: Across conditions, participants chose to 'hire' the autistic job candidates in 37.5% of the time, and non-autistic job candidates 66.3% of the time. A mixed 2 (diagnosis) X 3 (condition) ANOVA investigating ratings of candidate employability revealed a significant effect of diagnosis, $F(1,350) = 53.65$, $p < .001$, whereby autistic individuals were rated lower on employability, a significant effect of condition, $F(1,350) = 4.17$, $p = .016$, whereby employability ratings of autistic individuals improved between disclosure conditions, and a significant interaction between diagnosis and condition, $F(2,350) = 4.04$, $p = .018$, whereby employability rating for autistic candidates changed between conditions while the rating of non-autistic individuals remained relatively stable. The presentation will explore post-hoc comparisons of results, explore whether data patterns were different depending on relationship with autism (e.g., if autistic, or a family member of an autistic individual), and other measures on which

candidates were assessed.

Conclusions: The results showed that the autistic job-candidates were less likely to be 'hired' compared to their non-autistic counterparts and were rated significantly lower on employability. Further, employability rating changed between conditions, showing an influence of autism disclosure. These results, and what this indicates about the job interview as a barrier for autistic individuals, will be discussed.

6 **200.006** Job Seeking Experiences of Autistic and Non-Autistic Youth

R. L. Flower[1,2], *A. L. Richdale*[1] *and S. Arnold*[3], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)The University of New South Wales, UNSW Sydney, Australia*

Background: Engaging in employment can result in a number of positive outcomes for autistic individuals (e.g., Hedley et al., 2017; Lounds Taylor, Smith, & Mailick, 2014). However autistic individuals often face significant challenges in seeking, gaining and maintaining employment (Baldwin, Costley, and Warren 2014; Lopez and Keenan 2014; Hedley et al. 2017, 2018; Harmuth et al. 2018; Wei et al. 2018). In Australia, this is reflected in the labor participation rate of 40.8% among autistic individuals, which is lower than individuals with and without a disability (53.4% and 83,2% respectively; Australian Bureau of Statistics [ABS], 2015). Among transition aged youth on the autism spectrum, successfully gaining employment has been cited as a common challenge (e.g., Roux et al., 2013; Shattuck et al., 2012), and vocational outcomes among this group have been cited as low (e.g., Pounds Taylor & Seltzer, 2011).

Objectives: The current study explored the job seeking experiences of transition aged autistic and non-autistic youth aged 15-25 years who were recruited as a part of a larger longitudinal study.

Methods: Data were extracted from the first phase of a national longitudinal online study of autistic and non-autistic youth aged between 15-25 years (M = 19.39, SD = 2.33). Respondents were N = 252 individuals, of whom n = 136 identified as autistic and n = 116 identified as non-autistic (46 % male, 54% female) who answered a series of questions about their job-seeking experiences adapted from the Labour Force Survey (ABS, 1960).

Results: Of the 252 individuals, 39% (n = 53) of the autistic individuals reported seeking work, while 43.1% (n = 50) of the non-autistic respondents reported actively seeking work.

There were no differences in the number of jobs applied for over a three month period between the autistic (M = 11.48, SD = 18.79) and non-autistic (M = 15.21, SD = 16.70) individuals, $t(93) = 1.023$, $p = .309$. However, the autistic respondents (n = 48) reported applying up to 103 jobs, while the non-autistic respondents (n = 47) reported applying for up to 60 jobs.

Autistic job-seekers reported using less strategies in their search for a job (M = 1.87, SD = 1.74) than non-autistic job seekers (M = 2.52, SD = 1.47), $t(101) = 2.044$, $p = .044$.

Autistic and non-autistic job seekers reported similar levels of success in their search for a job, with 17% (n = 9) of autistic, and 18% (n = 9) non-autistic individuals reporting finding a job.

Conclusions: While autistic individuals reported less strategies in their search for employment, a similar number of autistic and non-autistic respondents reported seeking employment, and a similar number reported success in their search. These results are at odds with the existing literature addressing autism and employment.

This presentation will further explore the data, to look at whether their role involves additional support, the number of hours each group reported working, and the perceived reasons for not finding work for those who were unsuccessful across the two groups.

7 **200.007** Feasibility of Schema Therapy in Young Adults with High-Functioning Autism Spectrum Disorder in Japan: A Pilot Study

F. Oshima[1], *T. Murata*[2], *T. Ohtani*[3], *I. Shaw*[4], *M. Seto*[1], *A. Nakagawa*[1] *and E. Shimizu*[1], *(1)Research Center for Child Mental Development Chiba University, Chiba, Japan, (2)chiba university, Chiba, Japan, (3)Chiba University, Chiba, Japan, (4)Schema Therapy Institute Midwest, Indianapolis, IN*

Background:

Individuals with autism spectrum disorder (ASD) have better subjective prognosis or higher quality of life (QOL) when they are diagnosed in childhood (Kamio, 2012). However, diagnosis is often delayed until adulthood in high-functioning ASD (HF-ASD) individuals, who may not receive the appropriate care or support (Mandy et al., 2012). Furthermore, undiagnosed ASD individuals are at a higher risk for mistreatment, such as bullying or abuse (White, 2009); 65%–80% of ASD adults have accompanying mental disorders, including depression and anxiety. Schema therapy (ST) is a psychotherapy that has evolved from cognitive behavior therapy with good therapeutic results on complicated diseases, such as personality disorders and post-traumatic stress disorder (Hawk & Provencher, 2012). Additionally, it has shown positive results for borderline personality disorders. However, there are few studies of ST in HF-ASD adults (Vuijk & Arntz, 2017). ST follows the process of understanding nonfunctional coping mechanisms that an ASD individual has been implementing for many years, while instilling and implementing new coping mechanisms. We believe that ST is effective in HF-ASD individuals suffering from a sense of chronic social maladaptation; therefore, we examined the effectiveness of ST in a pilot study.

Objectives:

This study evaluated the feasibility, acceptability, and preliminary effectiveness of ST in 10 HF-ASD individuals with comorbidity of psychiatric disorders.

Methods:

Ten HF-ASD individuals (age, >20 years) with at least one psychiatric symptom were administered a treatment protocol comprising 30 weekly offered sessions. A concurrent multiple baseline design was used, with a baseline of 1–3 weeks, followed by a psychological assessment using developmental tests such as autism diagnostic interview-revised and autism diagnostic observation schedule. Next, the study therapist started a psychological education with the patients about HF-ASD and ST for 5–8 weeks, which was followed by a 10-week exploration phase with weekly sessions wherein current and past functioning, psychological symptoms, and schema modes were explored and information about the treatment was provided. Subsequently, 15 weekly sessions in cognitive-behavioral interventions and 20 weekly sessions in experiential interventions were conducted. Finally, a follow-up session was conducted 3 months after the intervention. During pretreatment, posttreatment, and follow-up session, we evaluated the Global Assessment of Functioning score as the main outcome from independent researchers in this study as well as WHO-QOL scale and other psychiatric symptom severity scales .

Results:

Regarding pretreatment and posttreatment scores, we found significant reduction in symptoms of depression and improvement in social functions and QOL. Effect sizes of Cohen's d was 3.3 for global assessment of functioning, 0.69 for WHO-QOL, 0.62 for maladaptive schema reduction increase, and 0.56 for mode reduction. Regarding follow-up score, we found significant reduction in symptoms of general anxiety, social anxiety, and obsession and significant in overall functioning (Fig.1).

Conclusions:

To our knowledge, this is the first uncontrolled clinical trial to provide evidence that ST combined with psychoeducation in ASD can be implemented and adapted for use in short-term outpatient settings. However, generalizability of this study is limited owing to the small sample size and lack of control group.

8 **200.008** GPS Mapping of Community Participation Patterns in Adults with Autism Spectrum Disorder

D. V. Chan[1], *L. G. Klinger*[2], *M. R. Klinger*[3] *and I. S. Robson*[4], *(1)Allied Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (3)UNC TEACCH Autism Program, Chapel Hill, NC, (4)Department of Statistics & Operations Research, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:

The presence of meaningful daytime activity is one of the most important factors contributing to quality of life for adults with ASD (Tobin et al., 2014). Yet little is known about how adults spend their time, whether they consider their daytime activities meaningful, and if they feel connected to the community.

Objectives:

This study used Global Positioning Systems (GPS) measures to better understand where and how adults with ASD spend their time, how they interact with their community, and whether they feel connected in the community.

Methods:

Participants carried GPS trackers to capture time away from home, distance traveled, and locations visited for seven days. Travel diaries completed by participants or caregivers provided context for GPS locations. Follow-up interviews asked participants which locations were most important, where they felt most productive, where they felt they belonged the most, and if they felt part of the community. Results were combined with caregiver-reported adult outcome survey data to explore the role of communication skills, living situation (independent, with family, group home), and employment status on community participation.

Results:

Table 1 contains demographic and community participation outcomes for 23 adults aged 21-50 years across the spectrum (47% had ID) who completed the study. GPS measures of average time away from home was just over 5 hours per day although 39% had at least one day during the week they did not leave home. Number of unique locations visited during the week ranged from 5 to 59 (average=18.6). The individual's space occupied in the community area ("activity space") averaged 87.57 sq. mi., with social/recreational locations contributing to the largest spatial presence in the community. Social/recreational locations were also most frequently (52%) identified as "most important" and where participants wished they spent more time. Most participants identified home as where they felt they belonged the most (65%) and vocational locations as where they felt most productive (65%).

Most participants (83%) reported feeling part of their community, primarily due to feeling known by others in the community. No significant differences in feeling part of the community or any of the GPS participation outcomes were present by employment status or conversation ability. Qualitatively, those who lived in group homes or had family exerting significant effort in planning activities visited multiple locations during the week, while adults who were driving independently but unemployed averaged less than two hours away from home per day. These patterns were present across different geographic regions.

Conclusions:

Most individuals in the current study were involved in several activities in locations throughout the community area and felt connected to their community through personal interactions. Individuals traveled great distances to participate in social/recreational activities and rated these locations with high importance. Those who were unemployed or had less conversation ability were still engaging in the community in ways that were meaningful to them. Findings suggest that adults with good conversation ability but were unemployed had limited participation and may need more support services. Increased social/recreational opportunities for adults in the community are needed overall.

9 **200.009** Group Rehabilitation Program for Undergraduate Students Improves Their Social Adaptation Ability and Prevents Their Dropouts.

Y. Makiyama[1], *M. Kawashima*[1], *A. Tagawa*[1], *M. Imai*[1], *T. Yamada*[1] *and N. Kato*[1,2], *(1)Institute of Neuropsychiatry, Seiwa Hospital, Tokyo, Japan, (2)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan*

Background: Group rehabilitation for undergraduate and grad students with autism spectrum disorder (ASD) has not been established in Japan while that for adults has already been approved as a health insurance treatment. A previous study has shown that substantial number of undergraduate students with ASD unfortunately dropped out of their school and consequently being socially isolated because they could not ask for any effective supports around them in Japan (Takei et al. 2014). This result raises the possibility that developing a group rehabilitation program specialized for undergraduates could prevent their maladjustment to school life. Thus, it is necessary to develop a group rehabilitation program for undergraduates and evaluate its outcomes.

Objectives: We aim to evaluate how effective our group rehabilitation program specialized for undergraduate students is, utilizing longitudinal data that measures the degree of social adaptation.

Methods: We recruited 45 undergraduates with ASD who participated in our group rehabilitation program specialized especially for undergraduate students from July 2015 to June 2018. Our monthly one-year rehabilitation program included communication skill training and psychological education partly specialized for undergraduates (e.g. a role-play session about how to ask for professors and make friends with classmates). Out

of 45 participants we analyzed the data of 30 participants (4 female; mean age=20.7, SD = 2.0) who attended more than half of our rehabilitation sessions because we aimed to strictly evaluate the effectiveness of our program throughout a series of sessions and indeed we could not follow up the data of remaining 15 students. We used social adaptation self-evaluation scale (SASS) as a primary end point.

Results: We compared the scores in modified version of SASS for students completed at pre-intervention with those at post-intervention. A t-test showed that the scores of SASS at post-intervention was significantly higher than those at pre-intervention (t = 2.68, p = 0.01), which means that participants improved social functioning after the rehabilitation program. In fact, their outcomes after intervention were as follows: 17 participants were in school, 4 participants obtained jobs, 3 participants participated in employee assistance program, and 6 participants participated in other rehabilitation programs in our hospital after graduation. It was notable that no participant dropped out of their school.

Conclusions: Our preliminary results indicate that our group rehabilitation program specialized for undergraduates could help participants to be well adapted to their school life and consequently not to drop out of their school and be socially isolated.

10 **200.010** Happiness and Wellbeing of Autistic Young Adults and Their Families: Evidence from a Population-Based Twin Sample

S. J. Capp[1], *E. Colvert*[2], *V. L. Milner*[1] *and F. Happé*[1], *(1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, KCL, London, United Kingdom of Great Britain and Northern Ireland*

Background:
There is evidence that suggests those diagnosed with ASD in childhood have poor outcomes in young adulthood. One area which has received little attention is the happiness and wellbeing of emerging adults with ASD as a subjective measure of adult outcome. Given previous research has identified many young adults with ASD continue to reside with, or receive support from, family, happiness and wellbeing among family may also be important to consider.

Objectives:

This study used data from a population-based twin sample covering the whole autism spectrum. Objectives were to examine parent and twin wellbeing and happiness in families with and without a young person with ASD.

Methods:

Parental and self-report data were collected for young adults with ASD, their non-affected co-twins and a non-ASD comparison group. Parent and self-reports were independent i.e. parent reports were not always accompanied by twin self-reports and vice versa. A wide range of issues were explored by participant questionnaires including mental health, wellbeing and young adult outcomes.

Twins and parents self-reported their own levels of happiness/wellbeing on the 4-item Subjective Happiness Scale (Lyubomirsky & Lepper, 1999), Life Satisfaction Scale (Diener et al., 1985), and Life Orientation Test (tapping optimism; Scheier, Carver & Bridges 1994). The twins self-reported self-esteem was also assessed (Rosenberg, 1965). Self-report data was available for 45 young adults with a research diagnosis of ASD (78% male; mean age 18 years 11 months), 24 non-ASD co-twins (33% male; mean age 18 years 11 months) and 50 comparison twins (68% male; mean age 18 years 8 months). A total of 77 parent self-reports were available, 43 from families where one or both twins met criteria for ASD and 28 from comparison families.

Results:

Parents with one or both twins on the autism spectrum had lower levels of subjective happiness (t= -2.32, 69, p<.05), life satisfaction (t= -4.21, 69, p<.001) and optimism (t= -3.08, 69, p<.01) than parents of comparison twins. From twin self-reports it was shown that there were significant differences between groups (ASD, co-twins and comparison) in levels of subjective happiness (F=6.43, 2, p<.01), life satisfaction (F=12.55, 2, p<.001), optimism (F= 4.48, 2, p<.05) and self-esteem (F=16.96, 2, p<.001). Average ratings of subjective happiness and optimism were significantly lower in the ASD group than the comparison group, with the co-twin group showing intermediate levels between the two. However, with regards to life satisfaction and self-esteem ASD and co-twins both reported significantly lower levels than the comparison group.

Conclusions:

ASD twins, their parents and co-twins were less happy, had lower life satisfaction and optimism, and ASD twins and co-twins had lower self-esteem, than the comparison group. This indicates that family wide wellbeing and happiness could be impacted when one or more family members have ASD. Even into young adulthood this suggests that services and support targeting the whole family unit of affected individuals may be necessary.

11 **200.011** Heart Rate Variability and Psychopathology Influences on Face Recognition in People with and without ASD

E. Laurent[1], *A. L. Richdale*[1], *M. Uljarevic*[2], *I. Newman*[1] *and D. Hedley*[1], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA*

Background:
A significant body of research has examined face recognition in individuals with ASD and while this research suggests that they often exhibit deficits, studies have demonstrated important variability. However, most previous studies have compared average performance between an ASD group and a control group, ignoring the important heterogeneity occurring within ASD. It is well known that there is a high prevalence of comorbid psychopathology in ASD, such as anxiety and depression, and that individuals with anxiety and depression also experience face processing dysregulation. Moreover, research suggests sympathetic over- arousal, parasympathetic underactivity, or atypical interaction of both systems in ASD and literature in the general population shows that greater arousal, shown by lower heart rate variability, affects cognitive skills such as facial emotion processing. We hypothesised that autistic trait severity, anxiety, depression and ANS arousal together may negatively impact face recognition performance in individuals with and without ASD.

Objectives:

(1) Evaluate if autistic, social anxiety, anxiety and depression traits are correlated with face-recognition performance; (2) Assess if HRV is linked to face recognition; and (3) Determine which factors emerge as significant predictors of face recognition performance.

Methods:

Participants were 30 adults (21 typically developing, 9 with ASD) aged 18 to 59 years (M = 31.93, SD = 12.5 years). Participants undertook a face recognition task and completed online questionnaires evaluating autistic traits (abridged Adult Autism Spectrum Quotient; AQ-short), anxiety and depression (Hospital Anxiety and Depression Scale; HADS) and social anxiety (Severity Measure for Social Anxiety Disorder; SMSAD). Heart rate variability (RMSSD) during baseline and while performing the task was collected and analysed. According to the literature age, non-verbal intelligence (WASI-II) and gender can impact on face recognition, thus these variables were controlled for when examining performance. We utilised 5000 bootstrapped samples for correlation and regression analyses examining the relationship between face recognition variables, diagnosis, psychopathology scales, autistic traits and HRV.

Results:

Face recognition accuracy (A prime) was negatively associated with SMSAD BCa 95% [-.79;-.07] and task_RMSSD r=-.455, BCa 95% [-.72;-.12]. Response bias was associated with task_RMSSD r=.411, BCa 95% [-.76;-.07]. Hit rate correlated with HADS_ Anxiety r=-.459, BCa 95% [-.75;-.09] and task_RMSSD r=-.509, BCa 95% [-.75;-.22]. Finally, false alarm rate was associated with diagnosis r=.445, BCa 95% [.08;.76]. Regression analyses showed that task-RMSSD emerged as unique significant predictor for A prime (β=-.39, BCa 95% [-.004;-.001]) and response bias (β=.41, BCa 95% [.001;.014]). However, for hit rate both HADS_Anxiety (β=-.38, BCa 95% [-.285;-.026]) and Task-RMSSD (β=-.49, BCa 95% [-.073;-.016]) emerged as unique predictors, while age was a unique predictor (β=.40, BCa 95% [.021; .253]) for false alarm rate.

Conclusions:

These results suggest that levels of social anxiety, general anxiety and HRV affect face recognition above ASD traits or diagnosis. These results also demonstrate that distinct psychopathology symptoms affect different face recognition variables and could explain the important heterogeneity within the ASD population. Findings emphasise the need to evaluate individual differences (psychopathology, arousal) and their impact on cognition.

12 **200.012** Implicit Attitudes Towards Adults with Autism: A Multi-Study Investigation

***J. Zeman**, C. L. Dickter and J. Burk, College of William and Mary, Williamsburg, VA*

Background: Research examining attitudes towards individuals with autism has primarily relied on self-report measures that explicitly ask about attitudes and thus, may be subject to bias, particularly social desirability effects. Further, the majority of these studies have assessed perceptions of children rather than adults with autism. Given the increasing numbers of people with autism, it is important to develop a better understanding of attitudes towards adults with autism by their peers and other adults. Using measures of both explicit and implicit attitudes will provide a more comprehensive view of attitudes towards adults with autism.

Objectives: The goal of this research was to develop an Implicit Association Test (IAT) to assess implicit attitudes towards people with autism.

Methods: Participants in Study 1 were 175 college students (63 males; M_{age} = 19.15 years, 50.0% White). In Study 2, participants were 94 individuals (50 males; M_{age} = 31.3 years, 66.0% White) who were recruited through Amazon MTurk. There were 127 participants in Study 3 (75 males; M_{age} = 33.4 years) who were also recruited from Amazon MTurk. All participants completed a modified version of the IAT (Nosek et al., 2002) that we developed to assess attitudes towards autistic and neurotypical individuals. In Studies 1 and 2, the descriptors used in the IAT included positive and negative stereotypes that pre-test participants had identified as describing autistic and non-autistic adults. In Study 3, the words selected to describe autistic and non-autistic adults were descriptive rather than stereotypical (i.e., autistic, spectrum, non-autistic). Participants also completed two questionnaires that assessed explicit attitudes towards autism: the Autism Quotient questionnaire (Baron-Cohen et al., 2001), and the 16-item Societal Attitudes towards Autism Scale (Flood et al., 2013).

Results: University students (Study 1) and individuals from the general U.S. population (Studies 2 and 3) showed a negative implicit bias against their autistic peers, with students having the most bias, and the adults in Study 3 having the least bias. Across all studies, the fewer autistic behaviors participants reported, the more negative their implicit bias was against people with autism. The findings indicated that across all three studies, the responses to the explicit measures indicated positive attitudes towards individuals with autism. Further, the associations between the implicit and explicit measures were non-significant within each study.

Conclusions: Across three different samples from two different populations, the findings reveal that the participants have negative implicit attitudes towards persons with autism, although reporting positive explicit attitudes. The social desirability bias inherent in explicit measures is apparent in these findings. These results may provide insights concerning why individuals with autism report experiences of discrimination such as social exclusion, humiliation, and neglect (e.g., Peyton, 2004). Universities, workplaces, and other organizations may need explicit facilitation to make their environment more welcoming to adults with autism.

13 **200.013** In Their Own Words: Associated Features in Intellectually Able Adult Males and Females with Autism Spectrum Disorder (ASD)

***K. A. Loveland**[1] and A. Krishnan[2], (1)Department of Psychiatry and Behavioral Sciences, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX, (2)Purdue University, West Lafayette, IN*

Background:

Adults with ASD can experience difficulties not limited to the primary criteria for diagnosis of ASD. We sought to examine associated features that verbally able adults report about themselves, and in particular, whether there are differences by gender in the type and severity of features reported. Qualitative information about associated features reported by outpatients with ASD was compiled to develop a questionnaire including 51 statements (Adolescent and Adult Autism Spectrum Checklist – AAASC). (See Table 1).

Objectives:

1) To determine which associated features were most highly rated in our sample, 2) To determine whether mean scores were associated with scores on other widely used self-report measures for assessment of adult ASD, 3) To compare findings on male and female respondents.

Methods:

The AAASC was rated by 107 individuals with ASD (37.5% female; 73.7% Euro American; 44.7% 18 – 30 y/o; 55.3% 31-71 y/o) seen at a clinic

specializing in adult ASD diagnosis and intervention. Statements were rated on a 0 -5 scale where 5 was highest. For analysis the statements were grouped in four content areas: Preference for Sameness and Routine; Cognitive Style and Executive Functioning; Difficulties in Conversation; Social Awareness and Expectations.

Mean values for each content area were calculated, and five items with mean ratings lower than 2.0 were removed from further analysis. The remaining 46 items in their four groupings were examined first for their relative frequency, then for the association of their mean scores with scores on the *Social Responsiveness Scale, 2nd Edition* (SRS-2), *Autism Quotient* (AQ), *Empathy Quotient* (EQ), and *Ritvo Autism Asperger Diagnostic Scale-Revised Version* (RAADS-R). Mean scores were then examined using multivariate analysis of variance, with chronological age covaried, to examine differences by gender.

Results:

For the sample as a whole, items associated with Preference for Sameness and Routine were rated highest, followed by Cognitive Style and Executive Function, Difficulties in Conversation, and Social Awareness and Expectations, respectively (Table 1). Multiple regression revealed that total scores on the SRS-2, RAADS-R, and AQ were strongly related to some or all of the 4 groupings, and the EQ only to Preference for Sameness and Routine (Table 1). Results of the MANOVA were statistically significant (Wilks Lambda = .871; F (4, 95) = 3.53, p=.01) for differences by gender. Tests of between subjects effects found that females reported significantly higher levels of associated features in all categories than did males (Preference for Sameness and Routine, p=.024; Cognitive Style and Executive Functioning, p=.05; Difficulties in Conversation, p=.002; Social Awareness and Expectations, p=.001).

Conclusions:

The associated features reported by adults with ASD were highly congruent with existing self-report measures of ASD characteristics. It is of note that adults with ASD frequently endorsed problems that reflect cognitive differences, especially in executive function, an area not typically assessed on ASD measures. Interestingly, women reported significantly higher levels of problems than men across content areas. They may experience their problems as more severe, or they may be more willing to report on problems.

14 **200.014** Insights from a Qualitative Analysis of Sexual Minority-Identifying Individuals with Autism Spectrum Disorder

L. R. Qualls[1,2], *T. Raffale*[3] *and K. Hartmann*[2], *(1)Virginia Consortium Program for Clinical Psychology, Norfolk, VA, (2)Eastern Virginia Medical School, Norfolk, VA, (3)The Catholic University of America, Washington, DC*

Background: Individuals with Autism Spectrum Disorder (ASD) are more likely to endorse a sexual minority orientation than those with typical development (TD, DeWinter et al., 2017). However, no empirical studies have examined factors that contribute to higher rates of sexual minority orientation in ASD. A biopsychosocial model has been proposed for sexual orientation development in TD individuals (Dillon, Worthington, & Moradi, 2011). This model may have applicability to sexual minority orientation development in individuals with ASD, but this has yet to be explored. Qualitative data analytic methods may yield insights into whether these factors capture the unique experiences of sexual minority individuals with ASD.

Objectives: 1) Identify themes related to sexual minority orientation in individuals with ASD and 2) compare themes to extant model for TD.

Methods: Eleven participants with ASD ages 18-30 (mean age 23.5; 7 female, 3 non-binary, 1 male; 8 Caucasian, 1 Asian, 1 African-American, 1 Other) who identified as sexual minorities provided qualitative responses to questions related to sexual minority orientation development either in person (*n*= 1) or through an online questionnaire (*n*= 10). Questions were based on the six factors of the model or on other relevant themes identified in the literature (openness to discussing sexuality, characteristics of participant's romantic and sexual relationships). The data were examined using thematic analysis: responses were double-coded by the first two authors into groups based on which of the theoretical themes they best represented. Data that were judged by both coders to not fit one of the relevant theoretical themes were grouped together under a new theme.

Results: A total of ten themes emerged from the data. Eight were theoretical themes (biology, microsocial context, culture, religious beliefs, gender norms, socialization, systematic homonegativity, openness to discussing sexuality, and relationship characteristics)and two were inductive themes that emerged from the data (being a sexual minority with autism and sexual orientation). Participants reported unique experiences with regards to minority identification and polyamory. For example, participants noted that social differences made it difficult for them to find other sexual minority individuals to interact with, and that language difficulties and lack of exposure to other sexual minority individuals made it harder for them to conceptualize their identities.

Conclusions: Overall, the experiences of sexual minority individuals with ASD were similar to those of TD sexual minority individuals in relation to the model of sexual orientation development. However, participants indicated that characteristics of ASD sometimes made expression and communication of their sexual minority identity difficult. Experiences with polyamory, the interaction of language with identifying and understanding their sexual minority orientation, and other interactions between autism and sexual orientation are aspects of the experience of individuals with ASD that have not yet been researched. Using qualitative designs which ask questions directly of adults with ASD is an effective way to capture aspects of their lived experiences that may not be articulated in quantitative, survey-based research studies. Additionally, using online data-collection methods appears to be especially effective.

15 **200.015** Interviewing Autistic Adults: Adaptations to Support Recall in Police, Employment, and Healthcare Interviews

J. E. Norris[1], *L. Crane*[2] *and K. L. Maras*[3], *(1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, (3)Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background:

Recounting past experiences is a crucial feature of most formal social interactions, including when being interviewed for a job or in the Criminal Justice System (CJS), during a health or social care consultation, or as part of assessments for welfare. During such interviews we usually need to recall personal memories of specific episodes, which can be difficult for autistic adults under standard questioning structures (e.g., open questioning).

Objectives:

There is little research into methods of facilitatingautistic adults' recall outside of lab-based memory tasks. The current study aimed to investigate this within the framework of the 'Task Support Hypothesis' (Bowler et al., 1997) by testing the efficacy of interview prompting techniques in supporting autistic adults' recall of specific personal memories.

Methods: Based on an a-priori sample size calculation (assuming α =.05), in order to achieve Cohen's (1992) recommended power of .80 to detect a medium-to-large effect size, 32 ASD and 31 typically developing (TD) participants were recruited. Participants were asked to recall specific instances from their past that were relevant to CJS, healthcare, and employment interviews. Eighteen questions were split into three blocks: (1) OPENquestions (e.g., "Tell me about a specific instance when you have been to the supermarket"); (2) SEMANTIC SUPPORT- general personal memories were prompted first to support recall of a specific instance (e.g., "are you a worrier?" ... "Tell me about a specific instance when you have felt worried"); (3) VERBAL LABELS - participants received a visual pie-diagram with prompts to recall: When? People? Actions? Setting? Objects? Half of the participants also received preparatory information which included the question topics. The study used a mixed factorial design: 2 (Autistic, TD) x 2 (Preparation, No Preparation) x 3 (Support: Open, Semantic Support, Verbal Labels), where Support was within-subjects

Results:

Participants' interview answers were coded for *specificity*(level of specific detail provided) and *relevance* (number of episodically and semantically relevant details recalled).

Specificity- autistic participants recalled less specific memories overall ($F(1, 55) = 5.58$, $p = .022$, $n_p^2 = .09$). Specificity was improved for both groups in the Verbal Labels condition($F(2,110) = 14.39$, $p < .001$, $n_p^2 = .21$). Answers to CJS questions were more specific than those for health and job questions ($F(2, 110) = 24.20$, $= p < .001$, $n_p^2 = .31$). Employmentquestions were particularly difficult for autistic participants (Context*Group: $F(2, 110) = 3.14$, $p = .047$, $n_p^2 = .05$). Finally, when answering job questions, semantic support aided autistic participants to recall a more specific memory (but not for health and CJS; Support*Context*Group:$F(4, 220) = 3.28$, $p = .012$, $n_p^2 = .06$).

Preliminary analyses also indicate that question support facilitates recall of more episodically-relevant details.

Conclusions:

Autistic participants recalled less specific memories overall, and struggled with job questions in particular. Verbal labels provided the most effective support for specificity. The findings will inform interviewing professionals about methods they can use to facilitate communication with autistic adults. The results provide further evidence for the task support hypothesis (Bowler et al., 1997).

16 **200.016** Facial First Impressions of Neurotypical Adults with Varying Degrees of Autistic Traits

D. W. Tan[1], *M. T. Maybery*[1], *L. Ewing*[2] *and A. J. Whitehouse*[3], *(1)School of Psychological Science, University of Western Australia, Perth, Australia, (2)University of East Anglia, Norwich, United Kingdom, (3)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia*

Background:

Recent studies suggest that there are structural differences in facial morphology that are related to ASD and autistic traits in the general population. An extension of this research is the study of facial first impressions formed by people around autistic individuals. Facial first impressions are typically formed quickly and intuitively, and they tend to influence the quality of social interactions. Several studies found that neurotypical individuals consistently formed less favourable first impressions of autistic persons compared to those of non-autistic individuals. At present, it is unclear whether the relationship between ASD and negative first impression extends to neurotypical individuals with different degrees of autistic traits.

Objectives:

The present study aims to examine whether facial first impression ratings of neurotypical adults vary according to levels of autistic traits.

Methods:

Stimulus Participants

A total of 1,995 undergraduate students completed the autism-spectrum quotient (AQ). Students aged between 18 and 25 yrs, and with an AQ score that fell in the bottom, middle and top 15% of the distribution were invited to participate further in this study. Fifty-four Caucasian men and 54 Caucasian women had their facial photographs taken under standardised conditions (e.g., neutral facial expressions, make-up free).

Raters

An additional group of 53 raters (mean age = 20.6 yrs; 38 females) were recruited to provide first impression ratings on a 10-point slider scale in response to four items: (1) Social: *How likely is it that this person is socially awkward?* (2) Get Along: *How likely is it that this person gets along well with others?* (3) Hang Out: *How likely is it that you would hang out with this person in your free time?* (4) Start Conversation: *How likely is it that you would start a conversation with this person?*

Results:

For women, repeated measures ANOVA revealed that relative to those who scored low on the AQ, women with high AQ scores consistently received less favourable first impression rating across all four items—Social: $F(2,104) = 24.6$, $p < .001$, $\eta_p^2 = .32$; Get Along: $F(2,104) = 23.8$, $p < .001$, $\eta_p^2 = .31$; Hang Out: $F(2,104) = 35.8$, $p < .001$, $\eta_p^2 = .41$; Start Conversation: $F(2,104) = 25.8$, $p < .001$, $\eta_p^2 = .33$.

In contrast, compared to men with low AQ, men with high AQ scores consistently received more favourable first impression ratings across the four items: Social: $F(2,104) = 4.4$, $p = .002$, $\eta_p^2 = .08$; Get Along: $F(2,104) = 31.7$, $p < .001$, $\eta_p^2 = .38$; Hang Out: $F(2,104) = 26.8$, $p < .001$, $\eta_p^2 = .34$; Start Conversation: $F(2,104) = 12.0$, $p < .001$, $\eta_p^2 = .19$.

Conclusions:

The current findings suggest that increased autistic traits are related to less favourable first impressions in women but more favourable first impressions in men. Our lab group has previously published a study reporting increased facial masculinity in high-AQ women and reduced facial masculinity in high-AQ men (Gilani et al.,2015). Taken together, these findings imply that more masculinised facial structures in high-AQ women may be linked to less favourable impressions formed while less masculinised structures in high-AQ men may be associated with more favourable first impressions.

17 **200.017** Longitudinal Trajectories of the Behavioral and Health Phenotype of Adolescents and Adults with Fragile X Syndrome

ABSTRACT WITHDRAWN

Background: Individuals with fragile X syndrome (FXS) display behavior problems, functional limitations, and health problems across the lifespan (Smith et al., 2016; Raspa et al., 2010). However, much of what we know about the phenotype comes from cross-sectional studies investigating children and adolescents.
Objectives: To use longitudinal data to examine ten-year trajectories of behavior (daily living skills and behavior problems) and health (body mass index [BMI] and number of health conditions) in adolescents and adults with FXS, accounting for sex and autism spectrum disorder (ASD) symptoms.

Methods: Participants (n = 134) were drawn from a longitudinal study of families of adolescents and adults with FXS (Mailick et al., 2014). At study entry, individuals with FXS met three criteria: 1) were 12 years of age or older, 2) had received a diagnosis of FXS, and 3) lived with parents or had at least weekly contact. If there was more than one co-residing child, mothers reported on the child she viewed as most severely affected. Individuals with FXS were mostly males (85.1%), in their 20s on average (M = 20.19, SD = 6.92, range 12–48 years), and most lived with mothers (90.3%). About one-quarter (24.2%) of the sample had a co-occurring diagnosis of ASD. Mothers reported on sons' or daughters' daily living skills, behavior problems, height and weight, and number of health conditions, as well as lifetime ASD symptoms. The present sample was restricted to those with intellectual disability.

Results: Hierarchical linear modeling was used to describe change in the behavioral and health phenotype of adolescents and adults over ten years and to examine effects of between-person differences in sex and ASD symptomatology on trajectories. We evaluated separate growth curve models for four outcomes: daily living skills, behavior problems, BMI, and health conditions. Sex and lifetime ASD symptoms at Time 1 were entered as predictors of the intercept and the linear and quadratic slopes. Results indicated increased independence in daily living skills and decreases in behavior problems improved over time. However, BMI increased over time, indicating a greater proportion of individuals meeting the cutoffs for overweight or obesity across the course of the study. The number of health conditions also increased over time. Adolescents and adults who started with fewer ASD symptoms were more independent in daily living skills and had fewer behavior problems.

Conclusions: This is the first study to examine longitudinal trajectories of behavioral and health phenotypes for adolescents and adults with FXS over the course of a decade. Trajectories for daily living skills and behavior problems indicated improved over time. Individuals with elevated levels of ASD symptoms were at risk for lower levels of independence in daily living and more behavior problems at the initial time point than were those with lower levels of ASD symptoms, suggesting possible targets for intervention.

18 **200.018** Measuring Autistic Adults' Healthcare Self-Efficacy, Visit Preparedness, and Use of Accommodations

C. Nicolaidis[1], *D. Raymaker*[1], *L. A. Croen*[2], *K. Y. Zhen*[1], *S. K. Kapp*[3], *J. Lee*[1], *M. Weiner*[4] *and A. Urbanowicz*[5], *(1)School of Social Work, Portland State University, Portland, OR, (2)Division of Research, Kaiser Permanente, Oakland, CA, (3)University of Exeter, Exeter, United Kingdom, (4)Center for Health Services and Outcomes Research, Indiana University, Indianapolis, IN, (5)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, Queensland Centre for Intellectual and Developmental Disability, South Brisbane, Australia*

Background: Autistic adults report greater unmet healthcare needs, lower satisfaction with patient-provider communication, and greater barriers to healthcare than non-autistic adults. Qualitative data suggest that potential interventions to improve healthcare outcomes may work by helping patients prepare for visits, increasing their self-efficacy in managing their health and healthcare, and ensuring that they receive the accommodations they need. However, there are no validated instruments for measuring such constructs.
Objectives: Develop and psychometrically test three new scales: the Confidence in Managing Health and Healthcare Scale (CMHHS), the Visit Preparedness Scale (VPS), and the Provider and Staff Use of Accommodations Scale (PSUAS).

Methods: We used a community-based participatory research approach throughout the project, in partnership with academic researchers, autistic adults, family members, and healthcare providers. We used our prior qualitative research to create the 21-item CMHHS, the 6-item VPS, and the 8-item PSUAS. Each scale has two versions – one for use with autistic adults directly, and another for supporters. We collaborated with community partners to ensure content validity. This analysis used baseline data from an ongoing study to assess the effectiveness of a primary care intervention on healthcare outcomes for autistic adults. We administered the baseline survey online or the telephone to 244 autistic adults recruited from 8 primary care clinics in Oregon and California, USA. All participants had medical diagnoses on the autism spectrum. Among them, 194 participated directly, and 50 participated via a supporter. Participants had a mean age of 30 years (range 18-72); 70% were male; and 62% were non-Hispanic white. Thirty-nine percent often or always, 24% sometimes, and 38% rarely or never needed assistance in healthcare settings. Thirty-eight percent reported a co-occurring chronic physical health condition, and 61% reported a co-occurring mental health condition. We assessed the scales' internal consistency reliability using Cronbach's alpha, and convergent validity using pair-wise correlations and t-tests.

Results: Community partners ensured that items were easy to understand and captured the intended construct. Both versions of all three scales had good to excellent internal consistency reliability, with alphas ranging from 0.81 to 0.96. The scales showed convergent validity in the expected directions. Participants who reported unmet healthcare needs had lower confidence in managing their health and healthcare (p= 0.0002), felt less prepared for healthcare visits (p=0.006), and were less likely to receive necessary accommodations (p=0.0001). There were strong positive correlations between satisfaction with patient-provider communication *and* healthcare self-efficacy (r=0.47, p<0.0001); visit preparedness (r=0.55, p<0.0001); and use of accommodations (r=0.52 p<0.0001). There were negative correlations between barriers to healthcare *and* healthcare self-efficacy (r=-0.53, p<0.0001); visit preparedness (r=-0.44; p<0.0001); and use of accommodations (-0.32; p<0.0001).

Conclusions: The three new measures demonstrated strong internal consistency reliability and convergent validity with unmet healthcare needs, satisfaction with patient-provider communication, and barriers to care. Future research is needed to validate these scales in additional populations, to assess whether interventions improve healthcare outcomes, and to test whether they do so via these hypothesized mechanisms of action.

19 **200.019** Neurodiversity Career Initiatives Should Encompass Diverse Careers: Insights from a Participatory Study with Autistic and Non-Autistic College Students

C. Cheriyan[1], *W. Long*[2], *P. Y. Choudhury*[1], *N. Tricarico*[3], *J. Rivera*[4], *A. Riccio*[5], *D. DeNigris*[6], *P. J. Brooks*[7] *and K. Gillespie-Lynch*[8], *(1)CUNY, NY, NY,*

(2)Psychology, College of Staten Island, CUNY, Staten Island, NY, (3)College of Staten Island, City University of New York, Staten Island, NY, (4)CUNY, Staten Island, NY, (5)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (6)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (7)Psychology, College of Staten Island, Staten Island, NY, (8)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY

Background: Autistic youth are *less* likely to enroll in college or obtain employment than people with other disabilities (Shattuck et al., 2012). However, those who enter college are *more* likely to enroll in STEM majors than students without disabilities (Wei et al., 2013). Growing recognition that many autistic people are drawn to STEM has sparked promising technology-focused neurodiversity employment initiatives (e.g., Specialisterne). Yet, autistic people remain chronically underemployed, and those who obtain jobs work fewer hours for less pay than people with other disabilities (Cimera & Cowan, 2009). Social challenges, difficulties adapting to change, and stigma impact employment success (Pfieffer et al., 2017). To help autistic people overcome these barriers, researchers recommend aligning employment opportunities with their interests (Hendricks, 2010). However, little is known about their career interests/goals. One online study used Holland's career interest categorizations to compare 136 autistic (63% female) and 155 non-autistic (59% female) participants. Autistic participants endorsed realistic, investigative, and conventional interests more and social and enterprising interests less than non-autistic participants (Lorenz & Heinitz, 2014). Like other online studies (e.g., Gillespie-Lynch et al., 2017), autistic females were overrepresented in the sample. No prior research has examined career goals/interests among autistic college students in particular.

Objectives: To compare the career goals/interests of autistic and non-autistic college students. One of the autistic co-authors/coders initiated this focus.

Methods: Autistic students (*n* = 27; 92.6% male; 64.0% White; *M* = 21.23 years) in a participatory mentorship program and non-autistic students (*n* = 33; 39.4% male; 30.0% White; *M* = 21.15 years) from a subject pool answered open-ended questions: What would you like to do: 1) right after college; 2) five years after college? Responses were coded after establishing reliability. Autistic students and a larger subject pool sample of non-autistic students (*n* = 255; 25% male) completed an adaptation of Holland's career interests inventory (Liao et al., 2008) on O*NET, receiving 3 of 6 possible career interest classifications (Table 1).

Results: Autistic students did not differ from non-autistic students in career goals (Table 2). When gender, age and autism were entered as predictors of career goals in binary logistic regressions, *only* being *older* predicted specific and high-status career goals (*ps* < .04). Autistic students received Enterprising classifications *less* frequently (32%) than non-autistic students (55%, Table 1). No other interests differed by autism status. Gender predicted social (favoring women), conventional and realistic (both favoring men; *ps* < .04) career interests.

Conclusions: Autistic and non-autistic college students expressed similar career aspirations. Autistic students expressed less interest in enterprising careers. Contrary to popular representations of autism, many autistic students expressed social career interests. This finding aligns with recent evidence that autistic people in Germany are most likely to work in "health and social sector, teaching and education" fields (Frank et al., 2018). Use of career interest inventories early in college may help autistic students identify skills (e.g., time management, adapting to unspoken expectations at work) that they may need help developing to obtain jobs well-matched to their interests.

20 **200.020** Next Steps – Improving Adult Transition Outcomes through Parent/Family Education and Empowerment

A. M. Valdez[1], *L. Frederick*[2], *G. Stobbe*[1,3], *D. Eaton*[1], *M. Pullmann*[4] *and J. Locke*[2], *(1)Psychiatry & Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA, (2)Speech & Hearing Sciences, University of Washington, Seattle, WA, (3)Neurology, University of Washington, Seattle, WA, (4)Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA*

Background:

Within the next 15 years, an estimated 500,000 children in the United States with autism spectrum disorder (ASD) will enter adulthood. Additionally, there has been limited research into adult services and outcomes. As a result, a challenge faces clinicians in providing families with evidenced-based transition tools in a manner that allows caregivers to build resiliency in becoming creative and flexible consumers for their young adult children. We have developed and implemented three consecutive 90-minute classes entitled "Next Steps," focused on educating caregivers about transition related topics in small group settings. (See Figure 1. Curriculum Content). We have successfully conducted this class over the past 5 years and 205 families have participated.

Objectives:

To assess the impact of Next Steps classes on family empowerment and readiness for transition to adulthood.

Methods:

Course evaluations were collected from 13 families before and after the classes over 3 class cohorts to evaluate the impact of the Next Steps training on the Family Empowerment Scale. A survey questionnaire called Transition Daily Rewards and Worries Questionnaire (Glidden & Jobe, 2007) was also used.

Results:

On the Family Empowerment Scale, there was a statistically significant increase in the mean scores of the Service System subscale before Next Steps training (M = 44.38, SD = 6.23), and after training (M = 48.00, SD = 6.95). The mean increase in Service System subscale scores was 3.62 with a 95% confidence interval ranging from -6.77 to -.46. The Service System subscale is characterized as parental interactions with service systems to attain services needed by their child (Koren, Dechillo, and Friesen, 1992). The Service System subscale consisted of questions like, "My opinion is just as important as professionals' opinions in deciding what services my child needs." On the Transition Daily Rewards and Worries Questionnaire, there was a statistically significant increase in the mean scores of the Positive Future Orientation subscale before Next Steps training (M = 18.00, SD = 5.61), and after training (M = 21.31, SD = 9.92). The mean increase in Positive Future Orientation subscale scores was 3.31 with a 95% confidence interval ranging from -5.79 to .82. The Positive Future Orientation subscale is defined by general feelings of the parent surrounding their child's future (Burke, Fisher, & Hodapp, 2012). The Positive Future Orientation subscale consisted of questions like, "I am confident that my child will be okay even after I die."

Conclusions:

Transition to adulthood for individuals with autism poses unique challenges to caregivers. Administering transition-related curriculum in small group settings helps to empower families in accessing services and feeling more positive about the future. Future directions include improving

our understanding of long-term impact of course participation, broadening delivery of the Next Steps to include non-English speaking families and including patients along with their caregivers in the Next Steps classes.

21 **200.021** Oral and Dental Healthcare of Autistic and Non-Autistic Adults

J. Granich[1], *A. Urbanowicz*[2], *A. O. Whitehouse*[3], *N. G. Lennox*[4] *and P. Brahmbhatt*[5], *(1)Telethon Kids Institute, Telethon Kids Institute, Subiaco, Australia, (2)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, Queensland Centre for Intellectual and Developmental Disability, South Brisbane, Australia, (3)Telethon Kids Institute, The University of Western Australia, Perth, Western Australia, Australia, Perth, Australia, (4)MRI/UQ, The University of Queensland, Brisbane, QLD, Australia, (5)The University of Queensland, Brisbane, Australia*

Background: Oral health is an integral part of health and well-being which impacts on quality of life. Adults on the spectrum maybe at a higher risk of poor oral health compared to adults not on the spectrum due to the nature of the neurodevelopment condition, high rate of comorbidities or limited adaptive skills. Little is known about the oral and dental healthcare of autistic adults which limits the capacity for any intervention.
Objectives: To 1) examine oral hygiene practices 2) identify dental needs 3) examine dental visit experiences and 4) identify barriers to accessing professional dental care in autistic and non-autistic adults.

Methods: We developed an online survey to better understand oral and dental health of autistic adults in Australia, in comparison to a general adult population. Survey items asked about socio-demographics, oral hygiene practices, dental problems and dentist visit experience including barriers to dental care and services. The Autism Quotient (AQ) was included as a diagnostic proxy for autism spectrum disorder. Autistic adults either self-completed or sought assistance from a substitute decision maker to complete the survey. Twenty six autistic adults and 21 non-autistic adults completed the survey.

Results: Autistic adults were significantly older than non-autistic adults (36.7 vs 23.1 years, p = .001). Across both groups, most adults held degree qualifications and were single. The AQ among autistic adults was significantly higher compared with non-autistic adults (38.4 vs 17.3, p = .001). Daily oral hygiene practices did not differ significantly across the two groups for tooth brushing. Over 40% of autistic adults reported oral/dental problems compared to 9% non-autistic adults (p = .015). Dental decay and tooth sensitivity were the most commonly reported problems while sensory sensitivities made dental visits more difficult for autistic adults compared with non-autistic adults (p = .001). Oral instrumentation, bright lights and smells were reported as significant challenges for autistic adults as well as perceived feelings of being afraid to go to the dentist for routine dental cleaning. However, no significant differences emerged between the two groups for how often they visited the dentist.

Conclusions: Autistic adults' oral hygiene practices are similar to non-autistic adults in the Australian community. Dental decay and tooth sensitivities appear to be an unmet dental need among autistic adults. Although the frequency of dental visits was similar to those of non-autistic adults. Sensory sensitivities posed as barriers to dental care whilst fear about teeth cleaning may further compromise the dental visit experience among autistic adults. Although this preliminary study requires exploration, the results suggest preparatory or supporting preventative dental interventions may be beneficial to autistic adults. The findings have implications for future research into clinical dental health care of autistic adults including psycho-educational strategies which may assist them in overcoming sensory sensitivities or dental fear.

22 **200.022** Parent-Child Interactions in Families of Adults with Autism Spectrum Disorder during an Intervention Focused on Increased Social and Adaptive Functioning

J. B. McCauley[1,2], *T. Oswald*[3], *S. Ruder*[1], *A. C. Stahmer*[4] *and M. Solomon*[5], *(1)UC Davis MIND Institute, Sacramento, CA, (2)UCLA Semel Institute, Los Angeles, CA, (3)University of California at Davis MIND Institute, Sacramento, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (5)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA*

Background: Research on adults with autism spectrum disorder (ASD) has found that a significant proportion of these individuals struggle to attain independence, and continue to live with their parents well into adulthood. Yet, we know little about relationships between adults with ASD and their parents, and the few studies to date have relied solely on parent-report questionnaires and interviews assessing parent perspectives when investigating their associations with young adult outcomes. This is a clinically important gap in our knowledge as enhancing the understanding of parent-young adult relationships may aid in the development of treatments for adults with ASD.
Objectives: The current pilot study is the first to use observational coding to assess positivity and control during parent-young adult discussions regarding autonomy, and to examine how the correlates of these relationship characteristics are associated with change during the course of a recently published intervention to enhance coping and adaptive skills in young adults with ASD.

Methods: Eleven adults with ASD (aged 18 – 39) were recruited from the wait list of an ongoing randomized control trial designed to improve coping skills and adaptive skills (Oswald et al., 2017). Adults and one parent engaged in a standardized discussion task with their parents and were given assessments of adaptive behavior (Adaptive Behavior Assessment-3rd Edition, Harrison & Oakland, 2003; Adult Behavior Checklist, Achenbach & Rescorla, 2003) before and after receiving the intervention. The discussions were coded with the Iowa Family Rating Scales (Melby et al., 1998) for levels of parent and child positivity and controlling behavior.

Results: There was high levels of baseline positivity in both parents and adults with ASD. Levels of controlling behaviors in dyads (e.g., behaviors that served to control, influence, or dominate the opinions, actions, or points of view of others) were negatively associated with changes in levels of adult adaptive functioning. Specifically, controlling behaviors observed in dyads before intervention were negatively associated with growth on conceptual adaptive behaviors—which consist of items regarding an individual's academic, communicative, and self-direction skills ($r_s(9)$ = -.66, p = 0.03). The association with growth on adaptive behavior was similar for both parent and child control (see Figure 1).

Conclusions: Higher levels of control during conversations about autonomy may prevent adults from making improvements in the skills required to attain independence. Perhaps, in consideration of their children's strengths and difficulties, parents of adults with ASD may feel the need to more closely guide their young adult's behavior by lecturing or directing their thinking about how to live independently. However, parents who use controlling communication may be limiting their young adults' ability to develop decision-making and self-direction skills. Findings emphasize the need to better understand features of the parent-child relationship and their association with the functioning of young adults with ASD. This is especially true given that the emerging literature indicates that interventions targeting self-determination and coping skills appear to be most effective for promoting optimal outcomes in young adults with ASD (Hume, Loftin, & Lantz, 2009; Oswald et al., 2017; Palmen, Didden &

Lang, 2012).

23 **200.023** Patient-Provider Communication Gap: Barriers to Healthcare for Patients with Autism Spectrum Disorder

L. O. Lavoura[1], *N. Bianculli*[1], *C. C. Mann*[2] *and O. Ghoneim*[1], *(1)School of Pharmacy and Physician Assistant Studies, University of Saint Joseph, Hartford, CT, (2)Department of Counseling and Applied Behavior Analysis, University of Saint Joseph, West Hartford, CT*

Background:

Difficulties in social interactions characteristic of an Autism Spectrum Disorder (ASD) diagnosis may make navigating the healthcare system challenging, therefore, having healthcare providers in all sectors of healthcare that are confident and competent in communicating with patients with ASD is paramount.

Preißmann (2017) reported that many providers lack the knowledge, skills and confidence to work with individuals with ASD, which can lead to refusal to treat. Thus, there remains a considerable discrepancy between the number of individuals with ASD seeking medical care and the number of healthcare professionals willing/capable/trained to provide care to them, which might result in long waiting periods, and delays in diagnosis and treatment of medical conditions. Identifying the communication gap between patients with ASD and their healthcare providers is a key to minimize the barriers to healthcare for patients with ASD.

Objectives:

The purpose of this study is to collect healthcare professionals' perspective on the current barriers to healthcare for patients with ASD, and the need to develop a patient-provider communication instrument/tool that takes in consideration the social skills and language/communication level of patients with ASD.

Methods:

An online questionnaire (designed by the research team and approved by the Institutional Review Board) was distributed to healthcare professionals who provide direct patient counseling at their practice. Invitation to participate was sent to hospitals, clinics, private pharmacies, dental clinics, and healthcare associations in the Northeast United States with a link to the questionnaire. The questionnaire consists of 18 items (4 demographics, 7 multiple choice, 2 Likert-scale, 5 open-ended). Information regarding the practice type, years of experience and type of health care setting was collected. Additionally, information on additional degrees, certificates or training the participants might have received on their own or through their institutions was also gathered.

Results:

116 participants completed the online questionnaire. The majority (62.9%) were pharmacists, followed by (22.4%) nurses, and females (69.8%) followed by males (29.3%). Practice setting varies with 54.3% came from an inpatient hospital setting, 14% at community pharmacy, 13.8% at outpatient hospital setting. Years of experience span from less than 5 years (31%) to greater than 20 years (26.7%). Although 10.3% indicated they are comfortable in communicating with patients with ASD, only 4.3% indicated they are prepared to provide patients with ASD quality care, and only 3.4% had additional training, certificates related to help them prepare to provide patients with ASD quality care. 78.8%, 86.7%, 68.1% feel that having additional training, continuing education and communication aids will improve the quality of care they provide to patients with ASD.

Conclusions:

Information from the questionnaire pointed several barriers to healthcare for patients with ASD, and the need to developing an innovative communication aid/tool as an exchange between the patient and the healthcare provider. The communication aid will be piloted in the next phase of this research, taking in consideration the social skills, and language/comprehension level of patients with ASD.

24 **200.024** Prevalence, Correlates and Predictors of Good Outcomes in Autism Spectrum Disorder in Late Childhood

ABSTRACT WITHDRAWN

Background: The outcome literature in ASD has focussed largely on changes in symptoms and cognitive skills over relatively short time frames with few data points. There are very few studies that investigate what constitutes a 'good' outcome in late childhood in ASD. This is an important developmental stage as health status at this stage is often more stable compared to earlier periods and predicts health status at later ages. Objectives: To describe the process whereby parents defined domains to be assessed in measuring good outcomes and to describe the prevalence, agreement, correlates and predictors of good outcomes in children with ASD at 8-11 years of age followed longitudinally from 2-4 years of age.

Methods: Data are drawn from the Pathways in ASD study which assembled an inception cohort of children with ASD (N=421) soon after the diagnosis was given at between 2- 4 years of age. The children were seen at several time points and this presentation will focus on outcomes investigated at 8-11 years of age. Multiple domains of a good outcome were defined by parents who identified socialization, communication, independence, and emotional challenges as key domains. These domains were measured using the Vineland Adaptive Behaviour Scales and the CBCL. A 'good outcome' in these domains was defined by scoring in the 'typical' range on any instrument or by an improvement of one standard deviation in standardized scores between the two time points. The prevalence of a good outcome in each domain by either metric was calculated, the agreement between good outcomes definitions was calculated, and the predictors of these outcomes were assessed

Results: The prevalence of a good outcome on any of the 5 domains ranged between 4 and 26% depending on the domain and the metric. There was little agreement between the different ways of defining a good outcome or between different outcome domains, even within a measurement tool. In particular there was no agreement (beyond chance) between the good outcomes defined by scores in the typical range and good outcomes defined by improvement in key domains. A good outcome defined by either metric was associated with lower ASD symptom scores, higher IQ scores and more friendships in late childhood. Important contextual factors such as family functioning were important predictors of a good outcome, controlling for baseline scores.

Conclusions:

The results suggest that there are multiple ways of defining a good outcome that individualy are not uncommon in this cohort during late childhood. Given the heterogeneity seen in ASD, it is possible to arrive at a 'good' outcome by multiple pathways, either by achieveing a typical

score or by showing clinically significant improvement. Although these ratings of outcome were based on parental input, we do not have the perspective of children with ASD which will be crucial in future studies. In addition, the stability of a good outcome in unknown. The different domains of outcome appear to be relatively independent suggesting that interventions must be broadly based to ensure improvement across multiple domains.

25 **200.025** Program Evaluation of a Community Organization Supporting Employment for Adults with ASD

V. Martin *and M. J. Lanovaz, École de psychoéducation, Université de Montréal, Montreal, QC, Canada*

Background: Action main-d'oeuvre (AMO), a community organization in Montreal (Canada), offers services for adults with ASD looking for employment. To receive services, clients must have a documented diagnosis of ASD, be motivated to work, be independent for transportation and have the potential to enter the competitive labour market. Counsellors support their client's job search and may assess potential jobs and workplaces. AMO offers direct support in the workplace for training, for developing adaptations, and for raising awareness of supervisors and colleagues about ASD, as needed. They can also be called upon to resolve issues in the workplace.
Objectives: The main objective of our study is to assess the characteristics of AMO's clients as well as the impact of their services on job integration.

Methods: All new clients between January 2017 and October 2018 were invited to participate in our study. Participants filled out questionnaires about their symptoms of autism, their adaptive skills, their work self-efficacy and their anxiety. AMO's database provided socio-demographic data, information on services, and employment status. After 6 to 9 months of unsuccessful job search, or after 6 weeks of employment (whichever came first), participants repeated the self-efficacy and anxiety measures, as well as questionnaires to assess their satisfaction.

Results: Participants were 28 males and 5 females whose ages ranged from 19 to 49 years. Twenty-eight percent had a high school degree, 30% a college degree and 24% went to university. Half of the participants lived independently (55%). Most were single (79%) and 9% were parents. Half of participants (55%) had no work experience or less than six months. Thirty percent had an SRS-2 global score in the mild range, 27% in the moderate range and 21% in the severe range. Adaptive scores were normal or above average for 67% of participants. Sixty percent of participants had a 2nd diagnosis, the most common of which were ADHD, depression, general anxiety disorder, unspecified mental health disorder, physical or sensory impairments. Anxiety scores were significantly higher than working population (p=0.001). Work self-efficacy score was low (63%) and negatively correlated with work situational anxiety (–0.538; p=0.001). Data collection for employment status is ongoing. Of 28 participants, 45% found competitive employment, 9% competitive employment with a partial salary subsidy, 6% a paid internship to develop job skills, 9% went back to school, 6% were still looking for a job 6 months after starting services. Sixteen participants filled up follow-up questionnaires (7 are lost to follow-up) and were satisfied with services. Those employed (12) were somewhat satisfied with their job, positive about their supervisor, but less with colleagues.

Conclusions: Participants showed strengths regarding adaptive skills, a high proportion of participants have a normal score, and regarding education, 54% have post-secondary education. Half of the participants never had a job or did not have more than 6 months of work experience, showing a need for employment support. Preliminary results indicate that participants were satisfied with services and 54% found employment. Job duration is a concern and will be investigated.

26 **200.026** Pronounced Overlap of Autistic and Schizoid Personality Trait Burden in Adolescence

M. Cook[1]*, J. N. Constantino*[1] *and Y. Zhang*[2]*, (1)Washington University School of Medicine, St. Louis, MO, (2)Washington University School of Medicine, Saint Louis, MO*

Background: Similarities in the respective clinical presentations for (a) schizoid personality disorder (PD) and (b) autism spectrum disorder (ASD) have long been recognized (Wolff & Barlow, 1979), but never formally reconciled with the question of whether they reflect overlapping developmental origins, nor whether the reciprocal nature of their respective frequencies over the life course (with ASD historically more common in childhood and schizoid PD more common in adulthood) reflects symptom continuity between the two conditions.
Objectives: This study explored the association between trait-like elements of the autistic syndrome and schizoid PD symptoms in a longitudinal study of youth with and without high-functioning autism spectrum disorder (Wagner et al., 2018).

Methods: We compared verbal males with ASD, ages 11-25 (n=53) with non-ASD psychiatric controls in the same age range (n=22) with respect to quantitative autistic trait burden using the Social Responsiveness Scale-2 (SRS-2, parent- and teacher-report) and schizoid PD trait burden using the Diagnostic Interview for Genetic Studies (DIGS, parent- and self-report, with diagnostic criterion items presented on a 4 point Likert scale for frequency). In this cohort, scores on the SRS-2 exhibited marked stability from childhood through adolescence.

Results: Both autistic traits and DSM IV schizoid PD criterion item burden were continuously distributed throughout the sample (Fig. 1), and individuals with ASD manifested a distinct pathological shift in comparison to non-ASD controls (Table 1, $t(50) = 5.6$, $p<.001$ with an effect size of 1.35); the magnitude of the between-groups difference was comparable to that for autistic trait burden. Moreover, within individuals, schizoid PD and autistic traits were strongly correlated (r =0.46, $p<.01$). When selecting a Likert-scale threshold of 2 ("often true" or higher) for schizoid PD endorsement on the DIGS, 54% of high-functioning ASD males exceeded the threshold in comparison to less than 10% of their counterparts in the non-ASD psychiatric control group (n=2). We next explored specific symptoms that contributed to similarities and differences between groups, notably distinctive of which were ASD participants' most frequently endorsed lack of close friends and tendency to choose solitary activities. 5.8% of subjects with ASD met full diagnostic criteria for schizoid PD, in comparison to 0% of the non-ASD psychiatric control group.

Conclusions: Over half of high-functioning males with ASD demonstrate unequivocal schizoid PD trait burden in adolescence. It is extremely likely that historic cohorts of adults diagnosed with schizoid PD either: a) had childhood-onset autistic syndromes; b) have been misdiagnosed; and/or c) have syndromes that were substantially contributed by autistic trait burden throughout childhood. Future studies to clarify overlap and distinctions between these two syndromes are strongly warranted, given that higher-functioning ASD syndromes are now recognized in close to 1% of all children, and that the characterizing features of both conditions are continuously distributed in the population.

27 **200.027** Selective Attention and Context Memory in Adults with ASD

P. S. Powell[1] *and A. Duarte*[2]*, (1)School of Psychology, Georgia Institute of Technology, Atlanta, GA, (2)Georgia Institute of Technology, Atlanta, GA*

Background:
Previous evidence suggests intact item memory but impaired context memory in adults with ASD. Similar findings have been observed in healthy older adults (HOA) and thought to be related to deficits in relational binding (i.e., forming an association between the item and context). However, this deficit can be overcome when attention is directed towards single item-context associations (James et al., 2016; Powell et al., 2018). While many studies used aging analogies to describe the pattern of memory performance in ASD, few have directly compared performance to HOA (Bowler, et al., 2004; 2007; Ring et al., 2016).

Objectives:

To address whether context memory performance in adults with ASD can be characterized as 'cognitively old', and whether it can be improved when attention is directed towards single item-context associations.

Methods:

Participants were 22 young adults (ages 18–35), 18 HOA (ages 60–80), and 26 adults with ASD, ages 20–58. Participants completed an experimental task designed to assess item memory and context memory. During the study phase, participants were shown a centrally-presented object in the presence of two contextual features: a color and a scene positioned to right and left of object. For each trial, participants directed their attention to the object's relationship with one of the two contextual features (Target Context) while ignoring the other (Distractor Context). EEG was recorded throughout the experiment.

Results:

Memory for the centrally-presented object (item memory) indicated similar performance across diagnostic groups (Younger: M = .73; Older: M = .71; ASD: M = .62), $F(1,49) = 1.71$, p = .20, η_p^2 = .07. Next, the proportion of correctly recognized Target and Distractor Contexts was examined using a 2 (Target vs. Distractor) by 3 (Diagnostic Group: ASD vs. Younger vs. Older) Repeated Measures ANOVA. This analysis demonstrated a main effect of context indicating greater memory for the target context relative to the distractor context (M = .66, SD = .11; M = .52, SD = .04, respectively), $F(1,63) = 92.66$, $p < .001$, η_p^2 = .65. However this main effect was qualified by a significant context by diagnostic group interaction, $F(2,63) = 8.56$, p = .001, η_p^2 = .26. Post-hoc comparisons indicated target context memory was significantly greater in younger adults (M = .74, SD = .08) relative to HOA (M = .63, SD = .06) and adults with ASD (M = .59, SD = .12). There was no difference in performance between adults with ASD and HOA.

Conclusions:

The current findings suggest that context memory in adults with ASD can be improved when attention is directed to single item-context associations. However, the level of context memory performance in adults with ASD was more comparable to the level of performance seen in HOA than younger adults, suggesting a 'cognitively old' pattern of context memory performance. Given that the majority of current sample of adults with ASD were less than 45 years old, these findings may have important implications for the specific cognitive abilities that may be more disrupted in adults with ASD as they age.

28 **200.028** A Participatory Exploration of Writing Skills and Predictors of Writing Quality Among Autistic and Non-Autistic College Students

K. Gillespie-Lynch[1]*, E. Hotez*[2]*, D. Bublitz*[3]*, A. Riccio*[4]*, D. DeNigris*[5]*, M. C. Zajic*[6]*, K. Luca*[7]*, B. Kofner*[7] *and N. Gaggi*[8]*, (1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)City University of New York, Hunter College, New York, NY, (3)Dr., NY, NY, (4)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (5)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (6)University of California at Davis MIND Institute, Davis, CA, (7)CUNY, NY, NY, (8)College of Staten Island, Staten Island, NY*

Background: Although essential for success in college, the writing skills of autistic college students have received limited empirical attention (Gerstle & Walsh, 2011; Jackson et al., 2018). Autistic people often exhibit writing difficulties (Brown et al., 2014; Zajic et al., 2018). Difficulties with Theory of Mind (ToM) and/or global coherence may contribute to narrative challenges in autism (Brown & Klein, 2011; Joliffe & Baron-Cohen, 2001). However, some autistic adults report communicating *more* effectively through writing than speaking (Davidson & Smith, 2009) and autistic people with developed language skills may not struggle with ToM (Happé, 1995). Therefore, autistic college students may not experience specific challenges writing. As writing demands change throughout the lifespan (Bazerman et al., 2018), more information about the writing abilities of autistic college students is critical.

Objectives: To compare the writing skills of autistic and non-autistic college students and to examine predictors of writing quality.

Methods: Autistic (n = 26; 92.6% male; 64% White; Mean age = 21.3) and non-autistic college students (n = 24; 43.5% male; 45% White; Mean age = 20.5) completed a measure of ToM (RMIE; Baron-Cohen, 2001), a global integration task (Joliffe & Baron-Cohen, 2011), a personal essay (wherein they were asked to share something they found meaningful by highlighting what it meant to them and whether or not it would mean the same thing to others), and a short story. After realizing that our initial hypotheses/coding lacked autistic perspectives, we asked two autistic college students to develop their own hypotheses and coding schemes. One neurotypical and one autistic coding pair developed coding schemes and obtained reliability. The neurotypical coding scheme included global coherence, ToM, and non-literal language. Autistic coders coded for creativity, readability, specificity, repetitiveness, emotional dullness, and point of view. We used paper.rater.com to assess length, errors, and quality (AutoGrader).

Results: Autistic students (20%) less frequently included multiple perspectives in their essays than non-autistic students (67%; p = .001). Their essays trended toward lacking global coherence (autistic 20%; non-autistic 0%, p = .051) and being more creative (15% autistic; 0% non-autistic; insufficient instances for chi-square analysis). Autistic students' essays exhibited *fewer* simple sentences and *heightened* writing quality. Autistic students used fewer simple sentences and more complex vocabulary in their stories ($ps < .02$). No qualitative group differences in fiction were observed. A linear regression revealed that autism classification (r = .55) and RMIE (r = .53, $ps < .004$), but not age or gender, were positively

associated with writing quality. Global integration was not included in the regression due to collinearity with RMIE, $r(38) = .04$, $p = .01$ but was *not* correlated with writing quality.

Conclusions: Autistic students exhibited subtle difficulties using ToM in their personal essays (wherein attention to multiple perspectives was prompted) but not in open-ended fictional writing. Though demonstrating variability, findings suggest that autistic college students leverage narrative skills to help them succeed in college and understand others. Future participatory explorations of the writing of autistic college students should examine institutional factors that contribute to writing development longitudinally.

29 **200.029** A Thematic Analysis of First-Hand Reports of Face Recognition and Eye Contact in Adults with and without Autism Spectrum Disorder

K. B. Parkington *and R. J. Itier, Psychology, University of Waterloo, Waterloo, ON, Canada*

Background: It is well-established that many individuals with autism spectrum disorder (ASD) exhibit difficulties with maintaining and integrating eye contact during social overtures. Anecdotal reports have alluded to experiences of sensory or emotional overload when individuals with ASD engage in mutual eye contact, as well as a general unawareness of why eye contact is "necessary". However, it remains unclear what thematic relationships are present amongst a number of individuals on the spectrum, as well as what factors and motivations underlie this socially salient behaviour. Empirical theories also propose that reduced eye contact may lead to cascading effects in social cognition, including face recognition difficulties, a concept yet to be addressed in qualitative reports.

Objectives: We sought to understand how adults with and without ASD experience eye contact and situations involving face recognition to clarify the motivations and reasons guiding their social behaviours.

Methods: A thematic analysis was conducted on semi-structured interviews collected in a sample of high-functioning adults with ASD and age-, gender-, and IQ-matched neurotypical adults in relation to their feelings, beliefs, and experiences with face recognition and the engagement of eye contact.

Results: Whilst adults with ASD were more likely than neurotypical adults to report difficulties with face recognition, a relationship between attention to another person's eyes and face recognition was not reported by either group. Most adults with ASD reported they were aware of social conventions surrounding eye contact, indicating an awareness that it helps establish connection, rapport, and social attention with another person. Many also indicated they can engage in eye contact when required by social demands but if offered a choice would prefer to allow their eyes to wander or look away from the person completely. Several adults with ASD also discussed using strategies which mimic eye contact to an observer (e.g., looking at the forehead, nasion, or nose). A few informants also reported that attending to the eyes results in perceptual or sensory overload and "too much information", leading to tendencies to look to less visually distracting areas. Adults with ASD also reported difficulties in maintaining eye contact when in a pre-existing emotional state, especially increased states of anxiety or depression, and eye contact itself was also deemed to be emotionally and/or physiologically overwhelming, thereby making regulation more difficult. Finally, whilst both groups reported reduced eye contact when thinking or trying to collect their thoughts, adults with ASD exclusively reported increased cognitive load during interactions, particularly in relation to monitoring socially anxious thoughts and gaze duration. These findings will also be discussed in relation to gender differences and how reports coincide with quantitative measures of face recognition and attention to the eyes.

Conclusions: These first-hand reports confirm that whilst adults with ASD are able to engage in mutual eye contact to a degree, many experience perceptual, emotional, and/or cognitive overload, making continuous eye contact difficult or uncomfortable. These findings have important implications for understanding the motivations sub-serving gaze behaviours in ASD, and the need for individualized interventions targeted to the type of overload experienced.

Poster Session
201 - Affective Neuroscience
5:30 PM - 7:00 PM - Room: 710

30 **201.030** Behavioral and EEG Abnormalities during Cognitive Control and Visual Perception in Autism Spectrum Disorder (ASD)

A. Lassalle*, Psychology (Brain & Cognition), University of Amsterdam, Amsterdam, Netherlands*

Background: People with Autism Spectrum Disorder (ASD) are hypothesized to show atypical connectivity. However, the majority of studies testing this hypothesis used MRI, a technique with limited temporal resolution.

Objectives: Here we use EEG to investigate the temporal dynamics and the network properties of the brain connections associated with behavioral differences in ASD during rest, visual perception of gratings of varying spatial frequency, and cognitive control (i.e., Simon Task).

Methods: Young adults with and without ASD (N=17 in each group) matched on age, gender, and estimated intelligence quotient (IQ) were recruited. We measured their behavior and their EEG during rest, a low-level visual perception task, and a cognitive control task. Offline, we computed EEG power and inter-site phase clustering (ISPC; a measure of connectivity) in various frequency bands, as well as visual Event Related Potentials (ERPs).

Results: During rest, there were no ASD vs. controls differences in EEG power, suggesting typical oscillation at baseline. During visual processing, we found a decreased broadband EEG power in ASD vs. controls pre-baseline normalization that we interpret as an indication of higher efficiency in visual processing in ASD. We also found decreased P2 ERP amplitude in ASD vs. controls during visual processing, which may suggest higher ability to ignore irrelevant aspects of stimuli. This ability to ignore irrelevant aspects of stimuli was most apparent with the behavioral results of the Simon task (i.e., reverse Simon effect in controls but not in ASD participants) and is consistent with an increased fluid intelligence in ASD.

Conclusions: Our results of (1) typical EEG at rest, (2) decreased interference to irrelevant stimuli during the Simon task, and (3) enhanced efficiency of visual processing in ASD vs. controls demonstrate areas of strength in the cognitive profile of autistic young adults.

31 **201.031** Comfortable, Valid and Reliable? Measuring Stress in Children with ASD Using Select Consumer-Grade Heart Rate Trackers

H. J. Nuske[1], *Y. Kushleyeva*[2], *D. Forsyth*[2], *J. W. Pennington*[2], *A. J. Masino*[2], *E. Finkel*[3], *A. Bhattacharya*[4], *D. S. Mandell*[1], *C. P. Bonafide*[5] *and J. D. Herrington*[6], *(1)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (2)Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Department of Psychology, University of Pennsylvania, Philadelphia, PA, (4)PolicyLab and the Eating Disorder Assessment and Treatment Program, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Center for Pediatric Clinical Effectiveness, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: New wearable monitoring devices have the potential to revolutionize psychophysiology research among people with ASD by bringing it to the settings that matter – out of the laboratory and into schools and homes. However, due to sensory sensitivities, people with ASD may not be comfortable wearing such devices. In addition, formal testing of the reliability and validity of such devices among people with ASD is limited. Objectives: This study tested whether commercially-available heart rate trackers (1) can be comfortably worn by children with ASD, and (2) validly and reliably measure stress in children with ASD.

Methods: 55 children, 32 with ASD and 23 without ASD, 8-12 years old were fitted with four heart rate trackers, including one chest-strap (Polar H7), two wrist-bands (Mio Fuse and Pulse On), and one set of headphones (Jabra). They participated in a two-hour battery that included a rest task (watching a relaxing video) and low-level stress tasks taken from the Laboratory Temperament Assessment Battery, including the transparent box task. Heart rate (beats per minute; BPM) and heart rate variability (R-R interval) data were recorded simultaneously from each of the devices with custom software. Researchers administered the Comfort Rating Scales to children at the end of the session; children rated the devices on eight dimensions: 1) Emotion (*I feel tense or on edge because I am wearing the device*); 2) Attachment (*I can feel the device on my body*); 3) Harm (*the device is causing me some harm*); 4) Perceived change (*I feel strange wearing the device*); 5) Movement (*the device affects the way I move*); 6) Anxiety (*I do not feel secure wearing the device*); 7) Sensory sensitivity (*the device feels annoying on my skin*); 8) Attention on sensation (*I cannot stop thinking about the feeling of the device on my skin*). Validity of stress measurement was analyzed using BPM and R-R interval data in 2 groups (ASD, non-ASD) 2 tasks (rest, stress) repeated measures ANOVAs.

Results: *Comfortability.* As shown in Table 1, 85% of children with ASD kept the Mio Fuse wrist-band and Polar H7 chest-strap on during the entire session (fewer children kept the other devices on). Although the Polar H7 chest-strap was less comfortable for children with ASD than for children without ASD with regards to the Emotion and Movement dimensions, absolute scores show that, on average, all children found the devices comfortable (see Figure 1). *Validity.* In the stress relative to rest condition, heart rate went up for the Polar H7 chest-strap, $F(1,41)=56.27$, $p<.001$, $\eta p^2=.58$, and Mio Fuse wrist-band, $F(1,40)=13.70$, $p=.001$, $\eta p^2=.26$, respectively, and R-R interval (ms) went down for the Polar H7 chest-strap, $F(1,41)=56.27$, $p<.001$, $\eta p^2=.58$, and Mio Fuse wrist-band, $F(1,40)=21.17$, $p<.001$, $\eta p^2=.35$, respectively. *Reliability.* Presentation of results will include technical reliability data (spike rate and sampling fidelity).

Conclusions: Findings show that select heart rate devices may be used for measuring stress in children with ASD. Results from this study may inform methodologies used in future studies to measure physiological stress in children with autism in community settings.

32 **201.032** Emotional Facial Expressions Evoke Regionally-Specific Activation in the Amygdala in Children, Adolescents and Adults with Autism Spectrum Disorder Relative to Typically-Developing Individuals

D. Seguin[1], *J. Chen*[1], *R. Nicolson*[1,2], *J. Martinez-Trujillo*[1] *and E. G. Duerden*[3], *(1)Western University, London, ON, Canada, (2)Children's Hospital London Health Sciences Centre, London, ON, Canada, (3)Education, Western University, London, ON, Canada*

Background: Direct eye gaze is essential for the identification of emotional expressions. Averted gaze is a common behavioural phenotype in children with autism spectrum disorder (ASD), which is thought to underlie social communication impairments seen in this population. While averted gaze is increasingly included in early diagnostic assessments for ASD, the neural mechanisms are poorly understood. Previous neuroimaging studies have reported conflicting reports on the neural activation and behavioural responses during viewing of emotional face stimuli in individuals with ASD, with some studies reporting hyperactivation in the amygdala and fusiform gyri, key regions for emotional face processing, while others have reported hypoactivation. Findings may reflect differences in saliency cues directed towards the eye region when viewing emotional face stimuli during the experimental tasks.
Objectives: Using meta-analytic methods, to determine whether individuals with ASD demonstrate differential activation in brain regions involved in processing emotional face stimuli, compared to typically developing (TD) individuals. Further, we aim to examine whether task differences (constrained or fixated gaze) affects regional activation in the brain, particularly in the amygdala.

Methods: A comprehensive literature search of electronic databases was conducted for peer-reviewed studies which included comparisons of functional magnetic resonance imaging (fMRI) data acquired during an emotional face viewing task between individuals with ASD and typically developing controls. BrainMap GingerALE v2.3 was used to conduct an Activation Likelihood Estimate (ALE) meta-analysis of all studies found which met the inclusion criteria. Data were corrected for multiple comparisons using the false discovery rate (FDR, $p<0.05$).

Results: A total of 22 studies were identified, encompassing data from 418 individuals diagnosed with ASD, and 476 TD participants (ages ranging from 8-44 years), which served as a comparison group. A further measure of constrained or fixated eye gaze to the eye region of the stimuli was identified in 8 of these studies (comprised of 184 individuals with ASD and 219 TD individuals), which were included in sub-analyses examining the likelihood of activation in the brain in response to constrained gaze during the emotional face processing tasks. Analyses of all studies, regardless of gaze constraints, confirmed significant bilateral amygdala activation in both typically developing (right: $p=0.004$; left: $p=0.004$) and ASD individuals (right: $p=0.003$; left: $p=0.003$). The fusiform gyrus was activated only in TD participants only ($p=0.003$). The analyses of the constrained eye gaze studies revealed that only ASD participants had increased activation of the left amygdala in compared to TD controls ($p=.003$).

Conclusions: ASD and TD participants employ different networks when processing emotional face stimuli. Findings from the constrained gaze analyses, suggest individuals with ASD are experiencing increased arousal reflected in an increased likelihood of evoking activation in the left amygdala when viewing the eye region of emotional stimuli. Desire to avoid this negative biological response to emotional stimuli, and eye regions specifically, may underlie atypical gaze patterns and emotional face processing in individuals with ASD.

33 **201.033** Mindfulness Training-Induced Increases in Middle Cingulate Cortex Activity during Self-Reflection Predicts Depression-Reduction in Adults with Autism Spectrum Disorder

B. A. Pagni[1], *M. Walsh*[2], *E. Foldes*[2], *A. Sebren*[2], *L. C. Baxter*[3], *M. Dixon*[2], *C. Riecken*[4], *C. Haynes*[2], *A. Macomber*[2], *A. Clark*[2], *C. Webb*[2], *M. Catchings*[2], *J.*

Alvar[2] and B. B. Braden[2], (1)College of Heath Solutions, Arizona State University, Tempe, AZ, (2)College of Health Solutions, Arizona State University, Tempe, AZ, (3)Radiology, Barrow Neurological Institute, Phoenix, AZ, (4)University of Missouri, Columbia, MO

Background: Adults with autism spectrum disorder (ASD) experience high rates of depression and anxiety. There is some evidence that Mindfulness-Based Stress Reduction (MBSR) is effective in reducing depression and anxiety in adults with ASD, however the neural mechanisms and benefit above and beyond support/education groups are unknown. Functional MRI (fMRI) research shows adults with ASD do not activate the ventral medial prefrontal cortex (vmPFC) and middle cingulate cortex (MCC) during self-reflection as seen in neurotypical (NT) adults. Mindfulness training regulates self-reflection neural activation in NT adults, making this a likely mediator of symptom-reducing effects in adults with ASD. Objectives: In a pilot study, we investigated whether adults with ASD who received MBSR training increased the blood-oxygen-level dependent (BOLD) response in regions activated during self-reflection, compared to a support/education control group, and if the BOLD signal change correlated with changes in self-reported depression and anxiety.

Methods: Twenty-eight adults (nine women; mean age=31.8±12.9, range=18-64; mean IQ=106±18.5, range=70-139) with ASD were randomly assigned to an 8-week MBSR group (n=15) or a support/education control group (n=13). All participants self-reported an ASD diagnosis and met ASD criteria on the ADOS-2. The MBSR training was adapted by removing metaphorical language similar to Spek et al. (2013), and was co-instructed by an experienced MBSR instructor and ASD clinician. Participants met for two-hours once/week for eight weeks with homework. The novel control group met for the same amount of time with a cognitive neuroscience instructor to control for social interaction/support. Control participants were given minimal education on relaxation techniques from the National Center for Complementary and Integrative Health and homework. Pre- and post-intervention fMRI scans were collected for the self-reflection task where participants: (1) reflected on whether or not the word displayed was a trait they possessed (self-condition), and (2) made a judgement about the positive or negative valence of words (word-condition). Self-reported symptom ratings were assessed via the Beck Depression Inventory-2 and the State-Trait Anxiety Inventory. Within group comparisons were performed with paired t-tests and correlations with Pearson product-moment.

Results: The MBSR group demonstrated significant depression reduction with a moderately-large effect size ($t(14)=3.31$, $p=0.005$, $d=0.66$; Fig. 1a). The control group's depression reduction approached significance with a moderately-small effect size ($t(12)=1.82$, $p=0.09$, $d=0.40$; Fig. 1a). Neither group significantly reduced anxiety symptoms (Fig. 1b). The MBSR group demonstrated increased activation in MCC ($p=0.018$, small-volume family-wise error corrected; Fig. 2a), but not vmPFC, in the Self>Word contrast after training; the control group demonstrated no changes. Change in MCC activation was negatively correlated with depressive symptom change in the MBSR group ($r(11)=-0.49$, $p=0.04$ one-tailed; Fig. 2b).

Conclusions: In a pilot study, we demonstrated that MBSR is effective for reducing depression in adults with ASD, and the neural mechanism may be increased MCC activation during self-reflection. Additionally, our novel support/education group shows promise for modest depression-reduction, which is an important consideration for individuals or communities with limited access to or funding for MBSR training. A larger clinical trial is warranted to fully understand the efficacy and neural mechanisms of each behavioral intervention.

34 **201.034** Neurobiological Markers of Vocal Emotion Recognition in the Broader Autism Phenotype

***V. Yap**[1], A. Connelly[2], I. E. Scheffer[2,3,4] and S. J. Wilson[1,2], (1)Melbourne School of Psychological Sciences, The University of Melbourne, Melbourne, VIC, Australia, (2)Florey Institute of Neuroscience and Mental Health, Melbourne, VIC, Australia, (3)Department of Medicine, The University of Melbourne, Austin Health, Melbourne, VIC, Australia, (4)Department of Paediatrics, The University of Melbourne, The Royal Children's Hospital Melbourne, Melbourne, VIC, Australia*

Background: Relatives of individuals with Autism Spectrum Disorder (ASD) demonstrate atypical brain activation in regions of the "social brain" when judging emotional states in the face and eyes. These findings are consistent with an ASD profile and suggest the presence of neurobiological markers of the Broader Autism Phenotype (BAP), or endophenotypes of ASD, for emotion recognition. Neuroimaging studies have not examined whether the BAP in relatives is also associated with atypical brain activation for the recognition of emotional voices, although there is evidence for this in individuals with ASD.

Objectives: We aimed to examine the neural correlates of vocal emotion recognition in relatives of individuals with ASD, specifically using non-linguistic emotional vocalizations known as vocal affect bursts (e.g., laughter, cries, screams).

Methods: We assessed 13 adult family members of individuals with ASD and 13 adult controls without a family history of ASD (matched on age and IQ). The family group consisted of first-degree (n = 11) and second-degree (n = 2) relatives from seven different families. Prior to recruitment, all family members were determined to have clinical markers of the BAP on extensive cognitive and behavioural testing, and all controls were screened for BAP traits on a self-report measure. The block-design fMRI task consisted of (i) "emotion" blocks, in which participants identified basic emotions in vocal affect bursts, and (ii) "gender" (baseline) blocks, in which they identified gender (male/female) in non-linguistic neutral vocalizations. We used whole-brain, fixed effects analyses to determine brain activation in each group ("emotion > gender" contrast) and to compare activation between groups at a cluster-corrected threshold.

Results: The family group and controls were able to classify vocal affect bursts at ceiling levels, suggesting brain activation reliably related to correct task performance. Both groups largely activated similar networks (e.g., social brain, mirror neuron system and memory structures; salience, cognitive control, motor and visual networks). However, while controls demonstrated bilateral activation in the superior temporal sulcus (STS) and adjacent middle temporal gyrus (MTG), activation in these regions were left-lateralised in the family group. Between-groups analyses also revealed that the family group had significantly higher activation than controls in the left lateral occipital cortex, whereas no regions showed significantly lower activation in the family group.

Conclusions: Our findings suggest that the family group used neural compensatory mechanisms to successfully classify vocal affect bursts. In particular, they appeared to engage in more effortful processing of vocal affect bursts in left rather than right temporal voice areas (e.g., STS/MTG), which could have contributed to increased left occipital activation. This is consistent with previous research indicating that temporal voice areas are connected to the ipsilateral occipital cortex and that occipital activity is modulated by attention to auditory stimuli. Increased left occipital activation may also indicate more cross-modal processing (e.g., visual imagery) to perform the task. Overall, our findings suggest a neurobiological marker of the BAP for vocal emotion recognition.

35 **201.035** Symptoms of Depression but Not Anxiety Modulate Resting State Activity in Children with ASD

***M. L. Airey**, L. Blaskey, E. S. Kuschner, H. L. Green, M. DiPiero, M. Ku, M. Kim, T. P. Roberts and J. C. Edgar, Children's Hospital of Philadelphia,*

Philadelphia, PA

Background:
Alterations to resting-state alpha activity have been identified in a number of neuropsychiatric and neurodevelopmental conditions. Previous work from our laboratory showed age-related increases in peak alpha frequency (PAF) in typically developing children (TDC) but not in children with autism spectrum disorder (ASD). Lack of change in the ASD sample was attributable to early maturation of PAF, such that younger (6 to 9-year-old) children with ASD had significantly higher PAF values than TDC. In contrast, older children with ASD had similar or slightly lower PAF values than TDC. Given the literature on alpha activity alterations in individuals with depression and anxiety, as well as high rates of comorbid anxiety/depression in ASD, the present study sought to examine effects of co-occurring anxiety and depression symptoms on resting-state alpha activity in children with ASD.

Objectives:

To explore the association between PAF and clinical symptoms of anxiety/depression in children with ASD.

Methods:

Magnetoencephalography (MEG) resting-state eyes-closed data were obtained from 89 male children with ASD, ages 6 to 17 (mean age = 10.03 +/- 2.42). Using BESA Research 6.1, a source model with 15 regional sources projected the raw MEG surface data into brain source space and a Fast Fourier Transform was applied to artifact-free 3.41 second epochs of continuous data at each regional source. From the 15 average power spectrum, PAF was identified in each participant from the source (most often the midline parietal source) showing the largest amplitude alpha activity (8-12Hz). Clinical measures of interest included parent-rated anxiety and depression symptoms on the Child Behavior Checklist (CBCL) and indices of behavioral regulation and emotional control by parent report on the Behavior Rating Inventory of Executive Function (BRIEF).

Results:

Correlations indicated that higher levels of depression were associated with lower PAF ($p = 0.05$, $r = -0.03$). Given known associations between age and PAF, follow-up analyses examined findings in younger (6-9 years) versus older (10-17 years) children. Results indicated a significant negative association between depression symptoms and PAF in younger ($p = 0.02$, $r^2 = 0.10$) but not older ASD children ($p = 0.83$, $r^2 = 0.002$). No associations were observed between PAF and anxiety symptoms ($r^2 = 0.002$).

Conclusions:

Increased symptoms of depression were associated with lower PAF values in younger children with ASD, whereas no associations were observed between PAF and anxiety measures. These findings therefore suggest that co-occurring depression symptoms modulate PAF in ASD, altering the anticipated ASD pattern. Further work with larger samples is needed to better understand the effect of mood symptoms on resting-state alpha activity in ASD, with particular focus on younger children, who may be most susceptible to altered alpha activity in the context of symptoms of depression.

36 **201.036** Young Adults' Autistic Behaviors Predict N170 Responses to Emotional Faces

***M. Blottner**, S. C. Taylor, J. Burk and C. L. Dickter, College of William and Mary, Williamsburg, VA*

Background:
Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by deficits in communication and social interaction. ASD individuals show impairments in emotion identification, especially for negative and complex emotions. This deficit may be related to neural differences in the processing of faces; previous psychophysiological research suggests that autistic individuals show differences in activity in brain areas necessary for facial recognition than non-autistic individuals. In particular, the N170 event-related potential (ERP) has been established to be sensitive to the neural processing of faces. Thus, examining N170 activity during face processing may help reveal the neural correlates of early emotion identification in autism.

Objectives: The purpose of the current study was to test whether the neural processing of emotional facial expressions differs as a function of levels of autistic traits and differs based on task type in a neurotypical adult population. Because ASD is a spectrum condition, using non-clinical samples of individuals on the broader autism phenotype (BAP) can help us understand emotion processing related to ASD. Studying low and high BAP individuals allows us to isolate the effects of autistic traits on emotional processing between groups that are well-matched, limiting confounding variables between groups. The current study uses both full-face and eye region stimuli to control for known behavioral scanning differences and to isolate the resulting impact on neural activity.

Methods:

Neurotypical participants (n=34) completed an emotion identification task while EEG data were recorded. For each trial, a face depicting an emotion (happy, angry, fear, surprise) or a neutral expression was presented for 1000 ms; an inter-stimulus interval of 500 ms was used between trials. In half of the trials, participants indicated if the emotion of the face matched that of the face presented before it (matching task). In the other trials, participants indicated if the emotion of the face was positive or negative (valence task). Each participant completed the Broad Autism Phenotype Questionnaire (BAPQ) to measure their level of autistic traits.

Results:

A 5 (Emotion: Angry, Fear, Happy, Neutral, Surprise) x 2 (Task: Valence, Matching) x 2 (BAPQ: Low, High) mixed model Analyses of Variance (ANOVA) was conducted. For the matching trials, there were no significant effects. For the valence task, however, there was a significant Emotion x BAPQ interaction, $F(4,88) = 3.83$, $p = .025$. Simple main effects analyses revealed that for the fear trials, low BAPQ participants demonstrated a larger amplitude N170 than high BAPQ participants, $t = -2.68$, $p = .014$. Furthermore, correlational analyses revealed that BAPQ was significantly correlated with N170 amplitude for angry faces, $r = .37$, $p = .033$.

Conclusions:

These results provide a better understanding of neural activity during emotion processing for those on the BAP and add to work investigating the neural underpinnings of emotion processing deficits for ASD individuals. By studying social processing within the wider context of the BAP, we are better able to evaluate specific autism-associated behaviors in isolation of other clinical features as well as include a broader community of persons with autistic traits.

37 **201.037** Young Children with Autism Spectrum Disorder Exhibit Shorter Average Look Duration to Social As Compared to Nonsocial Stimuli

S. Major[1], *D. Y. Isaev*[2], *J. N. Buttinger*[2,3], *T. Calnan*[2], *C. Manis*[2], *J. N. Grapel*[4], *G. Sapiro*[5], *M. Murias*[1] *and G. Dawson*[6], *(1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences Duke University School of Medicine, Duke Center for Autism and Brain Development, Durham, NC, (4)Neurophysiology Laboratory, Duke Center for Autism and Brain Development, Durham, NC, (5)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: When viewing complex dynamic stimuli, children with autism spectrum disorder (ASD) spend a lower proportion of time looking at the social as compared to the nonsocial elements (reduced *social attention*) of those stimuli. In this analysis, we evaluate a different measure related to social attention, namely, the *average look duration* to a social vs nonsocial stimulus. We were also interested in whether individual differences in average look duration to a social stimulus are correlated with social communication abilities and autism symptom severity.
Objectives: Our objectives were to 1) determine the average look duration of children with ASD to social versus nonsocial elements of a complex dynamic stimulus, and 2) examine the relationships between two measures of social attention, namely, the proportion of time spent looking at social elements and the average look duration to social elements, and measures of social communication abilities and autism symptoms. We hypothesized that children with ASD would exhibit shorter average look duration to social as compared to nonsocial elements, and that shorter look duration to social elements would be associated with lower social communication abilities and more severe autism symptoms.

Methods: One hundred seventy-six participants 2-8 years meeting criteria for ASD based on the Autism Diagnostic Observation Schedule-2 (ADOS) and Autism Diagnostic Interview-R, participated in a clinical trial. An eye-tracking task, administered at baseline, consisted of a 3-minute video that included an episode involving a social bid by an actress (social condition) and an episode when toys were activated (nonsocial condition). Sixteen subjects were excluded due to non-compliance and calibration failures (n=160, M age=65.3 months, M FSIQ=70.6). To measure average look duration, we divided total viewing time by the total number of looks to both stimulus conditions. We also measured the proportion of time spent looking at the actor and her face during the social condition. Correlations with Vineland Adaptive Behavior Scales-3, Pervasive Developmental Disorder Behavior Inventory (PDDB-I), and ADOS severity score were examined using multivariable linear regression controlling for age and FSIQ with α=0.05.

Results: As predicted, average look duration during the social condition was significantly shorter than during the nonsocial condition (M=3.11 (±1.10) and 3.89 (±1.63) respectively, p<0.001). Lower proportion of time spent looking at the actor was correlated with more severe symptoms, based on ADOS severity score (p=0.04). Shorter look duration during the social condition was associated with more severe symptoms (PDDB-I Receptive/Expressive Social Communication Abilities (p=0.004), PDDB-I Social Approach Behaviors (p= 0.03), and PDDB-I Autism Composite (p=0.05)). Look duration during the nonsocial condition was not correlated with symptom severity.

Conclusions: Young children with ASD exhibit shorter average look durations when viewing social stimuli, as compared to nonsocial stimuli. Furthermore, longer average look durations to social, but not nonsocial, stimuli were associated with reduced autism symptoms. The ability to look at a complex social stimulus for longer periods may reflect more advanced self-regulatory skills and lead to enhanced engagement with and comprehension of complex, dynamic social stimuli.

Poster Session
202 - Clinical Genetics
5:30 PM - 7:00 PM - Room: 710

38 **202.038** A Diagnostic Journey in Neurodevelopmental Disorders: Toward Improving Comprehensive Care for Children with Neurodevelopmental Disorders and Neurogenetic Conditions.

R. R. Wilson[1], ***C. M. Stephens***[2], *K. V. Cassidy*[2], *A. Besterman*[2], *J. A. Martinez-Agosto*[3] *and S. Jeste*[4], *(1)UCLA Medical Center, Los Angeles, CA, (2)UCLA Center for Autism Research & Treatment, Los Angeles, CA, (3)Departments of Human Genetics, Pediatrics and Psychiatry, University of California, Los Angeles, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA*

Background: Established medical practice parameters for genetic testing in Neurodevelopmental Disorders (NDDs) has led to the identification of numerous genetic variations associated with these conditions (Schaefer et al, 2013; Duffourd et al, 2016; Sawyer et al, 2016). However, families continue to face barriers in access of care and diagnostic evaluation (Basel & McCarrier, 2016). In addition, our ability to identify genetic etiologies of NDDs has far outpaced our ability to provide timely medical care. Families of patients with NDDs are often left to digest complex medical terminology and explore resources that may best guide them in the care of their child.
Objectives: Our team has established the Care and Research in Neurogenetics (CARING) Clinic to provide comprehensive multidisciplinary care to patients with a NDD and known genetic etiology. We have utilized a diagnostic journey interview (DJI) to identify the major barriers in access of care and gaps in subsequent medical support following a genetic diagnosis. This study highlights the major results from our collected data.

Methods: The medical team consisting of neurologists, geneticists, and psychiatrists developed the DJI based on clinical experience and literature review. After creation of the DJI, trained staff conducted the interview with families by phone. A total of 25 families completed the DJI. The interview consists of questions regarding initial developmental concerns for the child, time from initial concern to first clinical diagnosis and to genetic testing, and medical counseling and access to services after clinical and genetic diagnoses.

Results: Numerous themes emerged from the data. Greater than 70% of families had developmental concerns for their child in the first year of life. Greater than 70% of families noted there was no availability of specialized medical evaluation in their geographic area. 57% of families noted a considerable wait time to see a geneticist. If genetic testing was obtained before referral to specialist, 80% of families reported minimal genetic counseling when results were given. Families noted that the most useful and informative resources were provided by the specializing health care provider (86%) and patient advocacy groups (57%). Qualitatively, primary care providers did not always address developmental concerns by referring to specialized practitioners, and although there was initial “fear and anxiety” in awaiting the results of the genetic testing, ultimately having the results was worth it.

Conclusions: The DJI highlights several key themes in improving medical care for patients with NDDs and their families. Moving forward, our clinic will utilize these results to share with community providers regarding the process of obtaining genetic testing and providing subsequent counseling. In addition, it is imperative as we identify known genetic disorders associated with NDDs that we begin to identify treatments that target core symptoms of the disorder. Lastly, as indicated by this interview practitioners should aid in building family networks around these genetic disorders to help support these families.

39 **202.039** Bridging the Gap: Access to Genetic Testing in a Community Sample of Individuals with Autism Spectrum Disorder

A. Rouhandeh[1], *C. Honsberger*[2], *M. Mulhern*[1], *N. Shanok*[2], *N. Huda*[2], *E. Brooker Lozott*[2], *M. Sotelo*[2], *J. Buxbaum*[3], *A. Kolevzon*[1], *S. De Rubeis*[4], *J. Foss-Feig*[1] *and P. M. Siper*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Els for Autism Foundation, Jupiter, FL, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: While genetic testing is recommended by the American College of Medical Genetics for individuals with autism spectrum disorder (ASD), access to testing and physician referrals remain limited. Testing for Fragile X syndrome and high-resolution chromosomal microarray are the first-tier genetic tests for individuals with ASD; however, the extent to which they are pursued varies widely. Recently, a medical-center based autism research center, which carries out comprehensive genetic and clinical evaluations, joined with a nonprofit organization, comprising two public charter schools and a foundation providing recreational, therapeutic, and adult services for several hundred individuals with ASD per year, in order to integrate research into a community setting. The joint institute provides genetic testing, facilitated by the research group, to individuals within the school and foundation community.

Objectives: To characterize and assess the likelihood of receiving recommended genetic testing in a community sample of individuals with ASD.

Methods: Between August and November 2018, 45 families were recruited; 15 were enrolled by November 2018, with the remainder expected to participate by March 2019. The 45 screened participants with ASD (17.78% female) ranged in age from 2 to 32 years and all carried Individualized Education Plan (IEP) classifications of ASD and/or a documented diagnosis from medical records. Results from previous genetic testing were obtained, and testing was ordered for those who had not had recommended testing. Saliva samples are collected at the local center, and DNA extraction and testing is facilitated by the research institute. Phenotyping data is being collected through parent report.

Results: Of the participants screened (n=45), 22% had previous genetic testing confirmed by reports. The average year of ASD diagnosis for those with previous genetic testing (n=10) was 2009, while that of the total population was 2008. Average age at diagnosis for those with past testing was 29 months and 36 months for the total population. In our screened sample, 17.78% of individuals were characterized as nonverbal (by parent report), and 4 of those 8 individuals received genetic testing. Of 10 individuals with past testing, 20.0% percent had an autism-related finding (Fragile X syndrome (n=1); STXBP1-associated epileptic encephalopathy (n=1)). Fragile X testing, chromosomal microarray and research whole-exome sequencing results are pending for those whose testing is being conducted through this study.

Conclusions: Preliminary results suggest that genetic testing and referrals in the community remain limited, and that neither year of diagnosis nor age at diagnosis significantly increases the likelihood of genetic testing. An important next step will be to examine additional phenotypes influencing referrals for genetic testing, including IQ, adaptive behavior, and medical and psychiatric comorbidity, as well as source of diagnosis. Future directions include identifying additional barriers to genetic testing and increasing access and ease in community settings where the majority of individuals with ASD are served.

40 **202.040** Clinical Phenotype of De Novo Mutations in CHD2

E. Kurtz-Nelson[1], *S. Trinh*[1], *A. S. Wallace*[1], *E. E. Eichler*[2] *and R. Bernier*[1], *(1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)Department of Genome Science, University of Washington, Seattle, WA*

Background: *De novo* mutations in *CHD2,* a chromatin-remodeling gene, are associated with increased risk for autism spectrum disorder (ASD) and epileptic encephalopathy (Carvill et al., 2013; O'Roak et al., 2014). Case reports have identified individuals with *CHD2* mutations who present with neurodevelopmental problems including ASD, intellectual disability (ID), seizures, and challenging behavior, but substantial diversity is present across phenotypes (Chénier et al., 2014; Kim et al., 2018). Mice with *CHD2* mutations present with reduced body weight and spinal curvature, and these features have been reported in some humans; however, a characteristic physical phenotype of *CHD2* mutations has not been established in humans (Chénier et al., 2014; Kim et al., 2018). Quantitative phenotyping of individuals with *de novo CHD2* mutations is necessary to understand how these events contribute to neurodevelopmental disorders and comorbid behavioral and medical problems.

Objectives: To characterize the human phenotype of *CHD2* mutations using quantitative data from medical and behavioral evaluations.

Methods: Participants were 10 individuals with disruptive *de novo CHD2* mutations: Four individuals drawn from an ongoing genetics-first study, two individuals from the Simons Simplex Collection (SSC), and four individuals from published studies identified through denovo-db (2018; Epi4K Consortium et al., 2013; O'Roak et al., 2014; Rauch et al., 2012; Willsey et al., 2017). Participants in SSC and the ongoing study completed diagnostic assessments, medical history interviews, and physical and dysmorphology exams.

Results: 70% of individuals with disruptive *de novo CHD2* mutations were diagnosed with ASD, 60% were diagnosed with ID, and 56% were diagnosed with an anxiety disorder. 75% reported seizures. Gastrointestinal problems were reported by 100% of participants who completed a medical history interview; sleep problems were also reported by 100% of participants with a medical history. Spinal problems were not reported in any cases. Internalizing behavior problems were in the clinical range, while externalizing problems were in the borderline range; a history of aggression toward caregivers is reported for 83% of participants. Substantial variability is present in verbal IQ, nonverbal IQ, and adaptive behavior. 83% of individuals presented with a body mass index (BMI) one or more standard deviations below the mean, and 50% had a BMI below the 5th percentile.

Conclusions: *CHD2* mutations in humans are characterized by low BMI, sleep and GI problems, internalizing and externalizing behavior problems, high rates of ASD and seizures, and variability in IQ and adaptive behavior. Significant sleep and GI problems are also reported in humans with *CHD8* mutations (Bernier et al., 2014), suggesting that the role of chromatin remodeling in ASD-associated sleep and GI disturbances should be further examined. Other features of the *CHD2* phenotype in humans, such as low body weight and elevated rates of internalizing disorders, differ notably from the *CHD8* phenotype (Bernier et al., 2014). Future research should evaluate associations between *de novo* mutations and comorbid

internalizing disorders as well as the impact of intron mutations in chromatin-remodeling genes.

41 **202.041** Comparative Analysis of ASD Gene Prioritization Strategies

***E. Larsen**, S. Spring-Pearson and S. Banerjee-Basu, MindSpec Inc., McLean, VA*

Background:
Identification of a core set of highly penetrant and causative ASD genes among the growing list of genes associated with the disorder has become a central goal in autism research. To that end, we have developed a gene-scoring algorithm that relies on ongoing curation of individual ASD-associated variants in the autism genetic database (AutDB). The assessment of ASD-associated variants is based on multiple parameters such as significance of genetic association, family structure, inheritance pattern, zygosity, variant type, and functional effect (Larsen et al., 2016).

Objectives:

Our gene-scoring algorithm is one of several prioritization strategies that have emerged to aid in the identification of a core set of likely pathogenic ASD genes. However, there are differences between the approaches by which these strategies identify their own unique gene sets. Here, we utilized a modified version of our gene-scoring algorithm and compared our findings to other available ASD candidate gene datasets.

Methods:

We analyzed a total of 13,120 individual variants in 1036 genes associated with ASD that were annotated from 3544 research articles (AutDB data freeze of September 2018) in order to prioritize ASD candidate genes and identify a set of high-confidence genes. We then compared the results of our prioritization analysis to five other available ASD gene datasets: the SFARI Gene Scoring Module (data freeze of September 2018); a dataset of 65 ASD candidate genes identified by TADA analysis of whole-exome sequencing data (Sanders et al., 2015); candidate genes identified by a human brain-specific functional interaction network (Krishnan et al., 2016); the Developmental Brain Database (Gonzales-Mantilla et al., 2016); and the 78 genes comprising the SPARK gene list (updated April 2017).

Results:

The majority of the highest ranking ASD genes identified by our gene-scoring algorithm were well represented in four out of five datasets analyzed in this study. However, we also observed significant differences between our results and the other datasets, in part due to the types of genetic evidence used in assessing the importance of a gene in ASD pathogenesis, as well as to the dynamic assessment of candidate genes made possible by real-time curation of ASD-associated variants in AutDB. Finally, we observed little overlap between our results and those reported in Krishnan et al., 2016, with only 5 of our high confidence ASD genes ranked within the top 100 genes identified by interaction networks.

Conclusions:

The gene prioritization strategies used here help to confirm the importance of a set of genes well-represented by other authors and other methodologies while also highlighting genes for which some strong evidence exists that is suggestive of their causative role in autism but which have been overlooked by other methods.

42 **202.042** Contactin-5 Copy-Number Variant Is an Inherited Risk Factor for Autism Spectrum Disorder

***Z. Schmilovich**[1,2], G. Huguet[3,4], Q. He[5], E. A. Douard[3], S. Jacquemont[6,7], P. A. Dion[2,8], L. Xiong[9], G. A. Rouleau[1,2,8] and B. Chaumette[1,2], (1)Human Genetics, McGill University, Montreal, QC, Canada, (2)Montreal Neurological Institute and Hospital, Montreal, QC, Canada, (3)Research Center of UHC Sainte-Justine, Montreal, QC, Canada, (4)University of Montreal, Montreal, QC, Canada, (5)Université de Montréal, Montreal, QC, Canada, (6)CHU Sainte Justine, University of Montreal, Montreal, QC, Canada, (7)Service of Medical Genetics, CHUV, Lausanne, Switzerland, (8)Neurology and Neurosurgery, McGill University, Montreal, QC, Canada, (9)Montreal Neurological Institute, McGill University, Montreal, QC, Canada*

Background: The genetic contribution of Autism is high with a heritability of 60%. Identifying the genetic factors associated with this disorder is limited by its polymorphic and genetic heterogeneity. Genetic research has focused on rare variants with very large effect size including deletions and duplications of the genome, known as copy-number variants (CNVs). CNVs with intermediate effect size also play a less understood role in the underlying genetic architecture of the disorder. A multiplex family with three affected children with Autism Spectrum Disorder (ASD), a sibling with a neurodevelopmental condition, and an unaffected father were reported to all be carrying a CNV in the *Contactin-5 (CNTN5)* gene. The protein products of *CNTN5* encodes a neuronal cell adhesion molecule and promotes neurite outgrowth, suggesting the gene's potential role in brain disorders, however, its impact has not yet been demonstrated.
Objectives: This study aims to determine whether CNVs in this gene contribute to the risk for ASD. We examine the penetrance and prevalence of *CNTN5* CNVs in affected individuals with ASD and their unaffected siblings, as well as the general population.

Methods: Bioinformatic tools were used to explore six distinct databases. Microarray data from the Simon Simplex Collection (SSC) (n=2587) was used to distinguish *CNTN5* CNV prevalence between probands with ASD and their unaffected siblings. A novel structural variant segregation script identified the variant's inheritance pattern. Generation Scotland and IMAGEN databases (n=7511) were used to compare the prevalence of *CNTN5* CNVs between probands and the general population. Copy-number variants from Montreal's Ste-Justine Hospital (n=16,000) were used to validate the SSC data findings. DECIPHER, a database of individuals (n=27,000) with rare genetic diseases, was used to determine the frequency of *de novo* CNVs. Database of Genomic Variants (DGV) was used to determine the frequency of *CNTN5* CNVs within the general population.

Results: A significant overrepresentation of deletion CNVs within the exonic region of *CNTN5* in the probands (n=4/2587) from the SSC, compared to the general population (n=1/7511) (Fisher test p=0.01, Odds Ratio:11.6), was identified. The prevalence of deletion *CNTN5* CNVs in ASD probands and their unaffected siblings in the SSC cohort is 0.15%. An identical incomplete penetrance pattern of *CNTN5* variants compared to the reported multiplex family was observed in the SSC database. All (n=4) of the deletion *CNTN5* CNVs in the probands from the SSC were inherited from phenotypically normal parents; none arose *de novo*. Incomplete penetrance was noted, as CNVs in *CNTN5* were observed in both probands and their unaffected siblings. Interestingly, analysis of the DECIPHER database suggests that 52.6% of the CNV deletions and duplications of *CNTN5* (n=10/19) seen in individuals with rare disorders, ranging from 41.64kB to 134.05Mb, arise *de novo*.

Conclusions: *CNTN5* CNVs contribute to an individual's overall risk for autism. Such variants with intermediate frequency and penetrance reveal part of the underlying genetic architecture of ASD that has been largely unexplored. By studying these intermediate variants, the total genetic profile of individuals with ASD can be better understood, leading to improved genetic diagnostic techniques and future therapeutics.

43 **202.043** Contribution of Multiple Inherited and Shared Rare Variants to Autism Spectrum Disorder (ASD) in a Family with 3 Affected Siblings

*Y. Qiao[1], K. Calli[2], S. Martell[3], S. Race[2], C. Chijiwa[2], A. Glodjo[4], S. Jones[5], S. W. Scherer[6], E. Rajcan-Separovic[2] and **M. S. Lewis**[2], (1)Unversity of British Columbia, Vancouver, BC, Canada, (2)University of British Columbia, Vancouver, BC, Canada, (3)Medical Genetics, University of British Columbia, Vancouver, BC, Canada, (4)Sunny Hill Health Centre for Children, Vancouver, BC, Canada, (5)3Canada's Michael Smith Genome Sciences Centre, Vancouver, BC, Canada, (6)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Familial rare mutations can be found in 3-5% of ASDs. However, how they contribute to ASD remains largely unknown. As part of the iTARGET Autism project (http://www.itargetautism.ca/) and the MSSNG project (https://www.mss.ng/), we have recruited multiple families with ≥3 affected children to address this question.

Objectives: To analyze the genotype-phenotype correlation of inherited rare mutations shared by affected children in a multiplex ASD family.

Methods: We used whole genome sequencing (WGS) and high resolution DNA microarray to detect inherited rare mutations (SNVs, Indels, and CNVs) in a multiplex family with 3 affected children.

Results:

(1). Clinical investigations: This family has 3 boys all affected with ASD. Boy-1 (14-54A, 15 y/o) has ADHD, anemia, decreased pain sense, and no outwardly syndromic features. Boy-2 (14-53A, 14 y/o) has slightly coarse facies, showing the most obvious cognitive deficits and greater severity of ASD, and no anemia (nor a thalassemia). Boy-3 ('14-55A, 8 y/o) has anemia since birth, astigmatism and no outwardly syndromic features. Family history: Dad is an α-thalassemia carrier; Dad's nephew has PDD-NOS. Mom is a β-thalassemia carrier. Mom's father is anemic with Asperger's syndrome. Mom's paternal aunt and uncle both exhibit symptoms of OCD and anxiety disorder (unconfirmed).

(2). CNVs findings: An 18Kb deletion involving *HBA1, HBA2, HBQ1* and *HBM* (alpha hemoglobin locus) was identified in Boy-1 by DNA microarray. WGS confirmed this deletion was from the father. Array results for Boy-2 and Boy-3 are normal.

(3). SNVs/Indels findings: Two inherited, likely pathogenic rare variants were found in all 3 affected boys: compound heterozygous variants in *RELN* (p.Val1153Ile and p.Ser630Arg) and a maternal missense variant in *SHANK2* (p.Pro1184Ser). They are each strong ASD risk genes with both de novo and inherited mutations frequently found in affected or unaffected parents, suggesting other genetic or epistatic factors may co-act to cause ASD. Further to this hypothesis, additional gene variants are shared by all 3 boys, including compound heterozygous variants in *SCN10A*, maternal variants in *DLG1*, and paternal variants in *KMT2C*. Although these individual variants are of uncertain clinical significance, their co-occurrence in all 3 boys with ASD add to the mutation burden potentially predisposing to the ASD in children of parents with positive family histories. We also found a maternal variant in an ASD candidate gene, *ASH1L* (p.Gln433Pro), unique to Boy-2. Whether this missense mutation may contribute to the more severe ASD phenotype in this boy needs further investigation. A maternal pathogenic LOF mutation in *HBB* (c.126_129delCTTT, p.Phe42Leufs) was identified in Boy-3 as his mother is a β -thalassemia carrier. A *HBA1/HBA2*-involved deletion was found in Boy-1 and his father (an α -thalassemia carrier). Both Boy-1 and Boy-3 have anemia, while Boy-2, without anemia, does not have either of these two mutations.

Conclusions: Multiple inherited rare mutations, each with subthreshold or subtle clinical impact, may collectively contribute an additive effect or provide a 2nd-hit, or multiple-hits to render pathogenicity in ASDs.

44 **202.044** Demographic and Clinical Characterization of Participants in the Australian Autism Biobank

***G. A. Alvares**[1,2] and T. Australian Autism Biobank Team[2], (1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia*

Background: The clinical and genetic heterogeneity within individuals diagnosed with Autism Spectrum Disorder (ASD) represents significant challenges to advancing knowledge about etiological pathways and clinical outcomes. Considerable progress in this area has been made through collaborative and large-scale projects, necessitating a similarly large resource to be established in Australia, a country with unique ethnic and cultural diversity. Established in 2014, the Australian Autism Biobank was initiated by the Cooperative Research Centre for Living with Autism (Autism CRC).

Objectives: To summarise the clinical and demographic features of participants recruited to participate in the Australian Autism Biobank.

Methods: Participants recruited were children with a diagnosis of ASD, aged between 2-17 years, at four data collection sites across Australia. Biological parents and siblings, both with and without ASD, were also invited to participate, as well as non-autistic children ('controls') recruited from the general community. A smaller group of children presenting to recruitment sites clinically referred for an ASD diagnostic evaluation but who did not meet diagnostic criteria were also invited to participate ('ASD-query'). No exclusion criteria regarding language level, cognitive ability, or comorbid medical, psychiatric or genetic condition was applied to children diagnosed with ASD. All children completed cognitive or developmental assessments, with probands and ASD-query children additionally completing ASD assessments. Parents/caregivers completed questionnaires about medical and developmental history. Physical measurements as well as blood, stool, urine, and hair samples were collected from children; physical measurements and blood samples were collected from both parents of probands.

Results: A total of 979 probands (first child in family diagnosed with ASD) participated (20.4% females, 83.4% Caucasian, 12.9% Asian, 1.7% Aboriginal, 2.0% Maori or Pacific Islander), with an average age of 7.4±3.9 years (mean±SD) at assessment. 173 autistic siblings were also recruited (7.8±3.5 years, 30.1% females), comprising 145 multiplex families (between 2-5 children diagnosed) and 27 twin pairs. 847 mothers (39.5±6.4 years, range 22-68 years), 548 fathers (42.1±7.5 years, range 19-82 years) and 263 non-autistic siblings (8.2±4.2 years, range 2-16, 51% females) also participated. 150 non-autistic controls (6.2±3.4 years, 2-15 years, 51% female) and 16 ASD-query children (6.1±2.6, 3-10 years, 50% female) were also included in the cohort. Within the proband group, age at diagnosis ranged from 12-211 months (55.7±34.7) and IQ scores ranged from 40-138 (79.5±23.3). Based on parent/caregiver reports, 31.4% of probands had a diagnosed Intellectual Disability or Global Developmental Delay (n = 311), 4.5% had epilepsy (n = 45), and 2.2% had a previously diagnosed genetic condition (n = 22).

Conclusions: This initiative has resulted in a valuable and detailed resource comprising clinical information alongside biological samples to help increase our understanding of the underlying mechanisms associated with an ASD diagnosis. Both phenotypic and biological data are now available for access requests from the research community.

45 **202.045** Diagnostic Whole Exome Sequencing in an Autism Research Population

M. Mulhern[1], *S. De Rubeis*[2], *L. Tang*[1], *M. P. Trelles*[1], *A. Kolevzon*[1] *and J. Buxbaum*[3], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background:

Whole exome sequencing (WES) is increasingly being used clinically to identify a genetic etiology for autism spectrum disorder (ASD). Studies have shown the diagnostic yield for WES in ASD is around 25% in the clinical laboratory setting, but can be as low as 3.1% for those with isolated ASD. At our ASD focused research center, research WES is offered to all participants who have a confirmed diagnosis of ASD without a known genetic cause, regardless of lack of co-morbid medical conditions or insurance coverage. As clinicians consider what genetic testing is appropriate for their patients and as professional organizations update guidelines around genetic testing for ASD, it will be important to consider results from broader ASD populations beyond those referred for clinical WES.

Objectives:

To assess the diagnostic yield of WES in a broad ASD population from a research center and to describe the genetic findings identified.

Methods:

Participants underwent gold standard diagnostic evaluations for ASD and met both clinical and research criteria for this condition. Informed consent was obtained, and research WES was performed on the trio (proband and both parents) or quad (including a sibling). Qualifying variants were reviewed by a multidisciplinary team of researchers based on guidelines provided by the American College of Medical Genetics, and those variants determined to be likely contributory to the participant's ASD phenotype were sent for confirmation in a CLIA-approved laboratory.

Results:

In eighty-nine families, six sequence variants were determined by the research team to be likely causal, for an overall diagnostic yield of 6.7%. Four *de novo* variants in the genes *MECP2*, *HIVEP2*, *SHANK3* and *CHD8* were classified by the CLIA-laboratory as likely pathogenic or pathogenic. A maternally inherited missense variant in the X-linked gene *IQSEC2* and a *de novo* missense variant in the recently described gene *MED13* were both classified as variants of uncertain significance (VUS). Including only clinically classified pathogenic and likely pathogenic variants, the diagnostic yield was 4.5%.

Conclusions:

Diagnostic yield in a general ASD research population is much lower than in those referred for clinical testing, likely because cases with ASD referred for clinical WES might be biased towards those with a more severe or complex phenotype. The results of this study are likely more representative of the general ASD population. Challenges highlighted in this study include interpretation of previously unreported missense variants in X-linked genes, as these will frequently be classified as VUS (e.g., *IQSEC2*). This challenge extends to providing meaningful genetic counseling to mothers who are found to be carriers for a VUS in an X-linked gene. Another challenge is interpretation of, and genetic counseling for, variants identified in newly described genes, such as *MED13*, where only 13 affected individuals have been described in one publication. On the other hand, with well-studied genes such as *MECP2* and *SHANK3,* a genetic diagnosis provides families the opportunity to connect with robust family communities and participate in clinical trials and research, and allows for thorough recurrence risk counseling.

46 **202.046** Diagnostic Yield of Chromosomal Microarray Analysis in Autism Spectrum Disorder

F. Cucinotta[1], *A. Ricciardello*[1], *L. Turriziani*[1], *M. Briguglio*[1], *M. Boncoddo*[1], *F. Bellomo*[1], *M. Baccarin*[2], *C. Picinelli*[2], *P. Castronovo*[2], *P. Tomaiuolo*[2], *C. Lintas*[3], *R. Sacco*[3], *S. Gabriele*[3], *M. Canali*[3] *and A. M. Persico*[1,2], *(1)Interdepartmental Program "Autism 0-90", "G. Martino" University Hospital, University of Messina, Messina, Italy, (2)Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy, (3)Service for Neurodevelopmental Disorders & Laboratory of Molecular Psychiatry and Neurogenetics, University "Campus Bio-Medico", Rome, Italy*

Background: The genetic underpinnings of Autism Spectrum Disorder (ASD) are very heterogeneous and can range from monogenic and syndromic cases to oligogenic/polygenic forms. Rare and common copy number variants (CNVs) can contribute to the aetiology of the disorder and differences in CNV burden can contribute to the substantial clinical heterogeneity observed in ASD. For this reason, array-CGH have become a first-tier diagnostic test in the medical work-up of autistic individuals.

Objectives: The aim of this study is to identify pathogenetically-relevant CNVs in 254 ASD families (217 simplex and 37 multiplex) and to verify rates of *de novo* vs inherited pathogenic CNVs.

Methods: A total of 275 ASD subjects from 217 simplex and 37 multiplex families were consecutively admitted to the Service for Neurodevelopmental Disorders at Campus Bio-Medico University Hospital (Rome, Italy) and to the Interdepartmental Program "Autism 0-90" at the "G. Martino" University Hospital (Messina, Italy), between the years 2015 – 2017. Blood was drawn from patients and first-degree relatives, DNA was extracted from leukocytes and array-CGH analysis was performed using the Human Genome CGH SurePrint G3 Microarray 4 x 180K Kit (Agilent). Array-CGH outcomes were blindly classified by four authors according to five different categories ranging from "absence of functionally relevant CNVs" to "certainly causal CNV". Data were imported on a MySQL RDBMS instance and analyzed through SQL queries.

Results: "Certainly causal CNVs" and "probably causal CNVs" were detected in 22/275 (8.0%) and in 44/275 (16.0%) ASD patients, respectively. The frequency of duplications and deletions is comparable. However, "certainly causal CNVs" are significantly more often *de novo* (Chi sq. 8.46; 2 d.f., P<0.05), and in particular *de novo* deletions, as compared to inherited deletions (Chi sq. = 14.28; 2 d.f., P<0.001) or to *de novo* duplications which are not significantly increased in frequency compared to inherited duplications. On the other hand, rare duplications are significantly more often "certainly causal" than "probably" or "possibly causal" (Chi sq. 10.97; 2 d.f., P<0.01), regardless of being *de novo* or inherited. Furthermore, paternal transmissions of rare "certainly causal CNVs" are significantly enhanced compared to maternal transmissions of rare "certainly causal CNVs" and to paternal transmissions of less pathogenic CNVs (Chi sq. 7.58; 2 d.f., P<0.05). Finally, CNVs recurrent in ASD are present in 25/66 (37.9%) patients carrying "probably" or "certainly causal CNVs".

Conclusions: Array CGH identified certainly or probably pathogenic CNVs in 66/275 (24.0%) ASD patients in our sample, confirming their high diagnostic yield. Significant contributions to ASD risk come from *de novo* deletions, from rare recurrent CNVs, and from paternally transmitted CNVs, supporting the variable penetrance of many pathogenic CNVs, especially duplications, in the ASD spectrum. Recurrent CNVs, though explaining a minority of cases, may provide more reliable opportunities to elucidate disease-relevant mechanisms.

47 **202.047** Differences in the Genetic Background Contribute to Risk and Resilience to Autism

*T. Rolland[1], **T. Bourgeron**[2], F. Cliquet[1], A. Mathieu[1], C. Leblond[3], F. Amsellem[4] and R. Delorme[5], (1)Institut Pasteur, Paris, France, (2)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (3)Institut PASTEUR, Paris, France, (4)Pasteur, Paris, France, (5)Pasteur Institute, Human Genetic and cognitive function, Paris, France*

Background: In the last 20 years, there was a tremendous progress in identifying genes associated to autism spectrum disorders (ASD). The genetic architecture of ASD is complex, ranging from apparently monogenic forms of the disorder to highly polygenic forms. However, if rare deleterious mutations affecting approximately 100 genes are now well accepted as risk factors for ASD, the role of the genetic background on their variable penetrance remains poorly understood.
Objectives: To identify resilient individuals, carrying rare deleterious mutations in ASD susceptibility genes without being diagnosed with the condition, and study the genetic factors influencing their clinical trajectories.

Methods: We designed a framework to assess the risk associated to more than 11,000 rare deleterious mutations in parents and children of 1,786 quadruplet families with one affected and one unaffected child of the Simons Simplex Collection. We investigated hallmarks of mutation intolerance (haploinsufficiency, probability of loss-of-function mutation intolerance, z-score for missense mutation or deletion intolerance) to discriminate mutations likely to affect gene function. We also used clinical records available for each family to focus on mutations identified in children displaying a clear discordance in ASD phenotype (SRS and VABS-II scores).

Results: The fraction of resilient individuals among siblings and parents was surprisingly high, with approximately 7% of individuals carrying rare deleterious mutations in ASD-associated genes without displaying ASD symptoms. By stratifying resilient children from other unaffected children, we confirm a significant role of polygenic risk in ASD etiology. In addition, we observe significant differences in polygenic risk between affected and unaffected children who inherited the same rare deleterious mutations and between affected children with rare inherited deleterious mutations and affected children without.

Conclusions: The genetic background significantly influences the clinical trajectory of siblings carrying similar deleterious mutations in ASD-associated genes. Our results highlight the importance of investigating rare deleterious mutations in ASD susceptibility genes in the context of the genetic background, as well as the clinical heterogeneity of both diagnosed and undiagnosed individuals. Understanding the genetic factors contributing to resilience to ASD provides new insights into the molecular mechanisms of ASD, ultimately allowing the development of novel therapeutic strategies.

48 **202.048** Enhancing Impact of Genomics Research in ASD through Integration of Research Results into Routine Care Pathways – a Case Series

***I. Peltekova**[1], D. Buhas[2,3], L. Stern[4], E. Kirby[5], A. Yusuf[6] and M. Elsabbagh[7], (1)McGill University, Montreal, QC, CANADA, (2)Clinical Genetics, McGill University, Montreal, QC, Canada, (3)Clinical Genetics, Montreal Children's Hospital, Montreal, QC, Canada, (4)Montreal Children's Hospital, Montreal, QC, Canada, (5)Public Population Project in Genomics and Society, Montreal, QC, Canada, (6)Psychiatry, McGill University, Montreal, QC, Canada, (7)McGill University, Montreal, PQ, Canada*

Background: When used in a research context, results from genetic tests, like microarray, whole exome sequencing (WES) and whole genome sequencing (WGS), accelerate discovery of new genetic variants associated with Autism Spectrum Disorder (ASD). However, the return of genetic results (RoR) to participants remains a complex and nuanced process. There are no specific recommendations on which research genetic results should be communicated, and their management with respect to the participants' healthcare. Furthermore, approaches may differ across different jurisdictions and institutions. Research teams may rely on clinical recommendations, which are limited in scope. This lack of practical recommendations for RoR from genetic research in ASD may result in variable practices by research teams.
Objectives: We empirically investigated the challenges of returning genetic research results to individual participants, enrolled in genomics studies in ASD. We used systematic guiding principles drawn from the existing literature to facilitate the RoR process and aide the integration of genetic research results into clinical care for participants.

Methods: We report a case series (n = 16) involving the return of genetic results to research participants in large genomics studies in ASD, who were enrolled as children. We convened a work group of specialists that drew on relevant literature and their expertise in devising principles that would guide RoR. We implemented the principles in our RoR process to return genetic research results to participants and to integrate these results into their healthcare.

Results: The case-series demonstrates the ethical, clinical and practical challenges of RoR in ASD genomic studies for participants enrolled as children. The average time between enrolment and availability of a genetic research result was 5.5 years. At the time of RoR, the age of the participants ranged from 6 to 24 years; 6 of the participants had reached adulthood by the time of RoR. The majority of the research genetic results (n = 11) were CNVs, one revealed aneuploidy, and the remainder were SNVs. Most genetic changes were identified to be on chromosomes 1, 15 and 16. The majority of genetic changes (n = 10) occurred *de novo*. In 4 or the 16 cases specific challenges emerged in terms of communication of the results and/or their integration in clinical care pathways.

Conclusions: Our findings highlight that optimal use of genetic research results relies on their integration into individualized care pathways for participants. Ultimately, this approach can bridge the existing gap between research and healthcare in the management of complex genetic research results in ASD.

49 **202.049** Examining the Broader Autism Phenotype in the Context of Genetic Etiology

***C. M. Hudac**[1], J. Gerdts[1], T. Turner[2], E. E. Eichler[3] and R. Bernier[1], (1)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)Department of Genome Science, University of Washington, Seattle, WA*

Background:
Considering the phenotypic heterogeneity within autism spectrum disorder (ASD), children's individual differences may relate to subclinical parental traits associated with ASD symptoms and social impairment, known as the broader autism phenotype (BAP; Bolton et al., 1994). However, the extent by which parents' genetic contributions interact with BAP contributions is unclear. One hypothesis is that parents with an ASD-

associated genetic event (e.g., disruptive single gene mutation, rare copy number variations) will present with an elevated rate of BAP and other social problems, and their child's ASD symptoms will be more severe.

Objectives:

We examined the extent to which parental BAP is associated with children's genetic etiology, specifically as it pertains to rare inherited genetic events relative to children with other disruptive *de novo* genetic events.

Methods:

Local participants (*N* = 105) were parents of a child with an ASD diagnosis who completed either the Simons Simplex Collection (*n* = 77) and/or a genetics-first study ("TIGER", *n* = 28) in which a parental phenotyping battery included three measures related to ASD symptoms of social impairment (see Table 1). Parents were grouped based upon their child's genetic etiology. Given the aim of investigating clinical observations of BAP, we focused on the Broader Phenotype Autism Symptom Scale (BPASS, Dawson et al., 2007), a clinical interview capturing social motivation and flexibility, as well as nonverbal social behaviors such at expressiveness and conversational skills. ANOVAs tested group differences (Tukey correction for planned comparisons). Pearson correlations tested for BAP parent-child associations with critical ASD symptoms.

Results:

There were no group differences in age, full-scale IQ, BPASS total, or BAPQ total, *p*'s > .62. Regarding clinical observations, all parents were observed within the normal range in expressiveness and conversational skills, with good to moderate facial expressions. Group differences indicated that the De Novo group exhibited elevated problems with sociability in groups, $F(2,82) = 3.22$, $p = .045$, relative to the Inherited group. Low or abnormal parents' group sociability was related to similar problems in probands' social and adaptive abilities (see Figure 1), as noted by SRS-II subdomains, VABS-III composite, and VABS-III subdomains, but not the SRS-II overall t-score. Of note, the De Novo group exhibited weaker associations between parental BAP and proband ASD symptomology relative to the Inherited group (e.g., VABS-II composite: De Novo $r = -.11$, Inherited $r = -.21$).

Conclusions:

Contrary to hypotheses, parents in the Inherited group that share a rare ASD-risk genetic event with their child did not exhibit elevated BAP symptoms. Yet, parental sociability in groups was associated with proband ASD symptomology to a greater extent for Inherited relative to De Novo parents, aligned with our initial prediction of more severe ASD symptoms for children whose parents have both BAP symptoms and are the source of that child's genetic etiology. A better understanding of the severity of specific genetic events (Woodbury-Smith, et al., 2018) combined with this work in understanding individual BAP differences may elucidate appropriate identification and treatment options (Gerdts et al., 2013).

50 **202.050** Habituation to Social Information Is Associated with Repetitive Behavior in 16p11.2 Deletion and Duplication

ABSTRACT WITHDRAWN

Background: Recurrent copy number variations (CNVs) at the 16p11.2 locus (Weiss et al., 2008) are associated with autism spectrum disorder (ASD) and ASD symptoms (Hanson et al., 2015), including social difficulties and increased restricted and repetitive behaviors (RRBs). At the neural level, individuals with 16p11.2 CNVs exhibit atypical social information processing such that rapid habituation to social information is evident in 16p11.2 deletion and duplication carriers, opposed to the pattern of rapid nonsocial habituation in typical populations (Hudac et al., 2015). Rapid habituation may indicate lower salience of related stimuli. Lower salience of social information and increased relative response to nonsocial motion in those with 16p11.2 CNVs lead us to hypothesize an increased prevalence of RRBs which may be related to habituation patterns. Objectives: Determine the extent by which social and nonsocial information habituation is associated with RRBs in individuals with 16p11.2 deletion and duplication.

Methods: Participants (N = 329, see Table 1) completed phase 1 of the Simons Variation in Individuals Project (Simons VIP, https://simonsvipconnect.org/), which included in-person clinical, behavioral, and medication characterization. A subset of individuals with 16p11.2 CNVs (N = 21; the majority with fluent verbal skills) also completed neural characterization via electroencephalography in which habituation was established as changes in neural response over time to social and nonsocial stimuli (i.e., moving hands vs tubes). First, we quantified RRBs in 16p11.2 CNVs as reflected by the ADOS scores including calibrated severity score (CSS; total, social affect, restricted and repetitive behavior) and compared between individuals with 16p11.2 deletion (DEL) and 16p11.2 duplication (DUP). Second, we extended prior analyses by investigating the relationship between RRBs and social habituation using multilevel analyses with Tukey correction for multiple comparisons.

Results: As a group, DEL carriers and DUP carriers did not demonstrate significant differences in CSS scores; however, when considering only those without fluent speech (*n* = 81), the DEL carriers showed a significantly higher ratio of repetitive behavior relative to their social difficulties compared to DUP carriers, $p = .002$. Regarding habituation, DUP carriers with more RRBs habituated more rapidly to social motion (i.e., positive slope in Figure 1), $r = .71$, $p = .031$, while DEL carriers with more RRBs sensitized to social motion (i.e., negative slope in Figure 1), $r = -.59$, $p = .046$. Habituation to nonsocial motion was not related to RRBs in 16p11.2 carriers, *p*'s > .66.

Conclusions: Distinct social habituation patterns related to RRB severity were found for those with 16p.11.2 deletions and duplications. Sensitization to social motion, as found for the DEL carriers may indicate either an initial delay in processing social information or potentially increasing engagement with social information over time (Hudac et al., 2015; 2017; Jones et al., 2016). Individuals with deletions and without fluent speech language also show increased relative severity of RRBs; habituation studies may help to explain differing rates.

51 **202.051** Identification of Multiple Candidate Variants in a Family with Autism Spectrum Disorder through Whole Genome Sequencing Analysis

*M. S. Lewis[1], K. Calli[1], **Y. Qiao**[2], R. K. Yuen[3], R. M. Stowe[4], S. Martell[5], C. Chijiwa[1], E. Rajcan-Separovic[1] and S. W. Scherer[3], (1)University of British Columbia, Vancouver, BC, Canada, (2)Unversity of British Columbia, Vancouver, BC, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada, (4)Psychiatry and Medicine (Neurology), University of British Columbia, Vancouver, BC, Canada, (5)Medical Genetics, University of British Columbia, Vancouver, BC, Canada*

Background: Whole genome sequencing (WGS) has been more widely used as a tool in the clinical diagnosis and it helps increase the diagnosis rate up to 20% in autism spectrum disorders (ASDs). Thus far, more than 100 genes and CNV loci have been reported to be associated with ASD suscpeptibility. However, none are found in >1% of cases with ASDs, suggesting a diverse genetic heterogeneity of the disorders.
Objectives: To identify a putative genetic cause of an individual's ASD.

Methods: WGS in a trio ASD family in combination with internal bioinformatics pipelines and a commercial software VarSeq.

Results: We identified 4 inherited rare damaging missense single nucleotide variants (SNVs) in 4 genes (DNMT3A, PHF2, NRXN2, and SNRPN), and one rare copy number variant (CNV). The CNV is a paternally inherited 14 Kb microdeletion in ZNF517, which is also confirmed by DNA microarray.The variants in DNMT3A and SNRPN were also confirmed by Sanger sequencing. Clinically, the male proband has ASD, moderate intellectual disability, developmental delay, verbal apraxia, post-natal macrocephaly, large stature, adult-onset epilepsy (age 22 years), and mild facial dysmorphism (round facies, bitemporal narrowing, narrow palpebral fissures, low-set and protuberant ears, hypotonia, high arched palate). Neither parent has intellectual disability or ASD, though the father has macrocephaly and over-growth. All of the genes involved in these rare variants and CNV are reported to be ASD-related and involved in brain/neuron development. De novo mutations in the above SNV genes and a recurrent deletion in ZNF517 gene have been identified in cases with ASDs. In our proband, mutations in DNMT3A, PHF2, and SNRPN are paternally inherited while NRXN2 is maternal. DNMT3A is a newly identified ASD candidate gene and its mutation is associated with Tatton-Brown-Rahman Syndrome. Some of the phenotypes are shared in our proband. Functional analysis is in progress including whole transcriptome analyses.

Conclusions: DNMT3A is likely the most relevant gene accounting for both ASD and features concordant with Tattan-Brown-Rahman syndrome. Alternatively, our subject's ASD phenotype reflects a collection of quantitative phenotypic traits associated with each of the multiple ASD risk genes identified and its complex genetic origins.

52 **202.052** Parents' Perceived Utility of Biological Testing Prior to Clinical Genetic Testing Is Associated with Child Emotional and Behavioural Functioning, Family Functioning, and Family-Centered Care

A. Yusuf[1], *I. Peltekova*[2], *R. Bruno*[3], *J. Frei*[3], *T. Savion-Lemieux*[3], *J. Howe*[4], *S. W. Scherer*[4] *and M. Elsabbagh*[5], *(1)Psychiatry, McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, CANADA, (3)Research Institute-McGill University Health Centre, Montreal, QC, Canada, (4)The Hospital for Sick Children, Toronto, ON, Canada, (5)McGill University, Montreal, PQ, Canada*

Background:
Chromosomal microarray (CMA) testing has been integrated into routine clinical workup in Autism Spectrum Disorder (ASD) based on improved diagnostic yields. However, its *clinical utility* is unclear considering that results have not led to improvements of health outcomes for all. Establishing the clinical utility of CMA would thus require evaluating the value of information expected from the test as perceived by individuals receiving the test and their families.

Evidence provides a mixed picture of parents' perspectives on genetic testing in ASD, with indications that perceived utility prior to testing and experienced impact following results to be distinct constructs. Given the heterogeneous nature of the target population, the inconsistency of findings can also be attributed to underpowered studies with issues in sampling. Most importantly, a valid measure of perceived utility and its predictors are missing.

Objectives:

We aimed to examine the association between the parents' perceived utility of biological testing and its potential predictors: child's severity of symptoms and functioning, parent stress, family functioning, and appraisal of family-centered care, while controlling for sociodemographic factors within a representative sample of families around the time of their child's diagnosis using a new quantitative measure of perceived utility.

Methods:

Families were invited to participate in an ongoing prospective cohort, *ASD Genome to Outcome,* following their child's diagnosis. Prior to undergoing clinical genetic testing, families completed the Perceived Utility of Biotesting questionnaire along with self-reported measures (n = 75).

Results:

We entered the following as predictors of interest in a stepwise regression model predicting perceived utility: respondent age, education, household income, child gender and age, child severity of social symptoms, child emotional and behavioural problems, parent stress, family functioning problems, and family-centered care. The best-fitting model accounts for 25% of the variance in perceived utility of biotesting, $F(3, 68) = 8.95$, $p < 0.001$, R^2-*adjusted* = 0.25. Lower child emotional and behavioral functioning, higher family functioning, and lower levels of family-centered care significantly predict greater perceived utility. No other factors were associated with perceived utility.

Conclusions:

Our results suggest that perceived utility of biotesting is determined by families' unmet needs: families who have a child with more emotional and behavioural problems, and who are receiving lower levels of family-centered care, may be more likely to expect testing to address these needs. By identifying how characteristics of each child, family, and their reported experience with routine health services affect the perceived clinical utility of genetic testing, we demonstrated how the current and future potential of genetic testing in particular and biological testing in general can be systematically assessed in the context of *routine care pathways*. We conclude that establishing the clinical utility of biotesting requires family input, not only to improve the impact of current biological tests but also to determine the readiness of potential biological tests for clinical use. This would allow for engagement of families in biotesting development and implementation, and subsequently towards improving the relevance and impact of research and care for families.

53 **202.053** Phenotypic Effects of Loss of Function CNTNAP2 Variants

C. M. Taylor[1], *M. Mitchel*[2], *M. Kinney*[1], *B. Haas-Givler*[1], *K. Brigatti*[3], *M. Young*[3] *and K. Strauss*[3], *(1)Geisinger, Lewisburg, PA, (2)Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA, (3)Clinic for Special Children, Strasburg, PA*

Background: *CNTNAP2* is an autism spectrum disorder (ASD) candidate gene that encodes CASPR2, a large protein expressed in the nervous system. Heterozygous *CNTNAP2* variants have been reported in individuals with ASD and speech-language disorders; however, these variants are frequently inherited, making it difficult to interpret their functional relevance. We have the unique opportunity to study Mennonite and Amish families that harbor a truncating, loss of function (LoF) mutation in *CNTNAP2*. Individuals who are homozygous for this variant present with cortical dysplasia-focal epilepsy syndrome (CDFE), characterized by epilepsy, intellectual disability, and ASD. No studies to date include a detailed assessment of the behavioral phenotype of CDFE in homozygotes nor the potential neurocognitive effects of this *CNTNAP2* variant in their heterozygous carrier relatives.

Objectives: In the current study, we conducted behavioral assessments to phenotype individuals who are homozygous and heterozygous for *CNTNAP2* LoF variants and compared results to their homozygous relatives without the variant. By advancing our understanding of the effects of rare LoF variants in *CNTNAP2*, we hope to elucidate an important mechanistic pathway in ASD.

Methods: We completed phenotypic batteries on four Old Order Amish and Mennonite families consisting of at least one child with CDFE. The phenotypic battery included developmental/cognitive assessment using the Mullen Scales of Early Learning (MSEL), Differential Ability Scales (DAS-2), or the Wechsler Abbreviated Scales of Intelligence (WASI-2). Speech assessments were also completed and included the Goldman-Fristoe Test of Articulation (GFTA-2) and the non-word repetition task of the Comprehensive Test of Phonological Processing (CTOPP-2). The non-word repetition task is robust measure of language impairment which reliably discriminates between individuals with and without a history of language impairment, including bilingual children from diverse language backgrounds. All children above a chronological and developmental age of 12 months were given the Autism Diagnostic Observation Schedule (ADOS-2) by a research reliable examiner.

Results: Children with CDFE scored in the moderate to profound range of intellectual disability. All verbal children with CDFE had significant phonological disorders as measured by the GFTA, providing new evidence for discrete language pathology in CDFE. Notably, carrier children and adults also performed significantly worse on the CTOPP non-word repetition task compared to non-carrier children (p = .02), providing additional evidence for a mild, intermediate language phenotype in heterozygous *CNTNAP2* carriers. Several carrier siblings had a moderate level of ASD symptoms, as measured by the ADOS-2. Non-carrier siblings did not present with elevated ADOS-2 scores, and their social engagement was judged to be within the typical range.

Conclusions: Using a well-controlled experimental paradigm, we provide compelling evidence of mild language impairment and ASD symptomatology in individuals haploinsufficient for *CNTNAP2,* underscoring the fundamental role of this gene in the development of human language and social behavior.

54 **202.054** Returning Clinical Genetic Results on a Large Scale to Research Participants in SPARK

L. Grosvenor[1]*, P. Feliciano*[1] *and W. K. Chung*[2]*, (1)Simons Foundation, New York, NY, (2)Pediatrics, Columbia University, New York, NY*

Background: A common issue in genomic research is whether investigators have a responsibility to return individual genetic research results to research participants. The National Academy of Medicine Report on Returning Individual Research Results to Participants recommends returning such information when feasible. Returning individual research results builds partnerships with participants, provide them with valuable information, and connects them to communities of individuals with similar characteristics. However, returning results requires additional resources from sponsors and researchers and is particularly challenging for large studies. Understanding the benefits and challenges of these processes is important as the number and size of genomic research studies increase.

Objectives: We sought to build a scalable process for returning genetic results related to the participants' autism spectrum disorder (ASD) diagnosis in participants in SPARK, a large recontactable research cohort of tens of thousands of individuals with ASD and their first-degree family members. Using an online platform and a telehealth genetic counseling service, we have returned individual genetic findings to 21 participants and plan to return approximately 200 results by May 2019.

Methods: 457 families were recruited to SPARK online (https://sparkforautism.org) and provided consent to receive genetic results. Individual genetic results related to autism that met ACMG pathogenic or likely pathogenic criteria were identified in 10.8% of families. A committee of medical geneticists reviewed variant and phenotypic information for all families, and results were confirmed in a CLIA (Clinical Laboratory Improvement Amendments) certified laboratory. Participants were notified that they had a genetic result by email and were given the option of receiving their results through their own medical provider or a study-provided geneticist/genetic counseling service by telephone. Educational materials about receiving a genetic diagnosis and their specific genetic condition were provided with a copy of the clinical genetic report prior to the result disclosure appointment. Participants provided feedback to the study team about the importance of receiving their results and satisfaction with the process.

Results: As of November 2018, we returned genetic results to 21 participants, including 20 parents with dependent children and 1 independent adult. Nineteen of the results were *de novo* and 2 were inherited from unaffected mothers. Six of the participants chose to receive the result through their own medical provider and 15 used the SPARK-provided geneticist or genetic counselor. On average, participants completed authorizations to receive results 8 days (SD= 16.0) after notification, and the 15 who received results through SPARK had appointments with the geneticist/genetic counselor 13 days (SD= 10.5) after completing their authorization. Participants indicated that they understood the next steps to take with their results and that they felt positively about having received a genetic cause for their child's autism and participating in SPARK.

Conclusions: We are able to return clinical genetic results using efficient, scalable processes. This is an effective way to engage participants and increase satisfaction with SPARK research participation. There are challenges to returning individual genetic results at scale, including but not limited to communication of inherited findings and ensuring that participants understand with the implications of the results.

55 **202.055** Routine Clinical Genetic Testing in Patients with Autism Spectrum Disorder and Related Developmental Disorders Has a Diagnostic Yield up to 40%, Improves Medical Management, and Significantly Alters Recurrence Risk Counseling

C. L. Martin*, K. E. Wain, T. Challman, L. Kasparson, S. M. Myers, E. Palen, J. Savatt, B. Finucane and D. H. Ledbetter, Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA*

Background: Genetic testing, via chromosomal microarray (CMA) for copy number variants (CNV) and whole exome sequencing (WES) for single gene sequence-level variants, has proven highly useful for identifying genetic etiologies of autism spectrum disorder (ASD) and other developmental brain disorders (DBD), such as intellectual disability and global developmental delay (ID/GDD). However, fewer than a third of U.S. children with DBD currently undergo recommended genetic testing (Kiely et al., 2016). In fact, a survey of child neurologists and developmental pediatricians found that 40% did not order genetic testing for children with ASD (Tchaconas et al., 2017).
Objectives: As part of our multidisciplinary autism and developmental medicine clinic, we have incorporated a genetics-first approach to routine care for all patients with ASD, ID/GDD, epilepsy, and/or congenital anomalies, including dysmorphic features. We report the diagnostic yield of clinical genetic testing in this patient population and the impact on medical management.

Methods: Patients were typically offered a testing cascade, starting with *FMR1* analysis for fragile X followed by CMA and WES. Single gene tests/panels were offered alternatively if there was a strong clinical suspicion for a particular disorder. We compared the diagnostic yield in patients with ASD only, ASD+ID/GDD, and ID/GDD without ASD.

Results: We used genetic cascade testing to evaluate 764 patients and identified a genetic diagnosis to explain their DBD in 159 (21%): 2% had fragile X syndrome, 14% had a pathogenic CNV, and 24% had a pathogenic single gene sequence variant(s). Since not all patients have completed WES testing yet, we used our initial dataset to estimate a combined diagnostic yield of up to ~40% if WES had been completed for all eligible patients. In the 159 patients with a genetic etiology, 15 (9%) had ASD only, 31 (19%) had ASD+ID/GDD, and 80 (50%) had ID/GDD without ASD, with the remaining including other testing indications. Identifying a genetic etiology has had important implications for medical management. For example, identifying a patient's 17q12 deletion informed the need to monitor for renal cysts/dysplasia and maturity-onset diabetes of the young. In addition, knowing a genetic etiology can significantly alter genetic counseling by providing more accurate recurrence risks. We identified a *de novo* pathogenic sequence variant in *SCN2A* which provided the family with a medical explanation for their child's ASD+ID diagnoses and, importantly, lowered their recurrence risk estimate from the ~10% quoted risk with one affected child down to the background population risk of ~1.5%. In another family, a maternally inherited 15q13.3 deletion was identified, resulting in a recurrence risk of 50%.

Conclusions: This genotype-first testing approach in a pediatric developmental medicine cohort illustrates the diagnostic power of genomic testing, as we can now provide a genetic etiology in up to 40% of patients, including a significant proportion who only had an ASD diagnosis. Given recent advances in WES, a single test can now be used to identify single gene variants and CNVs, providing an efficient testing mechanism for use in routine clinical care to provide vital information for medical management and family counseling.

56 **202.056** Sex Ratios in Autism, an Analysis of 8,167 Participants in the International Autism Mapping Project

B. M. Wieckowski[1], *E. Diamond*[2] *and J. M. Diamond*[3], *(1)Clinical psychology, The Wright Institute, Berkeley, CA, (2)The Wright Institute, Berkeley, CA, (3)Pediatrics, Kaiser Permanente Hospital, South San Francisco, CA*

Background: Estimates of autism spectrum disorder in the US are currently 1 in 59 children, with male to female ratios approximating 4:1. Autism spectrum disorder (ASD) includes a diversity of causal factors such as birth prematurity, Fragile X, single gene mutations, CNS infection and injury at birth. The reasons for the male predominance aren't clear. A more granular look at sex ratios may help.
Objectives: This study aimed to understand and characterize medical and genetic issues in children with a diagnosis of ASD, in an international sample of 8,167 children.

Methods: An archival dataset from the International Autism Mapping Project was examined. All parents who participated had a child with a confirmed diagnosis of autism born in the year 2000 or later and valid consent. This study nests within a larger study examining environmental factors in ASD. Within the environmental health questionnaire, parents were asked if their child had other genetic or medical diagnoses. Answers to that question were broken down into one of five categories, 1) single gene mutations, 2) multiple gene mutations, 3) known medical conditions or chromosomal disorders, 4) reported medical conditions or genetic conditions which lacked full specificity and 5) children who have multiple syndromes or conditions. Tables 1, 2, 3 include the number, gender, general inheritance pattern, and association to emotional-behavioral health. Sex ratios were examined, with X-linked conditions removed and treated separately.

Results: Of 8,167 records, 105 parents reported single gene mutations. The male to female ratio for this group is 2.62:1. Here, methylenetetrahydrofolate reductase (MTHFR) gene mutations were the most common genetic issue with 14 males and 8 females. Another frequent diagnosis was 22q11.2 deletion syndrome, with 15 males and 5 females. In the multiple gene mutation group, there were 52 children, with an overall male to female ratio of 3:1. In our 3rd grouping, of known medical conditions or chromosomal disorders, there are 177 children, with a general male to female ratio of 2.76:1. Here an unexpected finding involved Down syndrome, with 20 males and 4 females. Premature birth, defined as <32 weeks gestation, was reported for 27 children, with male to female ratio of 2.37:1. In our 4th grouping of 29 children, parents had reported issues not specific enough for full categorization; the male to female ratio for the group 3.83:1. In the 5th group, those with multiple conditions or syndromes, were 29 children, and here the male to female ratio is 4.6:1.

All tables will be presented.

Conclusions: The commonly reported sex ratio for children with autism is 4:1, with males predominating. In a more granular examination, this ratio varied considerably. Further, we found that in conditions thought to occur more or less equally between the sexes, the ratio was unexpectedly strongly biased towards males. Ratios were 3:1 in 22q11.2 deletion syndrome, 5:1 in Down syndrome, and 2.37:1 in prematurity. To what extent these striking asymmetries reflect bias in diagnosing ASD or sex-biasing genetic factors is unknown.

57 **202.057** The Differential Effect of Gene Dosage on Autism Risk and General Intelligence

Background:

Whole-genome analysis have estimated that rare mutations in over 1,000 genes may contribute to autism risk. Several studies have identified robust associations between rare Copy Number Variants *(CNVs)* and the diagnosis of Autism Spectrum Disorder (ASD). More specifically, a recent publication has shown that *de novo* mutations are associated with lower Intelligence Quotient (IQ) and a blunted autism profile. But almost nothing is known on cognitive and behavioral traits affected by rare CNVs and how these alterations lead to a diagnosis of autism.

We hypothesize that classes of mutations such as haploinsufficient ones versus duplications, have differential impacts on cognitive and behavioral traits, thus leading to a diagnosis of ASD by different mechanisms. To better understand the effect of CNVs, our laboratory recently developed models trained in the general population to estimate their effect size on non-verbal IQ (NVIQ) using constraint scores.

Objectives:

Understand the differential effect of haploinsufficiency and duplications on cognition, behavior and autism risk using autistic and general populations.

Methods:

We identified all CNVs ≥ 50Kb in 2,590 simplex ASD families in the Simon Simplex Collection and in 2,702 individuals from general population (Imagen and Saguenay Youth Study cohorts) following detection standard detection pipelines. We used statistical models integrating genomic and functional annotations (such as probability to be Loss of function Intolerant (pLI) score) to estimate the effects of deletions and duplications on autism risk and NVIQ.

Results:

We demonstrate that genome-wide deletions and duplications have a quantifiable effect on NVIQ and autism risk. Our model estimates that deletions and duplications decrease NVIQ respectively by 2.6 points per unit of pLI score (SE=0.42; P=7×10-10) and by 0.9 points per unit of pLI score (SE=0.29; P=2×10-3). This effect is identical in autistic and general populations for deletions but not for duplications.

We also show that deletions are significantly overrepresented in autistic probands compared to unaffected siblings or general population (both OR=1.3 per unit of pLI, 95%CI=[1.2;1.5], P=8×10-5). However, after adjusting for the effect on NVIQ, deletions are no more enriched in autism compared to general population. Conversely, duplications are significantly overrepresented in autism when comparing to unaffected siblings and general population (both OR=1.2 per unit of pLI, 95%CI=[1.1;1.4], P<4×10-5). This excess of duplications remains after NVIQ adjustment.

Conclusions:

Although deletions are highly overrepresented in individuals with a diagnosis of autism, it is probable that the general effect of haploinsufficiency is unrelated to core symptoms of ASD. Instead, our results suggest that haploinsufficiency increases the probability of clinical referral due to a pervasive impact on IQ. In contrast, the association between duplications and autism diagnosis is not explained by their effect on intelligence. To understand mechanisms underlying this association, we are investigating the effect of duplication on ASD severity, social responsiveness, and other measures of psychopathology. This study represents a new framework to study variants in ASD and better characterize the heterogeneity observed in clinic.

58 **202.058** The Prevalence of Autism Spectrum Disorder (ASD) and Attention Deficit Hyperactivity Disorder (ADHD) in Tuberous Sclerosis Complex (TSC). a Comparison of Prevalence in Patients with TSC1 and TSC2 Mutations.

W. Y. Cheung[1], *Y. Shen*[2], *C. Tye*[3], *F. S. McEwen*[4], *L. Underwood*[5], *E. L. Woodhouse*[6], *F. Sheerin*[7], *N. Higgins*[8], *H. L. Liang*[2,9], *E. Shephard*[10], *J. Yates*[11], *P. Background:

Tuberous Sclerosis Complex (TSC) is an autosomal genetic disorder caused by mutations in the TSC1 or TSC2 genes. Several reports indicate that compared with TSC2 mutations, TSC1 gene mutations present with less severe physical phenotype. However, although TSC is well established as a cause of ASD and ADHD, it is not known if the risk of ASD or ADHD also differs according to whether the TSC1 or TSC2 gene is mutated.

Objectives:

To determine the prevalence of ASD and ADHD based on mutation type (TSC1 or TSC2 gene) and to investigate the correlates of the psychopathological manifestations in TSC1 and TSC2 cases (e.g. tuber count, epilepsy severity etc).

Methods:

This study uses data from the TS2000 study, the first population based, longitudinal study of the natural history of TSC. 125 children aged 0-16 years diagnosed with TS were ascertained. Baseline measures of epilepsy severity, intellectual ability, cortical tuber count and genetic testing were undertaken. Participants were followed up and assessed using standardised and semi-standardised measures of ASD and ADHD. This include Autism Diagnostic Observation Scale (ADOS), Autism Diagnostic Interview- Revised (ADI-R) for ASD, Strength and Difficulties Questionnaires (SDQ), The Development and Well-Being Assessment (DAWBA), Diagnostic Interview for ADHD (DIVA) or Kiddie Schedule for Affective Disorders and Schizophrenia (KSADS) for ADHD.

Results:

1. a) Of the 125 participants, 19 had TSC1 mutations and 77 had TSC2 mutations.
2. b) 42.9% of patients with TSC2 mutation met stringent diagnostic criteria for ASD, a further 24.5% met criteria for probable ASD and

another 12.2% for more broadly defined ASD . Amongst patients with TSC1 mutations, 25% met stringent diagnostic criteria for ASD, 37.5% probable ASD and 18.8% met criteria for the more broadly defined autism spectrum disorder phenotype. The difference in prevalence between TSC1 and TSC2 cases was not statistically significant (p= 0.77).

3. c) Patients with TSC1 mutation had a slightly higher rate of definite ADHD diagnosis (27.3%) as compared to patients with TSC2 mutation (20.8%). A further 22.9% of participants with TSC2 mutation met criteria for probable ADHD as compared to 9.1% of TSC1 mutation cases. Again, the differences were not statistically significant (p=0.70).

Conclusions:

Mutations in both the TSC1 and TSC2 genes are associated with an increased risk of ASD and ADHD compared to the general population, but in this small sample, the prevalence of ASD and ADHD in TSC1 and TSC2 cases was not significantly different.

Poster Session
203 - Clinical trial design
5:30 PM - 7:00 PM - Room: 710

59 **203.059** Safety and Tolerability of GWP42006 (Cannabidivarin) in Subjects with Drug Resistant Epilepsy and Autism Spectrum Disorder

G. Barnes[1], *L. Sears*[2] *and J. Sullivan*[3], *(1)University of Louisville School of Medicine, Louisville, KY, (2)University of Louisville, Louisville, KY, (3)Pediatrics, University of Louisville, Louisville, KY*

Background: Epilepsy and autism have been estimated to coexist in 20-30% of patients with either disorder. The wide prevalence and association of these two disorders suggest common genetic factors and pathway correlations along with an increased predisposition for other pathologies. Lack of evidence-based recommendations for people afflicted by both these disorders suggest that insights into the common signaling systems of both disorders is needed. Phytocannabinoids may be a good class of compounds to search for modulators of both excitability and behavioral/cognitive phenotypes.

Objectives: To determine the safety and tolerability of GWP42005 (Cannabidivarin: CBDV) in autism and epilepsy subjects.

Methods: An expanded access protocol was developed via collaboration between the University of Louisville Autism Center and GW Pharmaceuticals. Although planned for 30-50 subjects, an initial pilot cohort of 5 subjects (ages 6-18 years) with documented autism and epilepsy was recruited. Autism spectrum disorder (ASD) was verified via Autism Diagnostic Observation Schedule (ADOS) testing and treatment resistant epilepsy (defined as 2 or more countable seizures per month) was verified via clinical history, initial 28-day seizure diary, and sleep eeg/polysomnogram. Clinical phenotyping by a senior psychologist and research team included seizure diary, actigraphy, Children's Sleep Habit Questionnaire, Children Behavioral Checklist, Vineland scales, Mean Length Utterance, Differential Ability Scales, Social Communication Questionnaire, ADOS Severity Score, Pervasive Developmental Disorder Behavioral Inventory (PDD-BI), and motor battery. Subjects were titrated from 1 mg/kg/day to 10mg/kg/day cannabidivarin (CBDV) (GWP42006; GW Pharmaceuticals) divided BID. Safety profiles for side effects, antiepileptic drug levels, liver function, basic metabolic panel, amylase/lipase, CBCs, ECG, and Columbia Suicide Scale were monitored.

Results: ADOS severity score was an average of 7 (range 4-10) and the baseline 2 week seizure frequency was 15 (range 2-50). Safety profiles of all 5 subjects suggest that CBDV is well tolerated at 10 mg/kg/day dosing through 44 weeks. No major laboratory abnormalities were noted. Gastroesophageal reflux, aggression, and sedation were the most common adverse events upon CBDV initiation and were likely related to elevated AED levels.We report seizure and cognitive/behavioral data at the 44 week time point when all 5 subjects were treated with 10 mg/kg/d CBDV. Three subjects with generalized epilepsy are seizure free. Caretakers of all subjects report consistent gains in social engagement and communication regardless of seizure frequency. Initial testing at 8 (6 mg/kg/d) and 24 weeks (10 mg/kg/day) suggest statistically significant reductions in the generalized seizure frequency (from 22 to 6 per 2 week epoch) at $p<0.0001$. Suggestions of impact on communication and core autism symptoms were documented by the increased Mean Length Utterance score, increased DAS nonverbal IQ, and a decreased ADOS-CSS ($p=0.09-0.18$).

Conclusions: The initial data suggest that CBDV 10 mg/kg is well tolerated and certainly has potential as an AED in the autism/epilepsy population. Interestingly, the initial cohort suggest CBDV may impact communication, social interactions, and core autism symptoms. Our current plan is to expand our cohort to all autism subpopulations and increase CBDV dosing up to 20 mg/kg/day in children 6 years of age and older.

60 **203.060** Efficacy and Safety of Bumetanide ORAL Liquid Formulation in Children and Adolescents with Autism Spectrum Disorder: Study Protocol of Two Randomised, Double-Blind, Placebo Controlled Phase III Trials

S. Kyaga[1], *V. Crutel*[2], *C. Albarran*[2], *Y. Ben-Ari*[3], *D. M. Ravel*[4] *and B. Falissard*[5], *(1)Servier Medical Affairs, Suresnes, France, (2)Institut de Recherches Internationales Servier, Suresnes, France, (3)Neurochlore, Marseille, France, (4)R&D, Neurochlore, Marseille, France, (5)Centre de Recherche en Epidemiologie et Santé des Populations, Paris, France*

Background:

Autism Spectrum Disorder (ASD) encompasses a heterogeneous set of neurodevelopmental conditions, characterized by core symptoms of abnormal social interactions with impaired communication abilities and repetitive or stereotypical behaviours. Although ASD can cause significant emotional and economic burden on people affected and their families, evidence-based treatment options are limited. Recent studies suggest that GABAergic neurons and circuits may be altered in ASD. Bumetanide is a loop diuretic which may reinstate GABAergic inhibition. A previous phase IIb study involving 88 children and adolescents (2-18 years) with ASD demonstrated a statistically significant improvement with bumetanide in the Childhood Autism Rating Scale (CARS) at day 90 compared to placebo. We here report the international clinical development for bumetanide in moderate to severe ASD, with two simultaneous similar phase III trials in two age subsets (2-7 years; 7-18 years).

Objectives:

The primary objective is to demonstrate the efficacy of bumetanide 0.5 mg (or 0.02 mg/kg for children with a weight<25 kg) twice daily as oral

liquid formulation compared to placebo on ASD core symptoms using the CARS-2 after 6 months of double-blind treatment.

Methods:

Both phase III trials are international, randomized, double-blind, placebo-controlled with a 6-month parallel-group design, followed by a 6-month open-label treatment period and a 6-week discontinuation period after treatment stop. Children and adolescents (N = 200 in each study, diagnosed according to DSM5 and fulfilling ADOS-2 and ADI-R criteria), with confirmed moderate or severe ASD (CARS-2 ≥ 34; CGI–S ≥ 4) will be randomised to bumetanide or placebo. An adaptation of the oral solution volume according to the weight of the patients will be performed at different pre-specified visits. The primary efficacy outcome measure is the CARS-2 total raw score at 6 months. Main secondary efficacy endpoints include individual CARS-2 domains, Social responsiveness Scale (SRS-2) total raw score, CGI-I and the Vineland Adaptative Behaviour Scale II. Efficacy endpoints will be expressed as changes from baseline to the 6-month visit and 12-month visit, respectively. Safety of bumetanide will be assessed throughout the study using adverse events recording, clinical examination, laboratory evaluation, ECG and renal ultrasound. Suicidality will be assessed using the Columbia-Suicide severity scale Children's version. A Data Monitoring Committee will be responsible for periodic review of patient's safety data. Pharmacokinetics measurements will be performed at several time points.

Bumetanide will be compared to placebo using a general linear model with baseline and stratification factors (country and gender) as covariates.

Results:

Recruitment was initiated in October 2018. The completion date of the two phase 3 trials will be in 2021/2022.

Conclusions:

This phase III program will provide further data on long-term efficacy and safety of bumetanide oral solution in children and adolescents with moderate to severe ASD. If positive, the outcome of these studies could contribute to the first available pharmacological treatment for core symptoms in ASD.

61 **203.061** Family Cognitive-Behavior Therapy for Psychoeducation in Multicenter, Aware and Care for My As Traits for High-Functioning Autism Spectrum Disorders in Adolescence: Study Protocol

Y. Iwama[1], *F. Oshima*[1], *W. Mandy*[2], *M. Hongo*[3], *M. Seto*[1], *Y. Hirano*[1], *C. Suto*[1], *M. Kuno*[1], *J. Takahashi*[1], *T. Ohtani*[3], *D. Matsuzawa*[1], *A. Nakagawa*[1] *and E. Shimizu*[1], *(1)Research Center for Child Mental Development Chiba University, Chiba, Japan, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Chiba University, Chiba, Japan*

Background: Adolescents with Autism Spectrum Disorder (ASD) are especially sensitive to stigma（Luisa, 2012). Generally, stigma is a barrier to gaining practical support（Wright et al., 2011; Yap et al., 2011) and psychoeducation for ASD, which works to counter effects of stigma, is important (Luisa, 2012). However, there are few approaches targeting psychoeducation on core ASD symptoms after childhood, many of which seek to treat various psychiatric disorders as co-morbidities in ASD (Sepúlveda, 2017; Sze, 2007). Gordon et al. (2015) showed that psychoeducation for ASD symptoms improved self-understanding and noticing of ASD symptoms, in both parents and children. We developed a psychoeducational program by using cognitive behavior therapy, Aware and Care for my AS Traits (ACAT) to adolescents with high-functioning ASD and their parents in Japan. Objectives: This study aimed to clarify whether ACAT can improve an adolescent's own understanding of their own ASD features and help improve their resilience for ASD.

Methods: The study was multi-centered and was conducted as a randomized controlled trial. Forty-eight adolescents, who were diagnosed with ASD, and their parents were recruited as participants through our research center's website. Twenty-four participants were assigned to the treatment as usual（TAU）group and the rest to the ACAT group. The ACAT group received a 100-minute session once a week for 6 consecutive weeks and one follow-up session in addition to regular medical care. The TAU group only continued regular medical care. In both the groups, effectiveness evaluation was conducted during pre-intervention, post-intervention, and follow-up session. The entire trial design is illustrated in Figure 1.

Results: This clinical trial is ongoing. Approximately 50% (23 pairs of patients) have participated until now, of which 15 have finished the trial. We will compare scores of measures between the two groups during the pre- and post–intervention. The primary outcome measure was the Autism Knowledge Questionnaire and the secondary outcome measures were Barriers to Access to Care Evaluation 3rd Edition, the Strengths and Difficulties Questionnaire, Vineland Adaptive Behavior Scales Second Edition, Parenting Resilience Elements Questionnaire, the General Health Questionnaire 12, Depression Self-Rating Scale for Children, and Electroencephalogram.

Conclusions: It is expected that participants of the ACAT group will significantly increase their self-understanding and noticing of for ASD symptoms compared to the TAU group. Additionally, it is expected that the ACAT group will improve in social adaptation and mental health significantly if children and parents can understand the characteristics of their own ASD features through their sessions. This intervention will contribute to the establishment of an effective treatment strategy based on evidence for adolescents with ASD.

Trial Registration：This clinical trial study registered on the UMIN Register No.000029851

62 **203.062** Feasibility and Design Challenges for a 10-Year Treatment Follow-up Study Examining the LONG-TERM Effects of EARLY Intensive Behavioral Intervention

L. Silverman[1], *E. Fischer*[2], *R. E. King*[1], *S. Iadarola*[1], *L. A. Oakes*[1], *M. Benham*[1] *and T. Smith*[1], *(1)University of Rochester Medical Center, Rochester, NY, (2)Developmental and Behavioral Pediatrics, University of Rochester Medical Center, Rochester, NY*

Background: In 2008 we conducted a novel, prospective study testing predictors of developmental outcome (IQ, adaptive behavior, ASD severity) after 12/24-months of early intensive behavioral intervention (EIBI) in a community-based sample of 71 children with ASD (age 20- 59 months). Predictors included social engagement and sensory-motor rituals. Generally, children with higher IQs had better outcomes. After controlling for age/ IQ/ EIBI site, social engagement but not sensory-motor rituals predicted IQ and adaptive functioning at exit. These data had implications for predicting short-term outcomes and better developmental trajectories in preschool. However, little is known about the long-term impact of EIBI, and whether early predictors continue to predict outcomes in adolescence (IACC, 2013). To address this gap, we conducted a 10-year longitudinal follow-up study designed to evaluate and compare the outcomes of children who originally received EIBI versus treatment as usual (TAU).

Objectives: 1) Report the feasibility of a 10-year follow-up study that was not planned a priori; and 2) Discuss the unique design challenges and experimental decisions that were made to help guide future research. We will address recruitment challenges, selection of assessment measures, and unique features of test administration.

Methods: From the initial pool of 136 participants (71 EIBI, 65 TAU), 110 met eligibility criteria for the 10-year follow-up study, at age 14-18 years. Recruitment letters were mailed; some participants did not have valid contact information and did not return calls (invalid numbers or 'lost to follow up'). Additional recruitment methods were utilized (social media, flyers, last letter, data pull from EMR). Enrolled participants completed measures of cognitive ability, academic achievement, language proficiency, and autism diagnostic status. These included adolescent measures, parent-report measures, and teacher-report measures. Enrollment is ongoing until June 2019.

Results: To date, thirty-eight of the original 70 EIBI participants, and 22 of the original 65 TAU participants enrolled in the study (see CONSORT diagram). Feasibility outcomes: so far, we met goals and recruited approximately 54% (EIBI) and 34% (TAU). Recruitment barriers were addressed using a wide range of strategies, including letters, flyers, social media, and word of mouth. We conducted assessments in the home to minimize transportation barriers, and scheduled visits during vacations that brought participants to our region. Assessments were selected to maximize the validity of comparisons to our original study, without overwhelming participants.

Conclusions: A 10-year follow-up study can provide important information about long-term treatment outcomes. In the literature on follow-up studies in the US, re-enrollment rates are highly variable; with many studies reporting percentages in the low sixties to low eighties. Although we are still enrolling, our current rates may reflect inherent challenges for parents and children with ASD, who are reported to have more stressors and daily hassles than parents of other populations. To promote successful longitudinal studies, specific methodological challenges must be addressed proactively (e.g., recruitment, visit accessibility, selection of measures). Lessons learned from the current study can help to guide future researchers in preparing proactively for design challenges that may arise

63 **203.063** Preliminary Results of Therapeutic Potential of Multiple Sessional Intermittent Theta Burst Stimulation over the Bilateral Posterior Superior Temporal Sulci in Children and Adolescents with Autism Spectrum Disorder

H. C. Ni[1], *H. Y. Lin*[2] *and Y. Z. Huang*[3], *(1)Psychiatry, Chang Gung Memorial Hospital at Linkou, Taipei, TAIWAN, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan, (3)Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan*

Background:

Accumulating studies have demonstrated the therapeutic potential of the repetitive trans-cranial magnetic stimulation (rTMS) on improving the core symptoms of autism spectrum disorder (ASD). However, the accurate and consistent stimulation targets and protocols remained elusive.

The posterior superior temporal sulcus (pSTS) is an important brain region for the social brain network and theory of mind. Further, several studies have demonstrated the abnormal activation of pSTS in ASD. Therefore, pSTS may serve as another potential therapeutic target of rTMS in ASD.

Theta-burst stimulation (TBS) is a modified rTMS and is capable of producing excitatory or inhibitory aftereffects on cortical excitability as traditional rTMS. Moreover, TBS is more advantageous than the traditional TMS in being more efficient to produce the similar after-effects in a much shorter duration with fewer total stimulus pulses at lower stimulus intensity. TBS is considered more implementable in the clinical practice.

Objectives:

The aim of this study is to investigate the therapeutic impacts of intermittent TBS (iTBS) to the bilateral posterior superior temporal sulci (pSTS) in children and adolescents with ASD.

Methods:

The study was implemented as an randomized, double-blinded, sham-controlled and parallel trial. 80 children and adolescents with ASD were randomly assigned to the pSTS or sham-control group. In phase 1, the participants received either iTBS or sham stimulations twice per week for 4 weeks. In phase 2, after completing the first 4-week interventions in phase 1, all of the participants were invited to receive real iTBS twice per week for another 4 weeks. After completing phase 2, all of the participants will be followed up 4 weeks later. We measured the clinical symptoms and neuropsychological functions at baseline, at 4 weeks (post 4w, phase 1), 8weeks (post 8w, phase 2) and 12weeks (post 12w, follow-up). The clinical symptoms were measured with the Autism Spectrum Quotient (AQ), the Social Responsiveness Scale (SRS) and the Repetitive Behavior Scale-Revised (RBS-R) as rated by parents, respectively. The neuropsychological functions were assessed with the Frith-Happe animations and Eye tasks.

Results:

Hitherto, there were 74 participants enrolled in the trial. 5 participants were excluded from this study because of personal reasons (n=2), somatic discomforts (dizziness and insomnia, n=2) and abnormal MRI findings (brain tumor, n=1). Overall, the preliminary analyses showed trend-level decreases in total scores of the AQ, SRS and RBS-R at post 4w and post 8w in the pSTS group. The improvement was more obvious in post 8w than post 4w and persisted at post 12w. Among the clinical symptoms, the improvement in the social communication domain was most obvious. Preliminary analysis revealed that the improvement was not associated or mediated by intelligence, gender or age. As for the results in the neuropsychological functions, the interpretation of social intention during the Frith-Happe animations task improved in the pSTS group at post 4w.

Conclusions:

Our preliminary results suggest that the bilateral pSTS may be a potential therapeutic target of rTMS in ASD, especially for improvement in social function. Besides, the therapeutic effects may be more prominent with longer duration of interventions.

64 **203.064** The Landscape for Recruitment of Pre-School Aged Children with Neurodevelopmental Conditions in Scotland.

E. J. Hutton[1], *L. Millar*[2], *P. Rowe*[3] *and J. Delafield-Butt*[1], *(1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)Faculty of Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom*

Background: Recruitment of children with neurodevelopmental conditions presents a challenge in research. Many caregivers, educators and clinicians can be protective and have excessive time demands. This can create barriers to recruitment. In Scotland, despite a unified health service ethics system and complementary university ethics board, many local approval processes are additionally required. Different processes with different values and expectations are required, and these are not readily apparent.

Objectives: We sought to determine the most efficient recruitment pathways for children with neurodevelopmental conditions to aid the development of recruitment strategies in future research in Scotland.

Methods: This work is part of a Phase III diagnostic trial to assess the sensitivity of iPad games to detect autism spectrum disorder in preschool aged children (Clinical trials Gov. ID NCT03438994). Groups included: typically developing (TD), diagnosis of autism spectrum disorder (ASD) and diagnosis of another neurodevelopmental condition that is not autism (OND). Each health board, clinician, local authority, nursery, and educational team lead approached was recorded and approval rate calculated. For those approved, the number of information packs distributed was noted by pathway (NHS health board, local authority council, or private nursery) and site. Returned consent forms and final participant participation was recorded. These data were stratified by pathway and local authority within each pathway.

Results: 5 NHS health boards, 10 local authorities and 14 private nurseries were approached for approval; of which, 3, 6 and 13, respectively, gave approval. Percentage return was best in private nurseries (37%), however was limited to TD participants. Results demonstrated that the council pathway yielded the highest number of participants across all groups (171). Stratified by pathway, NHS yielded 17 ASD from 10 sites; local authority yielded 112 TD, 16 OND and 43 ASD from 17 sites and private yielded 159 TD from 13 sites. In all cases the number of consent forms returned matched the number of assessments which took place.

Conclusions: These results indicate that successful recruitment is more likely to occur via local council pathways. Although the return of participants was low in comparison to the number of information packs distributed, this may be due to the high volume of packs distributed in this pathway. The high percentage return from private nurseries is likely due to good relationships between staff and parents. The lowest return was observed in the NHS pathway, this may be due to high time pressures on clinicians, leaving them unable to dedicate time to research or time to the clinical assessment pathway for neurodevelopmental conditions. Until pressure on clinicians is lifted and local health boards develop a unified method for assessment and treatment of children, recruitment in NHS facilities will remain an undesirable option for research studies. While local authority and private nurseries remain the most effective route to recruitment, development of effective strategies is hindered by the lack of transparency and over complication of differing values between local authorities, nurseries, and schools. A consistent, cohesive application process within the NHS and local authority pathways would be of great benefit.

65 **204.065** Initial Severity of Autism Symptoms Moderates the Effect of Intensity on Expressive Communication in Children with ASD

P. Yoder[1], *Z. Warren*[2], *S. Rogers*[3], *A. Estes*[4], *G. Hellemann*[5] *and J. Munson*[6], *(1)Department of Special Education, Vanderbilt University, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)University of Washington, Seattle, WA, (5)UCLA, Los Angeles, CA, (6)UW Autism Center, University of Washington, Seattle, WA*

Background:

When intensity levels have been compared in other populations, differences between two intensity levels of the same treatment tended to vary by characteristics of the children prior to treatment (i.e., moderators).

Objectives:

To determine whether initial severity of autism moderates the effect of intensity of treatment on expressive communication.

Methods:

The measure of expressive communication was derived from 12 monthly six-minute semi-structured communication samples administered by an examiner who was blind to intensity group assignment using toys not used in the treatment sessions. These sessions were coded by an observer who was blind to intensity group using a timed event sampling method. The metric from this procedure was the weighted frequency of intentional communication. Weights varying from 1 to 3 were assigned for nonverbal, single word, and multi-word communication acts, respectively. The measure of ASD severity was the calibrated severity score from the ADOS.

The mixed level model of growth in expressive communication was described by Dr. Rogers. Slope was used as the parameter of interest.

Results:

Time was centered at study entry; thus, intercept could be interpreted at level at study entry. There were a nonsignificant interaction between ASD severity and Intensity Group on the intercept. There was significant gain in weighted frequency of intentional communication in both intensity-level groups, but no main effect of intensity level.

There was an interaction between autism severity and intensity level on weighted frequency of intentional communication growth rate (pseudo R square change = .07; Cohen's *d* = .55) with higher intensity affecting communication more than lower intensity in the mildly affected children only (CCS 3 – 7).

Conclusions:

This is the first study to show that intensity of treatment affects only mild to moderately affected children with ASD. This is analogous to a finding Dr. Rogers reported on: the least affected children benefited from more hours of treatment per week. Additionally, this study showed that a particular method of briefly assessing communication called individual growth and development index (IGDI, Carta, Greenwood, Walker, & Buzhardt, 2010) is sensitive to treatment effects (a type of validity).

66 **204.066** The Effects of Pivotal Response Training on Reciprocal Vocal Contingency in Children with Autism Spectrum Disorder

P. Yoder[1], *J. McDaniel*[1], *M. Crandall*[1], *M. E. Millan*[2], *C. Ardel*[2], *G. W. Gengoux*[2] *and A. Y. Hardan*[3], *(1)Department of Special Education, Vanderbilt University, Nashville, TN, (2)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (3)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background: Pivotal response treatment (PRT) is a naturalistic developmental behavioral intervention for children with autism spectrum disorder (ASD) that targets "pivotal" skills (e.g., motivation and responsivity) to facilitate broad changes across functional skills. Combining clinician-delivered and parent-implemented pivotal response training as a package treatment (PRT-P) may increase the program's effectiveness for children with autism spectrum disorder (ASD). Reciprocal vocal contingency (RVC), an automated measure of vocal reciprocity, may provide more internally-valid evidence of the effects of PRT-P relative to parent report and parent-child interaction session measures, which are at risk for over-estimating children's skills in the PRT-P group relative to the control group. Due to its automatic derivation, RVC is at low risk of bias and feasible for clinical use. Additionally, RVC is designed to be independent of chance sequencing of events. The more frequently children and adults vocalize, the more their vocalizations will be adjacent by chance. In children with ASD, past studies have shown that RVC continues to be construct valid as a measure of reciprocity, even after controlling for base rates of child and adult vocalizations. In contrast, its primary competitor as a putative measure of "vocal reciprocity" (i.e., number or rate of vocal turn-taking) ceases to show convergent validity after controlling for the base rates of child and adult vocalizations.

Objectives: To examine whether participants in the PRT-P group have higher ranked RVC values than participants in the control group after 12 and 24 weeks of intervention.

Methods: Forty-eight children with ASD (29 to 71 months old) were randomly assigned to either the PRT-P or business as usual control group. Data for the current analysis were available for 40 participants. The PRT-P included weekly individual parent training sessions and 10 hours per week of in-home intervention for 12 weeks, followed by 12 additional weeks of monthly parent training sessions and 5 hours per week of in-home intervention. For each participant at each of three measurement periods (pre, mid-intervention phase, and posttest, separated by 12 weeks each), we quantified RVC from two daylong vocal samples using a computer program to organize the data for subsequent three-event sequential analyses that calculated the degree to which children responded to adult vocal responses to children's immediately preceding vocalizations.

Results: Although the group differences were non-significant at baseline (Time 1; p = .12) and after 12 weeks of intervention (Time 2; p = .25), children in the PRT-P group had higher ranked RVC scores than children in the control group after 24 weeks of intervention (Time 3; U = 125, p = .048). The percentage of all possible pairwise comparisons for which the PRT-P group exceeded the control group was 69%, which is a moderate effect size.

Conclusions: These findings support the effectiveness of PRT-P on vocal reciprocity of children with ASD, which may be a pivotal skill for language development. Continued investigation is required to determine the specific time range and developmental level for which RVC is most useful.

67 **204.067** Objective Measurement of Initiations to Peers Following Behavioral Social Skills Treatment

G. W. Gengoux[1], *J. Hopkins*[2], *A. A. Ruiz*[2], *M. E. Millan*[1], *R. K. Schuck*[1], *Y. Weng*[3], *J. Long*[3] *and A. Y. Hardan*[4], *(1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)Palo Alto University, Palo Alto, CA, (3)Stanford University School of Medicine, Stanford, CA, (4)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background: Studies of children with Autism Spectrum Disorder (ASD) have repeatedly documented low rates of initiations especially to peers, even among children without intellectual disability. Young children typically start peer interactions either 1) by making requests or 2) by initiating to share a social experience. Children with ASD often struggle with both types of initiations. Given that requesting often results in greater tangible reinforcement in natural environments, it is hypothesized that systematic teaching of requesting could motivate children to initiate for social purposes (i.e., sharing social experiences).

Objectives: This presentation reviews data from a randomized controlled trial of a social group intervention aimed at motivating children with ASD to initiate by systematically teaching and reinforcing requesting. Video recorded observations of free play with peers are used to evaluate changes in initiation frequency and type.

Methods: Participants included 44 children with ASD from 4-6 years old. Participants were randomly assigned to the Social Initiation Motivation Intervention (SIMI; n=22) or control group (n=22). Participants in the SIMI condition received 8 weekly 75-minute social group sessions with typically-developing peers, during which therapists arranged cooperative activities to teach and reinforce initiations to request items from peers. Participants in the control group continued stable community-based services. Trained raters blinded to treatment assignment and time point scored video recordings of free play with peers. Frequency of requests to peers were recorded and provided evidence of progress with skills directly targeted in treatment, while frequency of joint attention and social interaction initiations provided evidence of generalization to other initiation types.

Results: Following the 8-week treatment, children in the SIMI intervention showed enhanced motivation to initiate to peers. Not only did they show greater improvement than controls in initiating to make requests during videotaped free play interactions (p = 0.029), they also showed greater generalization to other types of spontaneous social initiations compared to controls (p = 0.007). Results also indicated greater improvement on measures of global social functioning, including the Clinical Global Impressions-Improvement Scale (CGI-I; p=0.026) and Vineland-II Socialization scale (p=0.049).

Conclusions: Findings suggest that behavioral treatment focused on teaching initiations shows promise for enhancing social motivation in children with ASD and improving broader aspects of social functioning. Objective rating of treatment response and generalization can be obtained from review of video recorded interactions with peers. Implications for design of effective inclusive social skills programming and remediation of core social deficits in ASD will be discussed.

68 **204.068** The Sensory Domain As a Target for Treatment in ASD Clinical Trials: Electrophysiological and Behavioral Markers of Therapeutic Change

P. M. Siper[1], *T. Tavassoli*[2] *and A. Kolevzon*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background: Sensory symptoms represent a core feature of autism spectrum disorder (ASD) and a novel domain to target in clinical trials.
Objectives: This study piloted the utility of electrophysiological and behavioral measures for assessing change in sensory reactivity during a clinical trial of insulin-like growth factor-1 (IGF-1) in children with Phelan-McDermid syndrome (PMS). PMS is one of the most common single-gene causes of ASD and sensory hyporeactivity is a prominent feature of the syndrome.

Methods: Participants included six children with PMS 5-12 years of age enrolled in an ongoing placebo-controlled, double-blind, crossover design study. Transient visual evoked potentials (VEPs) and the Sensory Assessment for Neurodevelopmental Disorders (SAND) were collected at baseline and week 12 of each study phase of the crossover. VEPs reflect the sum of excitatory and inhibitory postsynaptic potentials and provide a window into the brain to examine excitatory/inhibitory balance. The magnitude squared coherence statistic (MSC) was used to examine coherence of high-frequency oscillatory responses. The SAND is a clinician-administered observation and corresponding caregiver interview that quantifies sensory reactivity according to DSM-5 criteria for ASD (hyporeactivity, hyperreactivity, seeking).

Results: There was a significant increase in low gamma (30-36 Hz) activity following IGF-1 relative to baseline (p=.048). Notably, MSC increased in 5 of 6 patients. Significant clinical improvement was observed on the SAND Hyporeactivity Domain following IGF-1 treatment (p=.037).

Conclusions: Data collection is ongoing and preliminary results suggest that VEPs and the SAND represent two novel outcome measures for use in clinical trials for individuals with ASD and related conditions.

69 **204.069** Using fMRI to Identify Neural Mechanisms of Response to Cognitive Behavioral Therapy for Anxiety in ASD

D. G. Sukhodolsky[1], *K. Ibrahim*[1], *C. Kalvin*[2], *J. Eilbott*[1] *and K. A. Pelphrey*[3], *(1)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Child Study Center, Yale University, New Haven, CT, (3)University of Virginia, Charlottesville, VA*

Background: Cognitive Behavioral Therapy (CBT) can be helpful for anxiety in ASD but, little is known about the neural mechanisms of this potentially effective intervention.
Objectives: This presentation discusses a randomized-controlled trial to identify neural mechanisms of CBT efficacy for anxiety treatment in children with ASD, and to present the results of an open study of fMRI correlates of emotion regulation before and after CBT for anxiety in ASD.

Methods: Our ongoing, randomized-controlled study has been designed to test the effects of CBT on the fMRI signatures of fear processing and emotion regulation in children with ASD. Children are randomized to CBT conducted using the CBT manual or to a supportive therapy control condition and anxiety outcomes are assessed by the Pediatric Anxiety Rating Scale administered by an independent evaluator. Children also complete neurocognitive tasks of emotion regulation and socio-emotional processing before and after treatment. Prior to initiating the randomized trial, we also conducted an open study with 10 children with ASD (age rage 10 to 12; 3 girls, 7 boys) who completed the face perception and emotion regulation tasks during fMRI before and after CBT for anxiety. During the fMRI tasks children were required to view faces and shapes and to either passively look at the emotional or neutral images or to decrease their emotional response to aversive emotional images.

Results: A whole-brain fMRI analysis of the emotion regulation task revealed *increased activation* in vmPFC, vlPFC, and dlPFC after CBT. We also observed *reduction of left amygdala* and bilateral insula activation in the look-negative vs. look-neutral contrast (emotional reactivity) after treatment. The magnitude of the effects of CBT on the levels of BOLD activation in the contrasts of interest calculated as the Cohen's *d* effect size for the difference in post- to pre-treatment activation divided by the pooled standard deviation ranged from 0.68 to 1.23, indicating moderate to large effect sizes. Mean differences between faces vs shapes condition of the face perception task were computed from beta values extracted from the structurally defined left and right amygdala and vmPFC for the pre- and post-treatment scans. Paired-samples t-test indicated that there was a decrease in activity in the bilateral amygdala (Cohen's d=0.66 and 0.51 for left and right amygdala, respectively) and an increase in activity in the vmPFC (Cohen's d=0.51) relative to baseline.

Conclusions: CBT can engage the neural circuitry of emotion regulation in children with ASD and co-occurring anxiety. Clinical implications of understanding neural mechanisms to enhance the effectiveness of CBT for anxiety symptoms in ASD are discussed.

70 **204.070** Using the Boscc As Primary Outcome of the German A-FFIP Multicenter RCT

J. Kitzerow[1], *S. Kleber*[2], *Z. Kim*[3], *K. Teufel*[3] *and C. Freitag*[3], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Autism Research and, Frankfurt am Main, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frakfurt am Main, Germany, (3)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany*

Background: The *Frankfurt Early Intervention Program for preschool children with ASD (A-FFIP)*is a manualized low-intensive therapist-delivered and parent-supported early intervention program, which is currently studied for efficacy by a German multi-center randomized controlled trial (target sample N = 134 preschool-aged children at four study sites). The primary outcome measure is the *Brief Observation of Social Communication Change*(*BOSCC*). Several additional secondary outcome measures as well as mediating mechanisms are studied.
Objectives: To (1) present data on the feasibility to standardize the BOSCC assessment with an independent professional at the different study sites; (2) explore concordance of BOSCC (Version December 2017) results based on video-based coding of differently structured interaction scenes; (3) explore concurrent validity with the ADOS-2 based comparison score and ESCS based joint attention measures.

Methods: Cross-sectional data of N = 15 children, aged 2-5.5 years old are reported.

(1) Feasibility questionnaires were completed by all BOSCC-testers and descriptive data are reported. (2) The BOSCC coding system was applied to 4 different 12-minute video scenes: BOSCC, ADOS-2, DCMA, and ESCS. Mean scores were compared by rANOVA. (3) Pairwise correlation of BOSCC, ADOS-2, and ESCS derived measures was calculated.

Results: The BOSCC implementation was highly feasible; still, some errors had to be corrected during the training phase. BOSCC coding results did not differ by the structure of the scene or interaction. Similar to previous studies, medium correlations of BOSCC and ADOS-2 scores were replicated and medium to high correlations of BOSCC and different ESCS joint attention measures were found.

Conclusions: The BOSCC is a feasible and promising outcome measure to study change in core ASD symptoms in preschool aged children, which can be rated by blinded raters from different video scenes and also allows the re-coding of existing video-based material. The implementation of the BOSCC in several early intervention studies will allow a direct comparison of effect sizes between studies. The final analyses will include a

larger sample.

71 **204.071** A Lifespan Approach to Patient-Reported Outcomes and Quality of Life for Autism Using Nih Promis®

L. Graham Holmes[1], *C. J. Zampella*[2], *C. C. Clements*[1], *B. B. Maddox*[1], *J. McCleery*[3], *J. Parish-Morris*[1], *R. T. Schultz*[1] *and J. S. Miller*[2], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:

Patient-reported outcomes (PRO) and quality of life (QoL) are subjective patient perspectives of everyday functioning and subjective well-being (SWB). Incorporating PRO measures with clinical data can inform research, healthcare delivery, and policy. The utility of these constructs is limited for autism due to lack of well-validated, widely available, and comprehensive yet feasible measures. To address this gap, we curated a National Institutes of Health PROMIS® Autism Battery (PAB) for children, teens, and adults. PROMIS® item banks (4-8 items each) cover physical (e.g., sleep), mental (e.g., emotional distress), social (e.g., social support, social isolation) and global health. The results of our survey of people with autism and their families illustrate both the utility of PROMIS® and how lifespan QoL and functioning in autism compare to the general population.

Objectives:

(1) Describe the development and validation of the PAB.

(2) Compare PAB scores for children (parent report), teens (parent and self-report), and adults (self-report) with autism to the general population.

(3) Examine gender differences across the life course.

(4) Examine age effects for young, middle, and older adults with autism.

Methods:

Participants had a medical diagnosis of autism and were recruited via Interactive Autism Network and other research registries. Parents of children (ages 5-13, *n*=211, 77% male), parents of teens (ages 14-17, *n*=246, 69% male), teens (*n*=141, 71% male), and adults (ages 18–65, *n*=227, 47% male) completed an online survey about health and QoL. A subset (*n*=62) completed qualitative follow-up interviews. In the parent datasets, half of children and one-third of teens were reported as functioning below grade level. T-tests and ANOVAs were used for norm, gender, and age comparisons, α=.01.

Results:

(1) Participants rated the PAB as feasible and acceptable and provided suggestions for improvements.

(2) Statistically significant symptom elevations were reported for children (all domains), for teens (all domains except anger, *p*=.025), for teen self-report (all domains except anger and family relationships, *p*'s>.243), and adults (See Tables).

(3) No gender differences were reported for children, or via teen self-report. Compared to boys, parents reported that teen girls were more stressed (*p*=.008), anxious (*p*<.001), and had poorer sleep (*p*'s<.009). Compared to adult men, women reported more symptoms in global health (*p*=.008), sleep disturbance (*p*=.001), social isolation (*p*=.009), and lower self-efficacy (*p*=.003).

(4) Middle and older adults reported more symptoms than young adults for sleep issues (*p's*<.008), social issues (*p's*<.001), anger (*p*=.001), and subjective well-being (*p's*<.001).

Conclusions:

Ideally, interventions and services are designed such that they have measurable, positive impacts on health, well-being, and/or QoL. The current findings indicate that a battery of PROMIS® measures for these constructs was both acceptable and effective for quantifying these domains for children, teens, and adults with autism and their families. Furthermore, the current results indicate impairments in relationships, physical and mental health, and well-being in children, teens, and adults with ASD, with adults also reporting poorer functioning and increased social isolation with age. Using these measures as part of research and routine care may help prioritize high-impact services and improve service delivery across the life course.

72 **204.072** Effects rTMS-Based Neuromodulation Dosage on Event-Related Potentials and Evoked and Induced Gamma Oscillations in Children with Autism Spectrum Disorder

M. Casanova[1], *E. M. Sokhadze*[2], *E. V. Lamina*[3], *E. L. Casanova*[4] *and D. P. Kelly*[5], *(1)University of South Carolina School of Medicine, Greenville, SC, (2)University of Louisville, Louisville, KY, (3)Biomedical Sciences, UNIVERSITY OF SOUTH CAROLINA SCHOOL OF MEDICINE GREENVILLE, Greenville, SC, (4)University of South Carolina, School of Medicine, Greenville, SC, (5)University of South Carolina School of Medicine Greenville, Greenville, SC*

Background: Autism is defined as a spectrum of behavioral disorders that have in-common impairments in social interaction and communication skills, language deficits, and a restricted repertoire of interests and stereotyped activities. There are several theoretical models of the neuropathology of autism spectrum disorders (ASD), and one of them suggests the presence of an excessive cortical excitation/inhibition (E/I) ratio that affects functional connectivity. This model explains atypical event-related potential (ERP) and evoked and induced gamma oscillations observed in ASD during task performance. Repetitive transcranial magnetic stimulation (rTMS), especially using low frequency inhibitory stimulation, can be considered as a method of modulating the E/I bias.

Objectives: In our prior exploratory studies we used different schedules of rTMS to investigate outcomes of rTMS in ASD. In this study, 124 high functioning ASD children (IQ>80, <18 years of age) were recruited and assigned to either a waitlist group or one of three different number of weekly rTMS sessions (i.e., 6, 12, 18) to investigate effects of dosage on functional and behavioral outcomes. The project was aimed at selection of more effective length of rTMS course.

Methods: TMS consisted of trains of 1.0 Hz pulses applied over dorsolateral prefrontal cortex. The experimental task was a three-stimulus visual oddball with illusory Kanizsa figures. Behavioral response variables included reaction time and error rate along with EEG indices such as ERP and evoked and induced gamma oscillations. One hundred and twelve patients completed the assigned number of rTMS sessions.

Results: We found significant positive changes from baseline to post-TMS treatment period in motor responses accuracy (lower percentage of

committed errors, restored normative post-error slowing), in ERP indices and in evoked and induced gamma responses. Parental reports showed significant reductions in aberrant behavior scores as well as decreased scores of repetitive and stereotypic behaviors. The gains of outcomes increased with the total number of treatment sessions. Behavioral questionnaires (ABC,RBS-R, SRS-2) showed significant improvements in ratings of autism symptoms both post 12- and 18-session rTMS course.

Results of our clinical research study showed most significant changes from baseline in functional measures of performance in oddball task and in behavioral symptom ratings following 18 sessions of rTMS treatment. Several measures showed a difference from baseline and waitlist in reaction time and ERP/EEG variables after 12 sessions of rTMS, but only a few of them reached statistical significance post-6 session rTMS course.

Conclusions: Our results suggest that rTMS, particularly after 18 sessions, facilitates cognitive control, attention and target stimuli recognition by improving discrimination between task-relevant and task-irrelevant illusory figures in an oddball test. Improvement in executive functions and behavioral symptoms of autism further suggests that TMS has the potential to target core features of ASD. The results of this dosage-response study could serve as important pre-requisites that could inform the planning of a blinded randomized clinical trial. Among potential implications of the study should be considered potential of combining rTMS with neurofeedback training aimed at reinforcement of neuromodulation effects using operant conditioning.

73 **204.073** Psychometric Properties of a Novel Vineland-II™ 2-Domain Composite Score to Assess Social Communication and Social Interaction in Autism Spectrum Disorder

G. Dawson[1], *T. Willgoss*[2], *S. Le Scouiller*[2], *L. Squassante*[3], *K. Sanders*[4], *J. W. Smith*[2], *F. Bolognani*[3] *and R. L. Findling*[5], *(1)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (2)F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom, (3)F. Hoffmann-La Roche Ltd., Basel, Switzerland, (4)Product Development Neuroscience, F. Hoffmann-La Roche Ltd., Basel, Switzerland, (5)John Hopkins Children's Center, Baltimore, MD*

Background: Challenges in socialization and communication are core symptoms of autism spectrum disorder (ASD) and need to be addressed by new treatments for ASD. However, there is a lack of consensus on appropriate outcome measures for evaluating core symptoms of ASD in clinical trials of new treatments.
Objectives: The Vineland Adaptive Behavior Scales, Second Edition (Vineland™-II) Socialization and Communication domain scores are both reliable and valid scales used as endpoints in ASD clinical trials. To explore the measurement properties of a novel Vineland-II 2-domain composite (2DC) score, which combines these 2 independently validated scales, we conducted a psychometric analysis of this new scale using data from the VANILLA phase 2 trial of balovaptan, a 12-week study in adult males with ASD and intelligence quotient (IQ) ≥ 70 (NCT01793441).

Methods: The Vineland-II 2DC score is calculated as the arithmetic mean of the Vineland-II Socialization and Communication domain standard scores. The measure was administered by experienced raters. Test-retest reliability was assessed using interclass correlation coefficient (ICC) in patients with no change in their clinical status at day 84 on the Clinical Global Impression–Improvement (CGI-I) scale. Sensitivity to change (baseline to day 84) was assessed by comparing mean scores on Vineland-II 2DC between subjects with CGI-I scores of "minimally improved" or better versus "no change" or worse using analysis of covariance. Convergent and discriminant validity, as well as known-group validity, were also explored with baseline Vineland-II 2DC, age, and IQ as covariates.

Results: The Vineland-II 2DC demonstrated very good test-retest reliability with an ICC of 0.83 (N = 88). The 2DC score correlated with (0.97 Pearson correlation coefficient) and demonstrated similarly robust psychometric properties to the Vineland-II Adaptive Behavior Composite score. Correlations with symptom-oriented scales that measure attributes different to those measured by Vineland-II 2DC were weak, as hypothesized. Known-group validity was strong, with significant difference in scores between Clinical Global Impression–Severity groups (nominal $P < 0.05$); and sensitivity to change for the Vineland-II 2DC score was significant across groups (nominal $P < 0.05$).

Conclusions: Challenges in socialization and communication are among the most important symptoms that need to be addressed by new treatments for ASD. However, there is a lack of validated measures of these core symptoms established in ASD clinical trials. In adults with ASD and IQ ≥ 70, the novel Vineland-II 2DC score shows evidence of reliability, validity and sensitivity to change, and enables a comprehensive assessment of socialization and communication abilities in people with ASD. These findings support the use of the Vineland-II 2DC score as an outcome measure for assessing the core deficits of socialization and communication in future ASD phase 3 clinical trials. Replication of these findings in other datasets is required to further validate the Vineland-II 2DC score.

74 **204.074** Significant Increase in Power in Clinical Trials with Use of the Newly Available Vineland-3 Growth Scale Values

C. Farmer[1], *A. Thurm*[1] *and J. S. Miller*[2], *(1)National Institute of Mental Health, Bethesda, MD, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Although adaptive behavior is relevant due to its clinical significance, it is used rarely as a primary outcome measure in clinical trials. This may be because adaptive behavior scores are often expressed as scaled or standard scores. Scaled scores, which provide information about a child relative to their peers, may remain unchanged even as a child's ability level increases or decreases. Further, scaled scores may decrease even if ability increases, if the rate is slower than chronological-age expectations. Thus, studies adequately powered to detect changes in scaled scored require relatively large and potentially unobtainable sample sizes. The third edition of the Vineland Adaptive Behavior Scales (VABS-3) includes growth scale values (GSV), which are an index of ability derived through item response theory. GSV quantities change within individuals, including small changes. Given its recent publication, the VABS-3 GSV should be explored as a potential outcome measure in studies of neurodevelopmental disorders.
Objectives: The goal of this study was to demonstrate the advantage of VABS-3 GSV for use as an outcome measure in clinical trials of neurodevelopmental disorders. Using data from an ongoing natural history study of creatine transporter deficiency (a rare, X-linked, metabolic condition associated with autism spectrum disorder and other neurodevelopmental disorders), we quantified change over 6 months in three types of scores (scaled score, age equivalent, and GSV). Post-hoc power calculations yielded estimates for sample sizes (per group) required to detect the observed effects with 80% power in future studies.

Methods: The interview form of the VABS-3 was administered to parents during study visits spaced at 6-month intervals. Here, we used data from the 14 participants with histories of global developmental delay and varying degrees of autism symptomatology who completed baseline and 6

month visits (age M=7.1, SD=3.6, range 3 – 13 years; VABS-3 Adaptive Behavior Composite Score M=47.9, SD=15.6, range 20-69). Linear mixed models were used to estimate mean change and the standard error of that estimate.

Results: Preliminary data indicate that for most subdomains, effect sizes were largest for GSV scores (see Figure 1). In some cases, the V-Scale effect size was the largest; however, V-scale in these cases indicated a worsening of relative standing, while the GSV indicated slight improvement or stability (e.g., Playtime). Where both the V-Scale and GSV indicated improvement over 6 months, the decrease in required sample size associated with use of GSV ranged from 43% to 83%. For example, the required sample size for Receptive Language GSV was n=26, compared to n=42 and n=46 for AE and V-scale, respectively.

Conclusions: Scaled or standard scores are poorly suited for use as outcomes in clinical trials because detectable changes in relative standing require proportionally larger changes in ability. The VABS-3 contains GSV, which index ability and are therefore explicitly designed for the assessment of within-person change. Using data from a natural history study of CTD, we demonstrated that studies which use GSV rather than scaled scores will require significantly fewer participants and will be less likely to mistake slower-than-expected growth as decline.

75 **204.075** Vineland™-II Adaptive Behavior Scales for Autism Spectrum Disorder: An Electronic Version Is Conceptually Equivalent to the Standard Paper Version

T. Willgoss[1], *G. Deol-Bhullar*[2], *R. Swinhoe*[1] *and J. W. Smith*[1], *(1)F. Hoffmann-La Roche Ltd., Welwyn Garden City, United Kingdom, (2)F. Hoffmann-La Roche Ltd., Basel, Switzerland*

Background: The Vineland Adaptive Behavior Scales, Second Edition (Vineland™-II) is a semi-structured interview-based clinical outcome assessment (COA) that is administered by a trained healthcare professional to the individual's caregiver/study partner. It assesses core domains of adaptive behavior and is recognized as an appropriate primary outcome measure for clinical trials in autism spectrum disorder (ASD). The Vineland-II is traditionally administered in paper format, but an electronic, tablet-based version has recently been developed for multicenter clinical trials.

Objectives: Regulatory guidance requires that whenever a COA is administered in a new mode, evidence is required to demonstrate that the COA's measurement properties are equivalent or superior to the data produced from the original version. Thus, the objective of this study was to explore conceptual equivalence and usability of the electronic version of the Vineland-II compared with its original paper format.

Methods: Qualitative, face-to-face interviews were conducted with 10 healthcare professionals in the United States who had experience administering the paper version of the Vineland-II and treating patients with ASD. Interviews were split into 4 sections: training the healthcare professional on the use of the electronic Vineland-II; a mock-administration exercise; and 2 debriefing sessions, 1 for each mode of the Vineland-II. All interviews were digitally recorded and transcribed verbatim. Qualitative analysis was conducted on all transcripts by sorting quotes into concepts using thematic analysis methods using a qualitative data analysis and research software (ATLAS.ti).

Results: All 10 participants were able to successfully use the electronic version of the Vineland-II on a tablet and experienced no significant issues in completion. There were no apparent differences between levels of understanding of the instructions and items for the paper and electronic versions. No participants reported differences in how the items on the paper and electronic versions of the Vineland-II were displayed or suggested ways in which the items could be displayed better on the electronic version. No notable differences were identified between calculating and interpreting scores on the electronic and paper versions of the Vineland-II, and both modalities were considered equally acceptable and easy to use. All participants reported that they would complete both versions in the same manner, and that they would be comfortable completing the electronic version in a clinical trial setting.

Conclusions: This qualitative research with healthcare professionals provides strong evidence that the newly developed electronic version of the Vineland-II is conceptually equivalent to the original paper version. The evidence from this study supports the use of an electronic version of Vineland-II in multicenter clinical trials for ASD.

76 **204.076** 'Play As You Do at Home': Using the Who Adapted Joint Engagement Rating Inventory (JERI) to Measure Caregiver-Child Interaction

E. Salomone[1,2], *M. Settanni*[1], *F. Ferrara*[1], *G. Foletti*[3], *C. Servili*[2], *K. Suma*[4], *R. Bakeman*[4] *and L. B. Adamson*[4], *(1)Department of Psychology, University of Turin, Turin, Italy, (2)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (3)University of Turin, Torino, Italy, (4)Psychology, Georgia State University, Atlanta, GA*

Background: Recent literature has highlighted the need for comprehensive instruments to measure targets for early intervention for developmental disorders and delays, including autism spectrum disorder (ASD). The WHO adaptation of the Joint Engagement Rating Inventory (WHO JERI, Adamson, Bakeman & Suma, 2018) is a 12-item inventory developed to measure relevant intervention targets (Table). Items rate a child's engagement states as well as aspects of the child's behavior, their caregiver's behavior and the dyad's shared activities.
Objectives: to examine observers' agreement, accuracy, and construct validity of the WHO JERI

Methods: The sample consists of 86 children with ASD (67 males) aged 28-60 months recruited for a randomized controlled trial of the WHO Caregiver Skills Training program. Autism severity (ADOS-2), cognitive abilities (Griffiths-III) and vocabulary (MCDI) measures were collected at baseline. A free play caregiver/child interaction with a standard toy kit suitable for a range of developmental play levels was videorecorded. Ten consecutive minutes were rated both with a measure of social communication (BOSCC) and the WHO JERI by two reliable raters blind to the study's hypotheses. Rating procedures were applied as per the manual for both measures. For the BOSCC, averaged scores were obtained for two 5-min scenes that were scored separately. For the WHO JERI, ratings of child engagement state (e.g., joint engagement); child behavior (e.g., initiation of communication, expressive language); caregiver behavior (e.g., following-in, affect); and the dyadic interaction (fluency and connectedness, shared routines) were applied to the entire 10-min scene in three separate viewings. Preliminary analysis were conducted on a partial sample (n=22, 17 males). To check agreement, 50% of the corpus was independently rated by a second observer. Estimated observer accuracy was computed using the KappaAcc program (Bakeman & Quera, 2011; Bakeman, 2018). Construct validity of the WHO JERI was investigated by examining the associations of the WHO JERI item scores with theoretically associated variables on other assessments.

Results: Observers' agreement was reasonable: the range of weighted Kappas for ratings within 1 point on the 7-point rating scale was .64–1. Observer accuracy was acceptable, with 8 out of 12 items showing accuracy higher than 99%. JERI Unengaged and Joint Engagement items show

strong (> .5) positive and negative correlations with BOSCC and ADOS composite scores and items covering similar constructs (Spearman r's range= .68 to .89 and -.76 to -.97, respectively). Correlations between JERI child items and corresponding BOSCC items (range = -.75 to -.85) were higher than correlations with expressive vocabulary or developmental level. Caregiver behavior items were weakly correlated with child skills, with the exception of expected relationships: e.g. Following-in was negatively correlated with repetitive behaviors (r=-.67). Interaction items were strongly correlated with the BOSCC engagement item (range = -.71 to -.86).

Conclusions: The WHO JERI shows reasonable inter-rater agreement. Examination of correlations supports the tool's construct validity, as the patterns of both the direction and size of correlations shown among WHO JERI items and other study variables are consistent with previous studies and theoretical expectations.

Poster Session
205 - Cognition: Attention, Learning, Memory
5:30 PM - 7:00 PM - Room: 710

77 **205.077** Looking at the Ceiling: Eye-Tracking Data Indicate a Restricted Range of Reactivity to Threat in Autism

C. A. Larson[1], *D. N. Top*[2], *K. Smith*[2], *A. N. Bennion*[3], *C. Rich*[2] *and M. South*[4], *(1)Neuroscience, Brigham Young University, Provo, UT, (2)Brigham Young University, Provo, UT, (3)Psychology, Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT*

Background: High levels of anxiety in autism have been linked to a number of mechanisms including the idea of reduced emotional awareness described as "alexithymia". In a previous fMRI study of classical fear conditioning, we found less differentiation of threat and safe contexts in autism. We suggested one possible reason for this could be a "ceiling effect" in which autistic participants were already so physiological elevated (whether from everyday life or the context of the experiment, or both) that further reactivity to our threat task is limited. For this experiment, a similar fMRI study of fear conditioning with a less variable reinforcement schedule, we additionally collected eye tracking data as fast (millisecond response, as opposed to a multiple second time course for fMRI BOLD data) measure of threat reactivity, and we also added a non-task baseline condition to examine initial tonic pupil size.
Objectives: We explored non-task "baseline" data for evidence of hyperarousal in autism *before* the onset of our fear conditioning experiment, and subsequent changes in pupil size during the experiment. We explicitly explored the possibility of a "ceiling effect" that influences the possible range of response in autism.

Methods: Sixty young adults (28 autism, 32 neurotypical) with average- to above-average IQ completed a classical fear conditioning task that used visual cues as conditioned (threat versus safe) cues and a burst of air on the neck as the unconditioned threat stimulus. Using Eyelink 1000 Plus eye-tracking system we collected tonic pupil size while participants stared at a fixation cross in the center of the screen for 60 seconds, and change in pupil size following the onset of each cue (threat or safe) during the fear conditioning task.

Results: The autism group demonstrated significantly elevated tonic pupil size compared to matched neurotypical participants, before the test even started. During the fear conditioning task, the autism group demonstrated a restricted range of response, including decreased responses to both safe and threat conditions and a decreased difference between safe and threat in the autism group.

Conclusions: While there are several possible explanations for this reduced reactivity during the fear conditioning task, we suggest that a "ceiling effect" arising from the elevated baseline arousal is parsimonious. The experimental threat of the air burst to the neck was not enough in thautism group to overcome existing arousal, which could be due to pressure or anxiety from the MRI environment and/or from everyday arousal. this latter possibility suggest the need to study physiological activity and response over the course of days or weeks using ecologically-valid methods. In the meantime, treatment for anxiety in autism should acknowledge difficulties latching on to "safe" contexts and possibly an elevated everyday physiological arousal which could interfere with relationships, work/school performance, and therapy.

78 **205.078** Luminance- and Texture-Defined Visual Perceptual Processing in Children and Adolescents with Asd; Comparison with Other Neurodevelopmental Conditions

M. Miseros, *D. Tullo and A. Bertone, McGill University, Montreal, QC, Canada*

Background: Individuals with Autism Spectrum Disorder (ASD) possess unique capacities related to visual perception (Mottron et al., 2006). Their capabilities can be defined by performance on behavioural tasks assessing low-level, basic visual information processing. An increasing trend in autism research has been defining the perceptual phenotypes in ASD and other neurodevelopmental conditions (NDCs) by conceptualizing atypical visuo-perceptual processes usingtwo models; the dorsal stream vulnerability hypothesis (Braddick et al, 2011) and the complexity-specific (CS) hypothesis (Bertone et al., 2005). Whereas the former is defined by findings of less efficient dynamic information processes across NDCs, the latter suggests neuro-integrative dysfunction leading to decreased sensitivity to complex visual information. Despite progress in defining visuo-perceptual profiles in ASD and other NDCs, findings are often inconsistent due to the use of different tasks across clinical groups, and participant groups in the literature are predominantly adults with average or above average cognitive abilities.
Objectives: Thepresent study (i) assessed visuo-perceptual profiles (processing of static and dynamic stimuli of varying complexity) in youth with ASD and other NDCs, and (ii) explored the extension of the CS hypothesis to a non-adult ASD population.

Methods: This study employed a single interval, two alternative (spatial) forced-choice orientation-discrimination paradigm to assess the processing of luminance- (simple) and texture-defined (complex) gratings presented in both static and dynamic states for 101 children and adolescents (aged 5 to 17 years). Participant groups either had a primary diagnosis of ASD (n=32), a non-ASD NDC (i.e., ADHD, ID and LD; NDC; n=26) or were typically developing (TD; n=43); groups were matched for mental age (MA), (p=.10), defined by an assessment of cognitive ability using the Wechsler Abbreviated Scale of Intelligence (WASI-II). Orientation-discrimination thresholds (luminance- and contrast-modulation thresholds) were calculated for each condition across groups; performance was assessed in relation to MA.

Results: The performance of the ASD group was comparable to the TD group, whereas the NDC group demonstrated reduced performance for second-order dynamic stimuli, suggesting that the CS hypothesis can define perceptual abilities of younger individuals with a non-ASD NDC. While results are not consistent with the adult-based CS hypothesis, significant correlations were found between MA and ASD perceptual discrimination

thresholds in all conditions: r [-.49, -.41, -.55], with the exception of the luminance-defined, dynamic information condition.This relationship, demonstrating that discrimination thresholds decrease with increasing mental age, suggests the visuo-perceptual *profile* of individuals with ASD changes with MA.

Conclusions: This study provides valuable information regarding the respective maturation of both dynamic and static early perceptual abilities across childhood and adolescence in ASD compared to MA-matched NDC and TD groups. Findings extend the literature by evaluating the integrity of the dorsal and ventral visual streams in clinical groups, and contribute to the developmental and condition-specific conceptualization of visuo-perceptual processing in ASD. Overall, the results support the applicability of the CS hypothesis to other NDCs, and highlight the relationship between visuo-perceptual profiles and overall cognitive abilities (i.e., MA) in ASD. Future research should assess perceptual abilities in ASD and other NDCs within a developmental context.

79 **205.079** Modulation of Task-Evoked Pupil Dilations Differs in Individuals with Autism Spectrum Disorders: Implications for Noradrenergic and Cholinergic Dysfunction in ASD

M. C. Granovetter[1,2], *C. S. Burlingham*[3], *D. J. Heeger*[3] *and M. Behrmann*[1], *(1)Carnegie Mellon University, Pittsburgh, PA, (2)University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)New York University, New York, NY*

Background: It has been posited that cognitive deficits among individuals with autism spectrum disorders (ASD) are a consequence of an imbalance in cortical excitation and inhibition. The noradrenergic and cholinergic systems have been implicated in globally modulating the homeostasis of excitatory and inhibitory neural activity and, accordingly, regulating cognitive processes such as attention, memory, and learning. Importantly, the noradrenergic system is critical for attending to task-relevant stimuli, a behavior that can be challenging for individuals with ASD. Whether there are inherent differences in the release of norepinephrine and/or acetylcholine in individuals with ASD, and the potential impact of these differences on their behaviors, remains unclear.

Objectives: The goal of this study was to determine whether, relative to matched typically developed participants, individuals with ASD exhibit differences in task-evoked pupil dilations under conditions of cognitive load. Any such difference might implicate atypicalities in the regulation of the noradrenergic and cholinergic systems in ASD.

Methods: 17 participants with ASD (15 males, 2 females; mean ± SD age = 32 ± 7.6 years) and 14 neurotypical controls (12 males, 2 females; mean ± SD age = 27 ± 4.5 years) performed a one-back working memory letter detection task (with stimuli presented every 0.5 s), while pupil size was measured at a rate of 1000 Hz. In half of trials, participants were also exposed to distractor auditory tones played at random intervals throughout the block. Feedback on hits and false alarms was displayed to participants in real time.

Results: A repeated-measures ANOVA revealed no significant group differences on either sensitivity indices or reaction times, indicating comparable performance between the two groups. A support vector machine was trained using cross-validation on the impulse response function (IRF) of pupil size in response to hits and was able to classify the two groups on diagnosis with above-chance accuracy. To evaluate differences in the magnitude of pupil size fluctuations between the two groups, a repeated-measures ANOVA was performed on the response amplitudes of the pupil size IRFs in response to hits, false alarms, and misses, for both task conditions (with/without distractor stimuli). There was a significant main effect of group on pupil response amplitudes, as well as a significant interaction of group by task condition. Post-hoc analyses indicate that whereas the pupil response amplitudes are not different across conditions for controls, for participants with ASD, the pupil response amplitudes were significantly lower when distractor stimuli were present compared to when they were absent.

Conclusions: These findings suggest that measurement of task-evoked pupil dilations allows for classification of individuals with ASD from neurotypical controls. Notably, when individuals with ASD successfully perform a cognitive task, the extent of pupil size fluctuation is nonetheless smaller when distractor stimuli are present. It is thus possible that individuals with ASD might exhibit atypical activity of the noradrenergic and cholinergic systems when attempting to attend to task-relevant stimuli.

80 **205.080** Patterns of Learning in Young Children with Autism Spectrum Disorders

S. C. Bauer[1], *Y. Li*[2], *R. A. deRegnier*[3], *D. M. Brazdziunas*[4], *J. Stanczak*[5] *and M. Weissbourd*[6], *(1)Pediatric Developmental Center at Illinois Masonic Medical Center, Advocate Children's Hospital, Chicago, IL, (2)Advocate Center for Pediatric Research, Advocate Children's Hospital, Oak Lawn, IL, (3)Pediatrics - Neonatology, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (4)Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (5)Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, (6)Child Psychology and Psychiatry, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL*

Background:

Understanding the cognitive profile of children with autism spectrum disorders (ASD) is important to determining whether there is a pattern that is unique to this learning style, potentially informing prognosis and targeting appropriate interventions.

Objectives:

The purpose of this pilot study was to examine the pattern of language and nonverbal intelligence in young children with ASD as measured on standardized developmental and achievement testing as a way to guide future therapeutic and educational interventions.

Methods:

The study design was a retrospective chart review of 168 children with ASD (median age 4.11 years; SD=1.08) evaluated at Lurie Children's Development Clinic from 8/1/11 to 8/1/16. The following data was extracted from the electronic medical record: date of visit, date of birth, sex, race and ethnicity, educational and therapeutic interventions, and testing results.

Statistical analyses utilized included Student's t-test and paired t-test, Chi-squared tests and the use of the Bonferroni correction when appropriate. A two-sided p value ≤ 0.05 was considered statistically significant.

Results:

Of the 168 children, 80% were male and 20% were female. In regards to ethnicity, 56% were Caucasian, 26% Hispanic, 13% African American, and 5% responded as "other" or did not report ethnicity.

Sixty-six percent of the sample attended school. Ten percent attended a general education preschool classroom with the remaining in special

education settings. Forty-three percent received school based therapy services. Sixteen percent participated in applied behavior analysis therapy (ABA).

Fifty-three participants were evaluated using the *Bayley Scales of Infant Development- Third Edition* due to lower developmental attainment. They were significantly younger when first diagnosed with ASD (x=4.27, SD=0.9, p<0.0005), suggesting that they required increased levels of support.

One hundred nineteen children completed all of the subtests on the *Differential Abilities Scales, Second Edition***.** The mean GCA score was 77; the mean verbal score was 73; the mean nonverbal score was 82; the mean spatial score was 83. A significant difference was found between verbal and nonverbal reasoning scores, with nonverbal skills being higher (mean difference 7.5, p<0.0005).

Eighty-five children completed all of the subtests on the *Bracken School Readiness Assessment*. Composite scores fell in the average range (mean 93, SD=16.7). Significant differences between subtests on the *Bracken* were found. Identifying colors, shapes, letters and numbers were strengths in our population as all fell in the average range. Understanding of size/set comparisons (B-R-S/C), a more language based skill, fell significantly below the mean (x=4.17, SD= 3.736). Performance on this subtest was found to be significantly higher among subjects attending school (mean 4.53, SD=3.836, p=0.004).

Conclusions:

School attendance correlated with more flexible thinking as indicated by improved scores on the set comparisons subtest of the *Bracken*. Children with ASD display a unique learning style characterized by strengths in visual learning and memory. Future research is required to understand the effects of school and socioeconomic status on learning performance.

81 **205.081** Patterns of Nonsocial and Social Cognitive Functioning in Adults with Autism Spectrum Disorder: A Systematic Review and Meta-Analysis

T. Velikonja[1], *E. Velthorst*[2] *and A. K. Fett*[3], *(1)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Icahn School of Medicine at Mount Sinai, New York, NY, (3)Department of Psychology, City University of London, London, United Kingdom*

Background: Despite similar Autism Spectrum Disorders (ASD) prevalence rates of 1% in children and adults, and clear challenges that persist into adulthood, research and treatment efforts have been largely dedicated to children. A critical question that has remained largely unaddressed concerns the identification of cognitive domains that are most severely impaired in adults with an ASD diagnosis. A detailed evaluation and comparison of (social) cognitive deficits in adults with ASD will advance knowledge about the expression of ASD in later life, and may help pinpoint targets for (social) cognitive intervention.

Objectives: The present review and meta-analysis aims to systematically map the severity of impairments across domains of non-social and social cognitive functioning in adults with ASD compared to the neurotypical adult population. To help explain any variability between studies, potential moderators of impairments observed in these individuals will be evaluated.

Methods: The literature search was conducted in PubMed, PsycINFO, EMBASE and MEDLINE databases. The search was limited to studies published between 1980 (first inclusion of Autism diagnosis in the DSM-III) and July 2018. Studies were included if they were published as primary peer-reviewed research paper in English, included individuals with Autism Spectrum Disorder (ASD) aged 16 or over and assessed at least one domain of neurocognitive functioning or social cognition using standard measure(s). In total, 9829 potentially eligible papers were identified and screened, 75 studies met inclusion criteria for meta-analysis.

Results: Most of the 75 studies included in the meta-analysis were conducted in Europe (n=50, 67%), followed by studies from the USA and Canada (n=16, 21%). The sample sizes varied greatly, ranging from 18 to 3907 participants (including neurotypical adults) with 66 (88%) studies using samples between 20 and 100 participants. All the included studies had a combined sample of 3361 individuals with ASD and 5344 neurotypical adults. Adults with ASD showed large impairments in theory of mind (Effect size (ES) g=-1.09, 95% CI=-1.25 to -0.92; number of studies=39) and emotion perception and knowledge (ES=-0.80, 95% CI=-1.04 to -0.55; n=18), followed by medium impairments in processing speed (ES=-0.61, 95% CI=-0.83 to -0.38; n=21) and verbal learning and memory (ES=-0.55, 95% CI=-0.86 to -0.25; n=12). The relatively spared cognitive domains were working memory (ES=-0.23, 95% CI=-0.47 to 0.09; n=19) and attention and vigilance (ES=-0.30, 95% CI=-0.81 to 0.21; n=5). Meta-regressions confirmed robustness of the results.

Conclusions: This comprehensive review and meta-analysis of impairments in non-social cognitive functioning and social cognition of verbal adults with ASD showed that despite having an intact IQ, there are medium to large deficits observed in four key-domains of social and non-social cognition (Theory of Mind, Emotion perception and knowledge, Processing speed and Verbal learning and memory). While our findings support the key social cognitive theories of ASD, they also stress deficits in non-social cognitive areas. These results highlight the importance of a broader approach when studying cognition, also as potential mechanism underlying symptoms and treatment outcomes.

82 **205.082** What Strategies Do Autistic Children Use When Learning New Categories? an Eye-Tracking Study

A. M. Nader[1], *D. Tullo*[2], *A. Bertone*[2] *and I. Soulieres*[3], *(1)University of Quebec in Montreal, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada, (3)Psychology, University of Quebec in Montreal, Montréal, QC, Canada*

Background: Autistics have shown a range of performance on category learning tasks (Gastgeb et al., 2012; Schipul et al., 2012; Soulières et al., 2011), possibly associated with differences in how they process learned material (e.g., reduced attention to social elements, attend to fewer elements). Recent studies have tried to understand how and when autistics learn efficiently (Foti et al., 2015), including by spontaneously extracting regularities from large arrays of information (Mottron et al., 2013). Such findings suggest that how information is presented may affect the way autistics explore their visual environment, ultimately affecting leaning.

Objectives: To study how autistic and typically-developing children process new information during a probabilistic categorization task, and specifically; 1) Do autistics attend to the same stimulus elements and show the same pattern of preferences compared to typical children?, and 2) Do the learning strategies used by the autistic children differ according to the way material is presented?

Methods: 38 autistic (M_{age} 10.1 years, SD 1.9; $M_{WISC\text{-}IV\ PRI}$ 102.5, SD 22.7) and 43 typically-developing (M_{age} 9.4 years, SD 1.4, p>.05; M_{PRI} 111.6, SD 20.9, p>.05) children completed two sets of probabilistic categorization tasks (*Nader et al., 2018*) using a Tobii T120 eye tracker. Fourteen artificial stimuli varying across 4 features had to be classified into 2 categories based on 5 different probabilities. Each stimulus was probabilistically

associated with an outcome. Tasks varied in the way information was presented; (1) one item at a time with feedback (sequentially), or (2) a non-feedback version of the task with the observation of the items-outcome association (simultaneously). A 200-trial learning phase preceded a test phase in which each stimulus was presented twice (total 28 trials), and eye tracking data collected. All stimuli were partitioned into 4 areas of interest (AOI) (4 main features of the stimuli), which could be either present or absent on a given stimulus. Analyses were conducted on the length and the frequency with which children attended to the different AOIs on items containing most of the AOI (i.e. presence of 3 features out of 4). Further analyses are ongoing.

Results: Consistent with Nader et al. (2018), performance of autistic children was better -and similar to that of typically-developing children- when information was presented simultaneously, and decreased when presented sequentially. Collapsed across conditions, both groups attended to the same features, but with autistics having shorter and reduced number of fixations on AOIs than typically-developing children. Interestingly, autistic displayed less (F (1, 37) 6.2, p=.02) and shorter (F (1, 37) 7.7 p=.009) fixations than typical children when information was presented simultaneously during learning, while the length and the frequency were similar for both groups when information was presented sequentially (p>.05).

Conclusions: In a probabilistic category learning task, autistic children based their learning using the same features as typically-developing children, but were more efficient when information was presented simultaneously, resulting in a reduction in information processing time. These findings suggest increasing access to information (i.e., simultaneous) while learning may be beneficial for autistic children.

83 **205.083** Possible Mechanisms for Elevated Pupil Size in Autistic Adults

K. Smith[1], *D. N. Top*[1], *I. Wu*[1], *C. A. Larson*[2], *A. N. Bennion*[3], *T. White*[1], *C. Rich*[1], *L. Hall*[1] *and M. South*[4], *(1)Brigham Young University, Provo, UT, (2)Neuroscience, Brigham Young University, Provo, UT, (3)Psychology, Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT*

Background: Increases in pupil size dilation has been associated with emotional salience and greater cognitive load. A series of studies by Tsukahara, et al. (2016) have reported a positive correlation between tonic pupil size and higher fluid intelligence and working memory performance, suggesting that persons with high tonic pupil size also have a higher capacity or cognitive load. Studies of autistic samples have found higher tonic pupil sizes in autism (AUT) compared to neurotypical (NT) samples, which could be due to cognitive factors but could also be due to elevated emotional arousal. To date, there has not been a study examining the relationship between tonic pupil size, cognitive functioning, and emotional distress in an autism sample.

Objectives: To explore the relationship between tonic pupil size, cognitive ability, and emotional distress in both neurotypical and autistic adults.

Methods: Participants were autistic (n=26) and neurotypical (n=24) adults who were part of a larger study on emotion learning in autism. We collected tonic pupil size using using Eyelink 1000 Plus eye-tracking system while participants stared at a fixation cross in the center of the screen for 60 seconds. We administered the WAIS-IV to all participants to identify cognitive ability using standard subtests and domains. We measured emotional distress using the Depression, Anxiety, and Stress Scale Short Form and the Penn State Worry Questionnaire. We calculated differences between the AUT and NT groups using t-tests in all measures, and also examined possible correlations between variables using a Pearson's correlation.

Results: Analyses confirmed previous findings of larger tonic pupil size in AUT compared to NT group participants (p= .011). The AUT group also had a higher emotional distress scores on the DASS (p<.001) and PSWQ (p<.001). Groups were evenly matched for Verbal Comprehension and Perceptual Reasoning domains of the WAIS-IV but the AUT group scored lower on the Working Memory (p=.011), and Processing Speed (p<.001) domains. However, there were no significant correlations between pupil size and cognitive ability or emotional distress, for either group separately or for the combined samples.

Conclusions: At least in this small sample, the higher pupil size in AUT does not seem to be related to increased cognitive abilities as extrapolated from Tsukahara, et al. (2016). However, we also found no correlations with emotional distress. Cognitive and emotional reactivity--how one responds to a challenging task--may be interesting to study in relation to pupil size. At present, however, we do not have an explanation for the consistent physiological difference of larger tonic pupil size in autism and future studies of both physical and psychological factors are needed to shed light on this phenomenon.

84 **205.084** Proactive Control Preserved but Related to Internalizing Psychopathology in Adolescents and Young Adults with Autism Spectrum Disorder

M. K. Krug[1], *M. V. Elliott*[2], *C. C. Coleman*[1], *J. P. Hogeveen*[3] *and M. Solomon*[1], *(1)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA, (2)Department of Psychology, University of California, Berkeley, Berkeley, CA, (3)Department of Psychology, University of New Mexico, Albuquerque, NM*

Background:

Autism spectrum disorder (ASD) is characterized by deficits in cognitive control (Solomon, Hogeveen, Libero, & Nordahl, 2017). However, recent work has shown that proactive control, defined as preparatory, goal-directed cognitive processing, may be preserved in children with ASD, and its implementation negatively associated with attention problems (Hogeveen, Krug, Elliott, & Solomon, 2018). Proactive control has not yet been investigated in adolescents and young adults with ASD, nor have its associations with anxiety and depression, which are commonly comorbid in ASD (Leyfer et al., 2006), increase in prevalence during adolescence (Mayes, Calhoun, Murray, & Zahid, 2011), and are associated with impaired cognitive control in typical development (Eysenck, Derakshan, Santos, & Calvo, 2007; Joorman & Tanovic, 2015).

Objectives:

1. Determine whether proactive control is intact in adolescents and young adults with ASD compared to age and IQ-matched typically developing individuals (TYP).
2. Determine whether implementation of proactive control is negatively associated with symptoms of attention deficit and hyperactivity (AD/H), anxiety, and depression.

Methods:

44 ASD (Age=17.6 (2.9); FSIQ=104.2 (12.7)) and 44 TYP participants (Age=17.2 (3.2); FSIQ=107.6 (11.9)) performed a picture-word Stroop task (Gonthier, Braver, & Bugg, 2016; Figure 1a). Participants were instructed to name the animal pictured while ignoring a superimposed response-congruent (C) or response-incongruent (I) word. Two blocks of the task were performed: a mostly congruent (MC) block, where most of the trials were C, and a mostly incongruent (MI) block, where most of the trials were I. For MC and MI blocks, response time (RT) interference effects were calculated (I RT–C RT). If many I trials are encountered, as in the MI block, participants should adopt a proactive control strategy, whereby they focus more on the picture and ignore the word, resulting in decreased RT interference. Proactive Control Benefit was calculated as a reduction in interference on the MI block in comparison to the MC block (MC_I–C RT) – (MI_I-C RT).

Psychopathology (DSM scales for AD/H, Depression, and Anxiety) was assessed with the parent-report Achenbach System of Empirically Based Assessment (ASEBA) (Achenbach & Rescorla, 2001; 2003).

Results:

ASD and TYP did not differ in MC interference (F=.150, p=.700), MI interference (F=.875, p=.352), or Proactive Control Benefit (T=.403, p=.688) (Figure 1b). In the ASD group, MC interference, MI interference and Proactive Control Benefit were not associated with AD/H symptoms. However, MI interference was positively correlated with anxiety (rho=.307, p=.043) and depression symptoms (rho=.360, p=.016) (Figure 2a) and Proactive Control Benefit decreased as symptoms of depression increased (rho=-.320, p=.034)(Figure 2b).

Conclusions:

Proactive control is not impaired in adolescents and young adults with ASD, replicating findings in children. However, anxiety and depression are associated with increased interference in proactive control-demanding contexts, and depression is associated with reduced implementation of proactive control. Thus, while some important underlying mechanisms of cognitive control may be intact in those with ASD, the presence of co-morbid psychopathology can negatively affect cognitive functioning in these individuals, and should be considered when diagnosing and treating their challenges in social, academic, and general adaptive functioning.

85 **205.085** Reading Abilities of Hebrew Speakers with ASD

ABSTRACT WITHDRAWN

Background:

Studies of reading in ASD mainly focused on text reading and comprehension. They report that children with ASD read at their age-level, but exhibit reading comprehension difficulties and difficulties in reading in context.

Objectives:

This study is the first to test reading abilities at the word level and analyse error types in ASD. Its aim was to assess their reading in the framework of the Dual Route Model and if they show difficulties, identify the locus of impairment within the reading process.

Methods:

Participants were 70 Hebrew speakers with ASD aged 8-27 (M=15.8, SD=4.8; 9 female, 61 male). All were diagnosed with ASD prior to the study. Control groups for each ASD participant were age-matched individuals with no known developmental disorders.

The participants' reading was evaluated using the TILTAN reading screening task, which includes reading of 136 single words, 40 nonwords, and 60 words presented in pairs. Correct responses were counted and in-depth error analysis was made to detect different types of dyslexia.

Results:

The analysis of accuracy and error types yielded three reading profiles : Intact reading (n=36), dyslexia (n=22), and reading deficits as a result of an impairment in lexical retrieval (n=12). Namely, for half of the participants, reading itself was unimpaired.

Of the ASD participants with dyslexia, the most common pattern was that of reading via grapheme-to-phoneme conversion, instead of reading through the lexical route (which may also explain their semantic difficulties in text reading); 9 other ASD participants with dyslexia had impairments in orthographic-visual analysis, mainly in letter position encoding (letter position dyslexia) or letter-to-word binding (attentional dyslexia).

Conclusions:

This study was the first to assess the reading abilities of Hebrew-speaking participants with ASD. More than half of the participants had age equivalent reading abilities. Three main types of dyslexia's were found, an important finding when considering educational and intervention programs.

86 **205.086** Real-World Social Problem-Solving in ASD: The Influence of Executive Functions

***M. Stabile**, S. R. Dokuru, B. Castelluccio, A. R. Canfield, A. Hogstrom, J. J. Green and I. M. Eigsti, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Social communication impairments in individuals with autism spectrum disorder (ASD) are associated with executive function deficits. However, much of this work relies on standardized assessments. The current study utilized a task designed to elicit spontaneous language between two speakers; the task has high ecological validity; we argue that it is more representative of real-world language skills than performance on the item-by-item probes of a standardized assessment.

Objectives: This work examined diagnostic differences in a novel measure of accuracy on a social communication task, and associations between task performance and executive function, social communication, and verbal IQ skills. We hypothesized that adolescents with ASD would underperform in a social problem-solving task, and that their difficulties would reflect individual differences in executive function (especially planning, working memory and inhibition).

Methods: A total of 29 adolescents (15 TD, 14 ASD) completed a social communication task in which participants collaborated verbally with an undergraduate research assistant (RA; naive to study hypotheses) to navigate a series of maps (Anderson et al., 1991). Participants alternated between “Tourist” and “Guide” roles, completing six maps. “Guide” maps (Figure 1a) contained a route drawn from a starting point through a

series of landmarks to a finish point; the corresponding "Tourist" map contained similar landmarks without the route. There were three non-shared landmarks on each map. Guide and Tourist routes were converted to digital format for analysis in Photoshop (Figure 1b). Route accuracy was operationalized as the number of pixels contained within the area formed by the spatial difference between correct and drawn routes (Figure 1c). Participants also completed the Stanford Binet Vocabulary subtest; parents completed the BRIEF parent report form, as a measure of executive skills, and the Social Communication Questionnaire (SCQ) and the ADOS (ASD group only) as measures of symptomatology.

Results: Route accuracy was lower for ASD+RA pairs, F=8.61, p = .007, suggesting less efficient route-drawing. Group differences held whether the participant or RA was drawing the route, indicating that group differences were not due to fine motor control. Correlational analyses across groups revealed that route accuracy was associated with global executive functions (BRIEF GEC scores), r = .55, p = .002, and with Vocabulary scores, r = -.38, p = .04 (correlations were similar within each group). When the participant was the Guide, route accuracy for ASD+RA pairs was associated with ADOS communication domain scores, r(14)=.60, p=.02; this was not the case when the RA was the guide, p =.46.

Conclusions: When describing navigational routes to a study-naïve RA, adolescents with ASD had greater difficulty in communicating about those routes; individual differences reflected both executive skills, and also ASD symptom severity (as indexed by the ADOS). Route accuracy was apparently influenced by communication strategies. Task discourse analyses (currently underway) of **turn-taking**, **shared vocabulary**, and **clarification of misunderstandings**, can reveal specific aspects of communication that promote or inhibit more effective communication. As such, findings will assist in identifying optimal targets for intervention, to support better communication.

87 **205.087** Recognition of Event Information By Children with Autism Spectrum Disorders

S. G. Ruggiero[1], *S. L. Armstrong*[1], *S. Manevich*[1], *M. Meleka*[1], *L. K. Steinbeck*[1], *B. C. Lyman*[2] *and P. Wilson*[1], *(1)La Salle University, Philadelphia, PA, (2)Autism Spectrum Diagnostics and Consulting, Doylestown, PA*

Background:

General event representations (GERs, aka *cognitive scripts* or *event schemas*) consist of the actors, props, and spatiotemporal sequences of expected actions that occur during familiar events (Slackman, Hudson, & Fivush, 1986; Hudson & Mayhew, 2009). GERs are important for predicting the progression and outcomes of future experiences and planning for social interactions.

Children with ASD typically exhibit deficits in social communication and their narratives are often disorganized, have limited causal connections, and reveal lack of understanding of the main idea. Therefore, the question arises as to whether children with ASD are able to recruit GERs for these activities. Prior research examining children with ASD has been inconsistent regarding whether they successfully use GERs similarly to neurotypical (NT) children (Trillingsgaard, 1999; Loth, 2007; Volden & Johnston, 1999).

Objectives:

This study investigated whether high-functioning (FSIQ ≥80) children with ASD, ages 6-12, can effectively recruit GERs for common, social events. The current study improved on previous methodological and procedural techniques by employing more stringent matching procedures based on chronological age and overall cognitive abilities.

Methods:

- Participants
  - The total included 19 matched pairs of NT children (6 males; 13 females) and children with ASD (18 males; 1 female). Participants were matched within one year of their ages (6.8 to 12.6 years) and on overall cognitive abilities (FSIQ scores 81-122).
- GER Recognition Task (Replicating Volden & Johnston, 1999)
  - Children were shown a sequenced set of drawings portraying 3 familiar events (restaurant, supermarket, movie theater). Twice per sequence a drawing was shown that disrupted the script. As each drawing was shown, the experimenter asked, "*Are things happening as they should?*" Responses were audiotaped and coded to determine children's correct identification of script disruptions, omission errors, commission errors, and types of commission errors.

Results:

	Correct Disruption Identification	**Commission Errors**	**Omission Errors**
Group			
Restaurant GER	**M(SD)**	**M(SD)**	**M(SD)**
ASD	1.32(.58)	1.89(1.10)	0.79(.63)
NT	1.37(.76)	1.53(1.35)	0.63(.76)
Supermarket GER			
ASD	1.37(.60)	0.89(.74)	0.63(.60)
NT	1.37(.60)	1.05(.78)	0.63(.60)
Movie Theater GER			
ASD	1.21(.71)	1.00(.82)	0.79(.71)
NT	0.95(.62)	1.32(.67)	1.05(.62)

A 2(Grp)X3(EventType) ANOVA revealed no effect of Group (F(1)=.24, p=.629) and no effect of Event Type GER on Correct Disruption Identification (F(2)=2.90,p=.060.

A 2(Grp)X3(EventType) ANOVA revealed no effect of Group (F(2)=0.04, p=.856), a main effect of Event Type GER on Commission Errors (F(2)=6.97, p=.002.

A 2(Grp)X3(EventType) ANOVA revealed no effect of group ($F(1)=0.05$, $p=.819$), no main effect of Event Type GER on Omission Errors ($F(2)=2.69$, $p=.075$. There is also an association of Group with Commission Error Type (*misunderstandings*, *confusions*, or *missing actions*). The ASD group incorrectly reported more *missing actions*($X^2[1,N=31]=5.45$, $p=.020$), but there was no difference between the groups for reports of *misunderstandings*or *confusions*.

Conclusions:

In contrast to previous results, the current study indicates that young children with high-functioning ASD are just as capable as their NT counterparts at identifying script disruptions for common, social events. Additionally, more commission errors were made regarding the restaurant scenario as the ASD sample identified more missing actions that were not explicitly depicted in the script.

88 **205.088** Relationship between Executive Function and Language Skills in Youth with Autism Spectrum Disorder

C. Labonté[1], *E. Gaudet*[2], *L. Trafford*[1], *K. Howard*[1], *R. Del Colle*[3], *V. R. Smith*[2] *and H. M. Brown*[1], *(1)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (2)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (3)University of Alberta, Edmonton, AB, Canada*

Background: One of the most important skill sets for youth to master is executive functioning (EF). Strong EF skills are related to social competence, academic achievement, and positive life outcomes (Center on the Developing Child, 2011). Many EF processes are dependant upon language which plays an integral part in top-down processes that allow for the regulation of thoughts, feelings and behaviour (Vygotsky, 1978; Zelazo, 2015). For example, consider the critical importance of using self-talk to help calm yourself down when you're upset instead of yelling and throwing things. Among typically developing (TD) children, language consistently predicts the development of EF (Faja et al., 2016). However, only two studies have examined this relationship in ASD. Joseph et al. (2005) found no relationship between EF and language concluding that perhaps youth with ASD are not using language to support EF. However, Akbar and colleagues (2013) demonstrated that 62% of the variability in working memory ability was explained by language in their sample of youth with ASD. Therefore, more research into the relationship between EF and language in youth with ASD is necessary.

Objectives: We examined relative impact of language ability to predict variability in EF skills across a sample of youth with ASD.

Methods: Twenty-five youth with ASD, aged 6 to 16 years (M=10 yrs) completed a measure of receptive language, *Peabody Picture Vocabulary Test-Fourth Edition* (PPVT), and a measure of their expressive language skills, Expressive Language Index (ELI) from the *Clinical Evaluation of Language Fundamentals- Fifth Edition*. Set-shifting, working memory and inhibition were each assessed using subtests from the *NIH Toolbox* and *Weschler Intelligence Scale for Children-5th Edition*. Additionally, parents completed the *Behaviour Rating Inventory of Executive Function- Second Edition* as a measure of participants' EF-related behaviour.

Results: To examine how well language ability predicted EF, we created regression models of EF using our language measures as predictors. Our first model explained 61.1% of the variance in our working memory task with ELI making the only unique contribution to the variability in scores. In contrast, our second model predicted 36.2% of the variance in inhibition with PPVT-4 making the only unique contribution. Finally, while the third model explained 20.4% of the variance in our set-shifting task, neither ELI nor PPVT made unique contributions. However, language did not predict EF when the parent-reported measure of EF was used in the model.

Conclusions: Our results lend further support to the hypothesis that language ability predicts EF skills for youth with ASD. This suggests that youth with ASD are capable of using language in service of EF processes. While many students with ASD may not have strong EF skills (Demetriou et al., 2017), these findings suggest that they seem to use language in EF process in the same way that TD kids do. More importantly, this work may suggest that parents, clinicians and educators may need to focus on strengthening the language-based strategies used during EF processes to support the development of these skills.

89 **205.089** Second-Order Joint Attention: Children with Autism Spectrum Disorder Showed Abnormal Eye Movements in Response to Others' Gaze Following

Q. Wang[1], *S. P. Hoi*[1], *C. Song*[1] *and L. Yi*[2], *(1)Peking University, Beijing, China, (2)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background: Considerable empirical evidence shows that children with Autism Spectrum Disorder (ASD) have an intact ability to follow others' gaze direction, which seems to contradict clinical observations that children with ASD have difficulty with joint attention. In real-life, joint attention has an interactive and reciprocal nature and may involve a multi-order process—we don't merely respond passively to others' gazes, but also interpret others' responses to the our own gaze direction and modify our attention accordingly.

Objectives: We propose a multiple-layer concept of joint attention that defines first-order joint attention as attentional responses to others' gazes and second-order joint attention as gaze responses to others' first-order joint attention. In the present study, we focused on the second-order joint attention in children with ASD compared with typically developing (TD) children. Specifically, we aimed to explore how children with and without ASD respond to others' gaze-following when they have initiated joint attention, such as gaze duration on the object followed or not followed by others.

Methods: Twenty-four children with ASD and 24 age- and IQ-matched TD children completed a computer-based gaze-contingent eye-tracking task. In the task, children had to choose one of two objects to look at (first-looked-at object, FLO) and a computerized face would follow children's gazes towards the FLO (congruent condition), unfollows the gazes towards the other object (incongruent condition), or close the eyes (closed-eyes condition). Novel data-driven temporal-course analyses were used to explore how children with ASD and TD children allocated their visual attention according to others' gaze responses. Furthermore, novel data-driven correlation analysis was used to explore whether looking at eyes would influence subsequent looking time on objects the computerized face gazed at.

Results: TD children, but not children with ASD, were sensitive to others' gaze responses, as evidenced by their higher proportional FLO-looking time in the congruent condition than in the incongruent and closed-eyes conditions, and also higher proportional NFLO-looking time in the incongruent condition than in the congruent and closed-eyes conditions. Such sensitivity occurred around 1700 ms after the computerized face shifted its gaze (Figure 1A & 1B). Also, children with ASD looked at eyes less than TD children during 875-1700 ms after the computerized face shifted its gaze (Figure 1C). Furthermore, we found that TD children, but not children with ASD, who looked more at eyes during around 100-1300

ms tended to look more at the object the computerized face gazed towards during around 1500-4000 ms in the incongruent condition (Figure 2).

Conclusions: Our study bridges a significant gap in the literature by examining the second-order joint attention in both children with and without ASD. We found that TD children, but not children with ASD, showed sensitivity to others' gaze responses to their own gaze. The absence of the sensitivity in children with ASD was possibly due to their reduced eye-looking time caused by their diminished social motivation relative to TD children. Our study provides insights into our understanding of abnormal social cognition in the context of ecologically valid social interactions in children with ASD.

90 **205.090** Short-Term Memory Integration in Adults with Autism Spectrum Disorder

M. Ring[1], *B. Guillery-Girard*[2], *P. Quinette*[3], *S. B. Gaigg*[4] *and D. M. Bowler*[5], *(1)Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, (2)Normandie Univ, UNICAEN, PSL Research University, EPHE, INSERM, U1077, CHU de Caen, Neuropsychologie et Imagerie de la Mémoire Humaine, 14000 Caen, France, Caen, France, (3)Inserm—EPHE, Université de Caen-Normandie, Unité E0218, Laboratoire de Neuropsychologie, CHU Côte de Nacre, 14033 Caen Cedex, France, Caen, France, (4)City, University of London, London, United Kingdom, (5)Autism Research Group, City, University of London, London, United Kingdom*

Background: Adults with Autism Spectrum Disorder (ASD) show difficulties in long-term memory, which are assumed to result from altered relational binding (Bowler et al., 2011). Relational binding is the process that forms a coherent episodic representation out of the elements of an experience. Recently, two studies suggested additional difficulties in short-term memory in ASD, when autistic adults were asked to remember the temporal order of the presentation of digits and words (Poirier et al., 2011) or dot locations in a grid (Bowler et al., 2016). However, so far it is not clear how well ASD participants can form associations between letters and grid locations using colour coding. Moreover, patterns of strength and difficulties in short-term and long-term memory in ASD would help elucidate the different brain regions affected in ASD.
Objectives: This task aimed to test 3-way (object, colour, location) short-term memory binding in ASD. Because of their known difficulties with long-term memory binding, it was predicted that ASD adults would show difficulties with short-term memory binding compared to matched TD adults. In addition, it was of interest to investigate the types of errors made by participants.

Methods: Fifty-three ASD and 52 typically developing (TD) participants matched on gender, chronological age (CA; M_{CA} = 43.03), and intelligence quotient (IQ; M_{FIQ} = 111) were tested on a task asking them to memorise the positions of letters in the cells of a grid. The letters were presented in different colours in the centre of the grid and participants were asked to imagine the letter in the grid cell with the cross of the same colour as the letter. For a subgroup of 33 TD and 34 ASD individuals, still well-matched in terms of gender, chronological age (CA; M_{CA} = 43.14), and intelligence quotient (IQ; M_{FIQ} = 113), we investigated which types of errors they made.

Results: ASD individuals showed significantly lower accuracy rates (M = 0.79, SD = 0.16) compared to TD individuals (M = 0.86, SD = 0.14) in forming the letter-location associations via colour coding ($t(103) = 2.55$, $p < .05$, Cohen's d = 0.50). Groups did not differ significantly in terms of the types of errors they made.

Conclusions: This study suggests that 3-way relational binding difficulties also occur in short-term memory in addition to long-term memory in ASD. A direct comparison of short-term memory and long-term memory in ASD is a task for future research. However, the current study suggests that next to the frontal lobes and the medial temporal lobes, specifically the hippocampus, parietal brain regions might also be involved in atypical memory functioning in ASD, given their role in visual short-term memory (Sheremata et al, 2018).

91 **205.091** Similarities and Differences in Cognitive Control to Motivating Cues in Autism and (co-morbid) ADHD

D. J. Bos[1], *E. L. Ajodan*[1], *M. R. Silverman*[1], *B. Silver*[1], *C. Martin*[2], *A. Di Martino*[3] *and R. M. Jones*[4], *(1)Sackler Institute for Developmental Psychobiology, New York, NY, (2)Weill Cornell Medicine, White Plains, NY, (3)The Child Mind Institute, New York, NY, (4)Weill Cornell Medicine, New York, NY*

Background: Previous work has shown that children with autism show a bias in cognitive control to their interests. However, one of the most frequent comorbidities in autism is ADHD, which is associated with attention problems and impulsivity. It is unknown how the presence of ADHD symptoms influences the bias towards specific motivating cues in autism.
Objectives: We investigated similarities and differences in interference of social and non-social cues with cognitive control in children with ADHD and/or ASD, compared to typically developing children. We expected 1) reduced cognitive control towards interests in ASD, irrespective of ADHD comorbidity, and 2) reduced overall cognitive control, specifically to social stimuli, in ADHD.

Methods: 127 children, aged 6-11 years, who had ASD (with/without comorbid ADHD), ADHD, or were typically developing (TD), performed a go-nogo paradigm with social and non-social cues. For the social conditions, participants were presented with happy and calm faces. For the interest conditions, participants chose their favorite (interest) and least favorite hobby/activity (non-interest) from 23 options. There were 5 different runs of go-nogo pairs (blue vs. yellow rectangles, happy vs. calm, calm vs. happy, interests vs. non-interests, non-interests vs. interests). Participants were instructed to press to the target cue (go) when it appeared on screen and not press to the distractor cue (nogo). Using Linear Mixed-Effects models group differences in hit rate, false alarms and the sensitivity index d-prime were tested.

Results: In the non-social condition, there was an interaction effect betweentask condition and diagnostic status on d' ($F_{(4,192)} = 2.9$, $p = .024$). Children with ASD showed reduced cognitive control towards their interests as compared to their own non-interests ($p = .044$) or colored shapes ($p = .003$)(Figure 1A). The presence of comorbid ADHD did not change this pattern in children with autism. Further, typically developing children showed increased cognitive control to colored shapes, compared to interests ($p < .001$) or non-interests ($p < .001$), whereas children with ADHD did not show any differentiation between stimuli (all p's > .05). In the social condition, there was a main effect for task condition ($F_{(2,171)} = 66.0$, $p < .001$)(Figure 1B), where all children performed better to colored shapes, as compared to happy or calm facial expressions (both p's < .001). Latent profile analyses grouped participants in three independent classes, that showed differentiating patterns of performance across condition, regardless of primary diagnosis (Figure 1C&D).

Conclusions: These findings suggest the affective salience of interests interferes with cognitive control in children with ASD, regardless of the presence of comorbid ADHD. Children with ADHD do not show cue-specific sensitivity during cognitive control to non-social cues, but they do show reduced cognitive control to social stimuli, as do children with autism and typically developing children. Future work in this still growing sample will confirm how affective salience drives individual differences in cognitive control in children with ASD and/or ADHD.

92 **205.092** Social Attention and Language in Siblings of Individuals with Autism Spectrum Disorder

E. Landau[1], *K. Nayar*[2], *N. Maltman*[3], *M. Winston*[2], *L. Bush*[4], *G. E. Martin*[5] *and M. Losh*[1], *(1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (3)Northwestern University, Evanston, IL, (4)Northwestern Feinberg School of Medicine, Chicago, IL, (5)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Previous research has demonstrated that individuals with autism spectrum disorder (ASD) exhibit atypical visual attentional patterns that might contribute to the clinical-behavioral features that define ASD (e.g., Frazier et al., 2017). Studies of parents of individuals with ASD have demonstrated subtle differences in gaze patterns (Nayar et al., 2018; English et al., 2017) and social communication (e.g., Landa et al., 1991; Landa et al., 1992; Losh et al., 2008). Differences in attentional strategies evident through eye-tracking methodology might represent a promising avenue for identifying ASD-related endophenotypes (i.e., heritable characteristics that map more closely to underlying biology than the full clinical phenotype). The present study investigated gaze atypicalities as a candidate endophenotype in both individuals with ASD and siblings of individuals with ASD, examining the intersection of visual attention and social communication across two narrative tasks.
Objectives: To examine visual attentional patterns during narration as a potential contributor to social-communication differences in individuals with ASD and their siblings.

Methods: Sixty-three individuals with ASD, 54 siblings of individuals with ASD, and 52 controls completed two narrative tasks presented on an eye tracker: a structured 24-page wordless picture book (PB) task (Mayer, 1969), and an unstructured, more emotionally evocative narrative task using six images from the Thematic Apperception Test (TAT; Murray, 1943). Proportions of fixations to animate and inanimate information were calculated. Emotion, cognitive, and social words during narration were measured using Linguistic Inquiry Word Count (LIWC; Pennebaker et al., 2001) software. Global pragmatic abilities were assessed during a semi-structured conversation using the Pragmatic Rating Scale (PRS; Landa, 1992) or Pragmatic Rating Scale-School Age (Landa, 2011). Analyses controlled for IQ.

Results: Siblings of individuals with ASD allocated more attention to animate stimuli (ps<.05) than individuals with ASD and controls. Siblings also used fewer emotion words than controls. In siblings, greater attention to animate information was associated with less frequent use of emotion and cognitive words (p<.05, r = -.32; p<.05, r = -.28) and more global pragmatic language violations (p<.05, r = .28), while in individuals with ASD, greater attention to animate information was associated with more frequent use of social words (p<.01, r = .41). Analyses of the less structured TAT task are underway, and will be reported in the full presentation.

Conclusions: Results revealed subtle visual attentional differences during narration among siblings, which related to broader narrative and pragmatic differences. Increased gaze to animate information related to poorer narrative and pragmatic skills in siblings, suggesting that siblings may not adequately capitalize on social information to support narrative production. These attentional differences may reflect genetic liability measurable in clinically affected and unaffected individuals. Ongoing work assessing gaze patterns and narration during a less structured task may provide additional insights into the full range of visual attentional differences across contexts and their relationship to social communicative differences in siblings.

93 **205.093** Strengths and Weaknesses of Memory in Autism Revealed By a Meta-Analysis

P. Desaunay[1], *A. Briant*[1], *D. M. Bowler*[2], *M. Ring*[3], *P. Gérardin*[4], *F. Guénolé*[5], *J. M. Baleyte*[6], *F. Eustache*[6], *J. J. Parienti*[7] *and B. Guillery-Girard*[6], *(1)INSERM U1077, CAEN, France, (2)Autism Research Group, City, University of London, London, United Kingdom, (3)Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, (4)FHUPEA, ROUEN, France, (5)Service de Psychiatrie de l'Enfant et de l'Adolescent, CHU de Caen, Caen, France, (6)Normandie Univ, UNICAEN, PSL Research University, EPHE, INSERM, U1077, CHU de Caen, Neuropsychologie et Imagerie de la Mémoire Humaine, 14000 Caen, France, Caen, France, (7)CHU de Caen, CAEN, France*

Background:
The literature on memory in Autism Spectrum Disorder (ASD) shows an inconsistent pattern of results.

Objectives:

To address this variability, we report the first ever meta-analysis of short-term (STM) and long-term (LTM) memory in ASD, evaluating the role of the type of material (verbal, visual, visuospatial, neutral faces), type of memory retrieval (free recall, cued recall and recognition), and the organization of items (serial, associative, semantically related).

Methods:

We included 61 studies, comparing individuals with typical development (TD) and ASD or Asperger syndrome, confirmed by ADI and/or ADOS method for diagnosis, and/or DSM-4, DSM-5, or ICD-10 diagnostic criteria, corresponding to a total of 2788 participants (1373 with and 1415 without ASD). We computed effect sizes (Cohen's d) using RevMan 5.3, and linear regressions using SAS 9.4.

Results:

Results revealed an overall memory decrement in ASD with a small to medium overall effect size (d= -0.42 [-0.52; -0.31], p<.001), with greater difficulties in STM (d= -0.50, [95%CI -0.65;-0.34], p<0.00001, I^2=51%), compared to LTM (d= -0.36, [95%CI -0.49;-0.22], p<0.0001, I^2=38%). Analyses on the type of material identified a relative preservation of verbal LTM (d= -0.15, p=0.09), contrasting with impaired LTM for visual material (d= -0.38, p=0.006) and neutral faces (d= -0.79, p<0.00001) in ASD compared to TD individuals, but any subgroup difference for STM. We found a general free recall impairment compared to cued recall and recognition (LTM, free recall: d= -0.31, p=0.0006, cued recall: d= -0.08, p=0.58, recognition: d= -0.15, p=0.08; STM, free recall: d= -0.56, p<0.00001, recognition: d= -0.33, p=0.07) in ASD compared to TD individuals. We identified diminished serial (d= -0.58, p<.00001) and non-serial STM performance, and associative (d= -0.38, p=0.0005) and non-associative LTM. Regression analyses revealed that memory impairment increased with the ADOS symptoms severity (β= -0.17, p=.014).

Conclusions:

Overall memory difficulties in ASD suggest the involvement of common processes such as executive dysfunction associated with atypical connectivity. Based on neurobiological data in ASD, we suggest that alterations in low and high frequency oscillations may alter the maintenance and rehearsal processes associated with STM storage that may also impact LTM functioning. Dissociation in LTM suggest that intact verbal LTM, mainly conceptually-driven, may rely more on the global preservation of semantic knowledge in ASD, while difficulties in visual LTM may be due to abnormally elevated left-over-right connectivity ratio in ASD supporting a more local processing of visual items. Finally, the general free recall

impairment may emerge from difficulties in adequately searching retrieval cues, associated with executive and electrophysiological specificities, limiting the memory search process. This hypothesis may also account for intact cued recall and recognition, in accordance with the Task Support Hypothesis, and argues in favor of using memory support.

Finally, we suggest that atypical oscillatory activity arising from neurophysiological abnormalities in ASD rather than a specific alteration of a brain region or a memory system may explain this pattern of results. Preserved verbal LTM and supported retrieval constitute important findings for therapists and caregivers of individuals with ASD, providing opportunities for memory rehabilitation.

94 **205.094** Structural Learning in Children with Autism Spectrum Disorder and Reduced Language

C. L. Thomas-Derwent[1], *M. Ring*[2], *S. B. Gaigg*[3] *and D. M. Bowler*[1], *(1)Autism Research Group, City, University of London, London, United Kingdom, (2)Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, (3)City, University of London, London, United Kingdom*

Background: Characteristic memory impairments in Autism Spectrum Disorder (ASD) include free recall of semantically related items (Tager-Flusberg, 1991; Bowler et al., 1997) and recognition of combinations of features (Bowler, Gaigg & Gardiner, 2014). These findings suggest a difficulty with relational binding, which is defined as the ability to process the relations among items and events, and which is mediated by the hippocampus and fronto-hippocampal processes (Opitz, 2010).

Objectives: Previous research has focussed on verbally-able participants with ASD, using verbalisable stimuli (e.g. lists of words or nameable pictures). The current study aimed to measure relational binding using a non-verbal paradigm, to investigate whether the relational memory profile of less verbally-able individuals with ASD is comparable to those with ASD without language impairments. A test of configural learning was adapted, in which hippocampally-lesioned rats showed impairments only when awareness of the structural aspects of the stimuli (e.g. left-right arrangement) was necessary for success (Sanderson et al., 2006). The prediction was that individuals with ASD would display similar patterns of performance as was observed in rats with hippocampal lesions.

Methods: Twenty-five children with ASD and reduced language (AD group) and twenty-six typically-developing children (TD group) were matched on non-verbal ability. One of two configural learning tasks was presented: a biconditional task, in which success was dependent upon awareness of the elements of each stimulus, or a structural task, in which success was dependent upon, in addition, awareness of the spatial arrangement of each stimulus' components. Pairs of stimuli were presented on a touchscreen laptop and participants learnt through onscreen reinforcement which were the correct choices. After the training phase, a test block was presented; this included novel trials consisting of re-paired training stimuli.

Results: Performance during training for both tasks was > 70% for all participants, indicating successful learning of the stimuli. During the test phase of the biconditional task, the TD group performed significantly more accurately overall ($F(1, 23) = 9.02$, $p = .01$, $\eta_p^2 = .28$), although both groups performed significantly above chance for all trials (all *p*s < .05). No overall group difference was found during the test phase of the structural task, and the TD group performed significantly above chance for all trials (*p*s < .05). However, the AD group performed significantly above chance only for the familiar trials ($p = .01$), performing at chance for the novel trials ($p = .08$).

Conclusions: These findings indicate that individuals with ASD and reduced language ability can effectively complete a test of configural learning in which success is solely dependent upon awareness of the elements of the stimuli. They perform less well however, when awareness of the spatial arrangement of the stimuli is also required. These findings align both with earlier work on verbally-able adults with ASD (Ring et al., 2017) and previous research from non-human animals with hippocampal lesions. This therefore strengthens the view that the relational memory difficulties seen in ASD are likely to occur as a result of compromised hippocampal function.

95 **205.095** Successful Imitation of Atypical Biological Kinematics Following Observational Practice in Autism Spectrum Disorders.

N. C. Foster[1,2], *S. J. Bennett*[3], *J. Causer*[1], *D. P. Clowes*[3] *and S. J. Hayes*[4], *(1)Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom, (2)C'MoN, Cognition, Motion and Neuroscience Unit, Istituto Italiano di Tecnologia, Genova, Italy, (3)Research Institute Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom, (4)Department of Psychology and Human Development, Institute of Education,, University College London, London, United Kingdom*

Background: Although sensorimotor processes subserving automatic imitation are operational in autism spectrum disorders (henceforth autism) (Sowden et al., 2016), similar underlying processes function less effectively in a voluntary context where the goal is to observe and imitate biological kinematics performed by a human model (De Myer et al., 1972). This difficulty is suggested to be related to sensorimotor processing activity during direct perception-action matching of biological motion (Stewart et al., 2013). To this end, we used an observational practice (OP) protocol as it enabled the active contribution of the peripheral sensorimotor system during motor execution to be systematically controlled (limited) in an imitation context. Therefore, by controlling this contribution, and based on the automatic imitation work, we expect to show functional movement reproduction of biological kinematics in autism.

Objectives: (1) to examine the direct perception-action matching processes responsible for encoding biological motion during observational practice in autism.

Methods: Twenty autistic (mean age: 25(7); 2 female) and twenty matched non-autistic (mean age: 25(7); 2 female) adults volunteered for the study that was approved by the local ethics committee. Participants completed a 10-trial pre-test where they observed and physically imitated a point-light model displaying typical biological motion with a movement duration of 1700ms. During an observational practice phase, participants performed 30 trials where they only observed a point-light model displaying atypical biological motion with a duration of 1700ms. In a 10-trial post-test, participants were instructed to recall and execute the observed atypical stimulus on each trial. Eye movements were recorded during action-observation. Data for *constant error* (*CE*), *variable error* (*VE*), and *percentage-time-to-peak-hand-velocity* (*tPHV*) were analysed in separate 2 group (autism; control) x 2 phase (pre-test; post-test) mixed design ANOVAs. *Percentage-time-to-peak-smooth-eye-velocity* (*tPSEV*) data was submitted to a 2 group (*autism; control*) x 3 phase (pre-test, early-OP, late-OP) mixed design ANOVA.

Results: Both groups were more accurate at reproducing the observed movement duration following OP (*CE*: $p < 0.05$). However, the movements performed by the autism group were more variable (*VE*: $p < 0.05$). Importantly, both groups represented the observed atypical biological kinematics with *tPHV* ($p < 0.05$) reducing from pre-test (Autism: 41% ± 9; Control: 43% ± 8) to post-test (Autism: 31% ± 7; Control: 30% ± 13). Eye

movement behaviour was similar for both groups ($p > 0.05$).

Conclusions: Although autistic participants performed more variable movements, they imitated the temporal duration of the observed model to a similar level of accuracy as matched-controls. Whilst previous research (Hayes et al., 2016) reported that autistic individuals show attenuated imitation of biological kinematics, the present findings indicated that autistic volunteers observed, encoded and successfully imitated a model displaying atypical biological kinematics following OP. Importantly, this shows that the lower-level perception-action processes responsible for encoding biological kinematics during the action-observation phase of imitation are operational. As the task-specific engagement of the peripheral sensorimotor system was controlled during OP, the aforementioned imitation difficulties in autism are likely to be underpinned by processes engaged to integrate efferent and (re)afferent sensorimotor information during trial-to-trial motor execution.

96 **205.096** The Fractal Structure of Gaze Patterns for Young Children, and Its Relationship to Visual Social Engagement.

R. D. Sifre[1], *I. Stallworthy*[2], *C. Lasch*[2], *T. Smith*[3], *D. Berry*[4] *and J. T. Elison*[5], *(1)Education and Human Development, University of Minnesota, Twin Cities, Minneapolis, MN, (2)Institute of Child Development, University of Minnesota, Minneapolis, MN, (3)Department of Psychological Sciences, Birkbeck, University of London, London, United Kingdom, (4)Institute of Child Development, University of Minnesota, Twin Cities, Minneapolis, MN, (5)University of Minnesota, Minneapolis, MN*

Background: Visual exploration is one of the earliest ways infants learn about the social world. Guided by both bottom-up stimulus properties and top-down motivations, infants' visual attention is thought to be self-organizing and increasingly complex over time. Given the large body of evidence indicating atypical visual social engagement in infants later diagnosed with autism, understanding this self-organization of the attentional system is critical for understanding the early etiology of autism.

We propose that clarifying the *fractal* properties of children's gaze patterns will provide meaningful insights into the emergence of these complex systems. Specifically, complex, non-linear processes often carry organizational structures known as *fractals*—repeated, self-similar patterns across a variety of scales (Mandelbrot, 1977). This mathematical approach has been used to characterize the temporal and spatial structure of adults' gaze behavior (Stephen & Anastas, 2010).

Previously our lab has shown that infants' visual engagement exhibits a fractal structure indicating optimal flexibility when viewing social scenes, and that their gaze becomes more self-organized over developmental time. To follow-up, we investigated whether fractal complexity changes as a function of what infants spontaneously visually engage with onscreen.

Objectives: To investigate how 5- to 36-month-old infants' attention to faces predicts the fractal complexity of their eye-gaze. We hypothesized an Age x Face-looking interaction: for younger infants, attention to the face will be associated with higher fractal complexity. As infants gain competency in visual social engagement, face-looking will be less predictive of fractal complexity.

Methods: Eye-tracking data were collected as participants watched four 20-second movies. Each movie included 3 females performing child-friendly actions, and was divided into 3-4 movement-based segments. Time-series, comprised of amplitude changes between consecutive gaze coordinates, were used for analyses (**Fig. 1a**).

We calculated the fractal complexity of each movie segment for each child (N=137 sessions, 1,076 segments), using detrended fluctuation analysis (DFA; Ihlen et al., 2015). DFA produces a parameter called the Hurst exponent (H), an index of the overall fractal structure of the time-series, on a continuum from *white noise* (more random; ~0.5); to *pink noise* (optimal flexibility; ~0.7-1.0); to *brown noise* (more rigid; ~1.5).

Results: H values for children's gaze behavior were normally distributed (M=0.85, SD=0.10; **Fig.1b**). Preliminary results suggest that in segments during which infants looked at a face, H increased by .05 (p=.004) **(Fig. 2)**. H also increased linearly with age by .002 per month (p=.06), but remained within the pink noise range for all ages. There was a trending Age x Face-looking interaction (p=.09).

Conclusions: Results suggest that, similar to findings in adults, infant gaze patterns exhibit a fractal micro-structure. Moreover, this fractal structure is partially determined by what infants spontaneously fixate on; infants' gaze patterns have higher H values – indicating optimal flexibility – when they look at faces compared to non-social information. This suggests that H values may be used as an index of subjective salience, and could be a critical tool for assessing the subjective value of social information for infants at-risk for ASD. Future work will include longitudinal data to probe within-person changes.

97 **205.097** The Importance of Executive Function for the Social Competence of Boys with ASD

N. Berard[1], ***P. R. Sevigny***[2] *and L. Loutzenhiser*[3], *(1)Saskatchewan Health Authority, Regina, SK, Canada, (2)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (3)Psychology, University of Regina, Regina, SK, Canada*

Background: While many studies have argued that cognitive processes are associated with social functioning deficits in ASD, little research has explicitly examined the associations between executive functioning and social competence. There has been even less comparative research exploring the differences in these associations between neurotypical children and children with ASD.

Objectives: The purpose of this study was two-fold. First, we sought to explore the similarities and differences in performance on standardized executive function (EF) measures between school-aged boys with high functioning autism and a control group of neurotypical boys. Second, we explored the relationship between EF and parent ratings of child social competence.

Methods: A sample of 97 boys, aged 8-13 years and their parent(s) participated in this study. The clinical group consisted of 49 boys with ASD recruited from three provincially-based Autism support programs and a social media forum for parents of children with ASD. Parents provided diagnostic reports or their consent to access health records to confirm diagnoses. The control group consisted of 48 boys without mental health diagnoses or learning disabilities recruited from the local community. Children were administered a measure of intellectual functioning to estimate IQ and 5 standardized EF measures. Parents completed 2 standardized measures assessing their perceptions of their child's social competence.

Results: The control group's performance was statistically better than the ASD group on the IQ estimate, auditory attention, visual working memory, auditory inhibition reaction time and auditory inhibition errors. Unsurprisingly, children in the control group were rated by their parents as significantly more socially competent than children in the ASD group. To examine predictors of parent-rated social competence, first, a single social competence composite was derived by combining the 2 social competence scales. Second, to ensure EF measures were assessed using the

same metric, z-scores were calculated. Hierarchical regression analyses were conducted for the ASD and control group separately. Age and estimated IQ were entered on the first block and the 5 performance based EF scores were entered on the second block. For the control group, the regression was not statistically significant, accounting for only 11% of the variance. In contrast, the regression equation for the ASD group was statistically significant and accounted for 61% of the variance in social competence ratings. Significant predictors of better social competence were younger age, higher auditory attention, higher visual working memory, higher visual inhibition and lower auditory inhibition speed.

Conclusions: Boys with ASD demonstrated significantly poorer executive and social functioning than their similar aged neurotypical peers. For typically developing children, executive function abilities do not predict parent ratings of social competence. However, for boys with ASD, these same EF abilities had a substantial influence on parent perceptions of social competence. Our findings highlight how cognitive differences may underpin observed social impairments in those with high functioning ASD and have potentially broad implications for the conceptualization and implementation of interventions.

98 **205.098** The Mediating Role of Executive Functioning in Problems Behaviors in Autism Spectrum Disorder

A. R. Dallman[1], *D. R. Jones*[2], *C. Harrop*[1] *and B. A. Boyd*[3], *(1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Texas at Dallas, Richardson, TX, (3)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: Increased problem behaviors (such as lethargy and irritability) are commonly observed comorbidities in children with Autism Spectrum Disorder (ASD; Emerson, 1995). In the typically developing population, executive functioning (EF) deficits have been linked to problem behaviors (Hughes & Enor, 2008). It has been proposed that individuals with ASD have a different cognitive profile (Kenworthy et al., 2008). Additionally, prototypical EF deficits in ASD have been linked to alternate brain topographies (Voelbel et al., 2006), suggesting that individuals with ASD may demonstrate unique EF deficits which in turn may lead to increased problem behaviors. However, no studies have investigated the direct relationship between EF deficits, as assessed through validated, researcher administered measures, and problem behaviors.
Objectives: This study examines the relationship between EF, as measured by the NIH-Toolbox Cognition Battery (NIH-TCB), and problem behaviors, as measured by the Aberrant Behavior Checklist (ABC).

Methods: Children with ASD, ages 3-17, years and typically developing (TD) children matched on age are currently being recruited. Data from 143 children and adolescents with ASD (mean age = 9 years; SD= 4 years) and 92 TD controls (mean age = 8 years 5 months; SD = 3 years) is included in this preliminary analysis. TD children demonstrated a significantly higher intelligent quotient (IQ) as indexed via the Stanford-Binet Intelligence Test, Fifth Edition (SB-5; TD mean IQ = 111.6; ASD mean IQ = 91.93; p=.01); therefore, the analysis controlled for IQ. Parents completed the ABC. Four separate path analyses were conducted to test the following hypothesized mediation model: Diagnostic status -> mediator variable (cognitive inhibition and flexibility) -> outcome variable (lethargy or irritability). Both direct and indirect models were tested.

Results: For lethargy, the hypothesized model mediated by cognitive inhibition and direct paths were tested for differences. Both the indirect model (mediated by cognitive inhibition) and the direct model were significant (indirect: Beta= -0.53, p=0.06; direct: Beta= 7.66, p<0.01). However, the hypothesized model mediated by cognitive flexibility was non-significant (indirect: Beta= -0.05, p=0.18). In the case of irritability, the hypothesized model mediated by either cognitive flexibility or inhibition presented non-significant results (p=.40, p=.10, respectively).

Conclusions: These preliminary findings replicate previously observed pathways between cognitive inhibition and problem behaviors (lethargy) in children, while extending these findings to children with ASD using performance-based measures. These findings suggest that interventions targeting EF deficits in cognitive inhibition may also mediate lethargic problem behaviors. However, other problem behaviors such as irritability may not be mediated by EF in the ASD population.

99 **205.099** Underlying Factor Structure of the Brief-2 in a Clinical Sample of Children and Adolescents with ASD

E. Gaudet[1], *C. Labonté*[2], *K. Howard*[2], *L. Trafford*[2], *R. Del Colle*[3], *M. Pohl*[2] *and H. M. Brown*[2], *(1)Educational Psychology, University of Alberta, Edmonton, AB, CANADA, (2)Educational Psychology, University of Alberta, Edmonton, AB, Canada, (3)University of Alberta, Edmonton, AB, Canada*

Background: Children and adolescents with autism spectrum disorder (ASD) often struggle with executive functioning (EF) skills, which can lead to social mistakes and challenges with making decisions, as well as problems with initiating, following, and organizing plans. Given that EF deficits have a significant impact on adaptive functioning of youth with ASD, the measurement of EF skills has become an important component of their neuropsychological assessments. The *Behaviour Rating Inventory of Executive Function* (BRIEF-2) is a standardized questionnaire that assesses the extent to which a child regulates and guides their behaviours in everyday environments (Gioia et al., 2015). The BRIEF-2 contains nine scales that form three indexes (Behavioural Regulation Index, Emotional Regulation Index, and Cognitive Regulation Index) and one composite score (Global Executive Composite). This is different than the previous version of the questionnaire, which contained eight scales across two scales: Behavioural Regulation Index and Metacognition Index. Despite the adoption of the second edition of the BRIEF within current ASD literature and in clinical settings, there has been no published research to date addressing the psychometric properties of the BRIEF-2 for youth with ASD.
Objectives: We investigated the underlying factor structure of the BRIEF-2 in a clinical sample of youth with ASD.

Methods: The BRIEF-2 parent form was completed by parents of 58 youth with ASD (52 males), ages 5 years to 16 years of age (M=9.64 years, SD=3.47). All participants had a community diagnosis of ASD, which was confirmed by parent report of ASD symptomatology on the *Social Responsiveness Scale-2*.

Results: BRIEF-2 scale scores (T-scores) were subjected to principal axis analysis (Direct Oblimin Rotation with Kaiser normalization). The rotated solution found two factors, based on eigenvalues greater than 1 rule and examination of the scree plot (Figure 1), which explained 49.39% of the variance with factor 1 contributing 39.54% and factor 2 contributing 9.86% (see Table 1). Factor 1 primarily contained variables related to cognitive regulation, whereas factor 2 included variables related to emotional and behavioural regulation. As well, self-monitoring (which should load onto behavioural regulation according to BRIEF-2) loaded on both factor 1 and 2.

Conclusions: Despite the fact that the BRIEF-2 manual reports a 3-factor structure for this measure in non-ASD youth, our results revealed a 2-factor structure instead. As such, evidence to support the validity of the three-factor structure of these constructs in youth with ASD was not found. Specifically, the results from our sample did not support distinct emotion regulation and behavioural regulation indices. In other words, our data did not support the underlying theoretical model as described in the BRIEF-2 manual. Therefore, conclusions about cognitive regulation, emotional regulation and behavioural regulation should be made cautiously and differential comparisons of these skills may not be warranted.

100 **205.100** Physiological Responses to Circumscribed Interests, Non-Social and Social Stimuli in Adults with Autism and Neurotypical Controls

C. Singleton[1], *C. Ashwin*[2] *and M. Brosnan*[3], *(1)University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:
Autism has been characterized as reduced social motivation and an enhanced drive towards non-social processing, which includes repetitive behaviours and circumscribed interests. These behaviours may be related to the employment of different mechanisms for processing and orienting towards non-social stimuli (e.g. a car) and social stimuli (e.g. a face). Previous research with a neurotypical (NT) sample has found that a higher number of subclinical autistic-like traits was related to more pronounced physiological responses to non-social stimuli, but not social stimuli or stimuli related to individual circumscribed interests. The greater emotional arousal to items of circumscribed interest were interpreted as reflecting greater salience for these items in people from the general population with higher autism traits, but no study has reported about this in adults diagnosed with autism and matched controls.

Objectives:

To investigate physiological responses to social and non-social stimuli, including stimuli related to participants' individual circumscribed interests in an autism group and neurotypical controls.

Methods:

17 participants with an autism diagnosis (10 male, 7 female) and 16 NT controls (10 male, 6 female) were recruited and were matched by age, sex and education level. Participants viewed 24 images that included 6 social images of human faces and 6 of cartoon faces, and 6 non-social images of various objects (e.g. a train or car) and 6 non-social images relating to each participant's particular interest or hobby. Skin conductance responses (SCR) were recorded as the images were passively viewed. A mean SCR magnitude was calculated for each condition and group differences were explored.

Results:

A Mann-Whitney U test revealed that SCR to the social-faces (U=117, z=1.691, p=.51) social-cartoon (U=104, z=-1.19, p=.26) and non-social (U=117, z=.689, p=.51) conditions were not statistically different between the two groups. However, there were significant differences between autism (Mdn=48.42) and NT (Mdn=47.20) groups in SCR to the non-social of interest condition (U=80, z=-2.023, p=0.043), with the ASD group exhibiting larger responses to images of their individual circumscribed interests than the NT group.

Conclusions:

The findings show a heightened emotional arousal response to items of special interests in adults with autism compared to adult controls, similar to the effects found with nonclinical adults with higher autism traits. However, no group differences were found in emotional arousal response to social stimuli in the adults with autism. These results suggest that items of circumscribed interest have enhanced salience for adults with autism compared to controls, but that social items aren't associated with reduced salience. The findings have implications for social motivation theories of autism.

101 **205.101** 'Intuitive Systemizing' in Autism: Self-Reported Systemizing Drive Is Related to Ability to Solve Logical Problems but Not to Conscious Understanding of Logical Reasoning

C. Singleton[1], *C. Ashwin*[2] *and M. Brosnan*[3], *(1)University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:
Autism Spectrum Disorder (ASD) has been characterised as a drive towards systemizing—understanding and predicting non-social rule-based systems—and away from empathizing—a drive towards social-emotional processing. The Dual Process Theory of Autism proposes that systemizing bias could be explained as a general drive towards deliberative processing, which is characterised as slow, effortful, and conscious, while empathizing is explained by a general bias towards intuitive processing, which is fast, autonomous, effortless and non-conscious. Previous research, however, has found neurological and physiological responses to non-social stimuli in autism that resemble responses to the social in the neurotypical population, indicating there may be an affective component to non-social processing in autism. Enhanced systemizing in autism and enhanced empathizing in the general population may therefore be explained by a bias towards 'intuitive' processing for the non-social and social domains, respectively, with an inherent intuitive bias towards one domain or the other conferring an advantage in understanding and predicting that domain.

Objectives: To investigate self-reported systemizing drive, logical reasoning ability, and reasoning processes in an autistic group and neurotypical (NT) controls.

Methods: 30 participants with autism (24 male, 6 female, ages 18-54, mean 22, SD 3) and 34 neurotypical participants (21 male, 13 female, ages 18-66, mean 22, SD 8.5) completed the Systemizing Quotient-short (SQ) to measure self-reported drive to systemize and the Test of Logical Thinking (TOLT), which includes two scores, one for the correct solution to a logical problem (TOLT Solution score) and one for understanding the correct reasoning process to arrive at the correct solution (TOLT Reasoning score).

Results: Across both groups, SQ was positively correlated with TOLT solution score (r=.386, p=.002) but not with TOLT reasoning score (r=.115, p=.364). The autism group (M=9.97, SD=3.62) performed significantly better than the NT group (M=7.76, SD=2.99) on the TOLT Solution score (t(62)=2.664, p=.01) but there were no significant group differences in TOLT reasoning score (t(62)=.440, p=.661). The mean difference between TOLT Solution and TOLT Reasoning scores for the autism group were almost twice that of the NT group (ASD mean=4.13, SD=4; NT mean=2.21, SD=2; t(62)=2.496, p=.015). The mean difference between TOLT scores was significantly positively correlated with SQ across the whole autism/NT sample (r=.327, p=.008).

Conclusions:

Self-reported systemizing drive is related to ability to solve logical problems. Those with autism performed significantly better than NT controls on the TOLT in terms of getting the answer correct. However, there was no difference in their ability to justify their answers with the correct

reasoning and the autism group were significantly more likely to get the correct answer along with the incorrect reasoning. This is consistent with the proposal that a drive to systemize in autism may confer logical reasoning ability, but not necessarily the ability to consciously understand the logical reasoning that leads to the correct answer. The non-conscious and apparently less effortful logical reasoning in autism is characteristic of intuitive processing within the non-autistic population, raising the possibility that autism can be characterised by 'intuitive systemising' within the Dual Process Theory of Autism.

Poster Session
206 - Communication and Language
5:30 PM - 7:00 PM - Room: 710

102 **206.102** Measuring Early Communication in Classroom Contexts

N. Brady[1], *K. K. Fleming*[2], *K. Muller*[3] *and K. Matthews*[1], *(1)University of Kansas, Lawrence, KS, (2)Life Span Institute, University of Kansas, Lawrence, KS, (3)The University of Kansas, Lawrence, KS*

Background:
There are few standardized tools or strategies designed specifically to measure communication in students with autism who have minimal verbal skills in natural contexts (Kasari et al., 2013; Tager-Flusberg & Kasari, 2013), Standardized or norm referenced assessments often yield scores that are at the floor of norm-referenced assessments. New measures, like the Communication Complexity Scale (CCS; Brady et al., 2012; 2018), may help fill the void of appropriate assessments for this population. The CCS is a 12-point scale that measures pre-linguistic and early-linguistic communication in individuals with autism or intellectual and developmental disabilities who have minimal verbal skills. The CCS can be used to describe students' communication during a standardized play-based assessment and during naturalistic-classroom contexts. This poster presents CCS data from observations in naturally occurring interactions in classroom environments.

Objectives:

1. Present student's CCS scores obtained during classroom observations and standardized play-based assessments.
2. Present CCS reliability results from classroom observations.

Methods:

Participants

- Six students with a diagnosis of autism spectrum disorder and expressive vocabularies of 30 or fewer words, signs, or symbols, between the ages of 5-16 years participated.

Procedure

- A 20-30-minute scripted play-based assessment was administered to each participant. The standardized play-based assessment consists of 12 activities. Research assistants viewed videos of the assessment and assigned a score to the highest communication act produced in each activity. Intentional communication acts were also assigned a function of behavior regulation (BR) or joint attention (JA)
- Each participant was observed during four-to-six, 10-minute naturally occurring classroom contexts, using Noldus Pocket Observer and a time-sampling procedure. During the 12-minute observations, research assistants observed participants for 30-seconds and then had 15-seconds to code the highest communication act that occurred during the 30-second observation period. Function was also recorded for the highest communication act. In addition to BR and JA, we coded Response to Questions or Prompts. We also recorded if particpants' were communicating with teachers or peers.
- Inter-rater reliability during naturalistic classroom observations was computed by comparing scores and functions within each interval, and the average of the highest scores across intervals.
- The following summary scores were derived:

1) Optimal CCS score = average of 3 highest observed communication acts (regardless of function)

2) Typical CCS score = the average of scores from the middle of the distribution

2) Highest BR = the highest communication observed with a BR function

3) Highest JA = the highest communication observed with a JA function

Results:

- Reliability: The range of percent agreement between observers was 56.25 – 100% and the average was 77.08. The Optimal CCS scores from the two observers were all within a point of each other.
- Participants' communication scores varied by context. Most participants' scores were highest in 1:1 interactions and the scripted communication samples.
- For 5/6 participants, almost all communication was directed to adults as opposed to peers.
- Communication to adults was more complex than communication to peers

Conclusions:

- Reliable coding was more difficult during academic instruction.
- Information from the CCS can help identify communication goals and monitor progress.

103 **206.103** Naturalistic Question-Asking in Children with ASD: A Childes Corpus Study

I. G. Leiwant[1], *J. Mann*[1], *S. Arunachalam*[2] *and R. J. Luyster*[1], *(1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)Communicative Sciences and Disorders, New York University, New York, NY*

Background:

Prior research has found that children with ASD often produce fewer questions than their typically developing (TD) peers. Additionally, children with ASD may rely on questions that are restricted in their form and function. A failure to produce questions, especially information seeking queries, may limit potential learning opportunities and may have an impact on multiple developmental domains.

Objectives:

The purpose of this study was to describe the naturalistic questions produced by children with ASD, as compared to their language-matched, TD peers.

Methods:

The Nadig corpus in CHILDES was used, which consists of transcripts of children (ages 1;11 – 6;06) participating in ten minutes of unstructured play with their primary caregiver. To date, transcripts from 12 children (ASD n= 6, TD n=6) have been analyzed for the current project. Groups were matched on mean length of utterance (MLU) and number of word tokens and types; the ASD group was older (ASD: M=63.33 months; TD: M=36.67 months; *p*=.004). A coding scheme captured question form (yes/no vs. wh-) and function (information seeking, non-information seeking); coders were blind to child diagnosis.

Results:

Because of the small size of this pilot sample, descriptive data are provided. The full sample will include 38 children. See Figures 1 and 2.

Number of Questions:

On average, the TD group asked approximately 6.16 questions (SD = 3.57), while the ASD group asked 3 questions (SD = 4.02).

Proportion of Utterances that are Questions:

Questions made up .04 (SD = .05) of the total utterances of children with ASD, while .06 (SD = .03) were questions for the TD group.

Form of Questions:

Proportion variables were utilized to calculate the respective reliance on yes/no vs. wh-questions; .58 (SD = .42) of questions posed by children with ASD were yes/no questions; and .42 (SD = .41) were wh-questions.

In the TD group, .67 (SD = .23) of queries produced were yes/no questions and .29 (SD = .18) were wh-questions.

Function of Questions:

Proportion variables were employed to determine the usage of questions to seek information (vs. for instance, permission or clarification). Information seeking questions comprised .83 (SD =.21) of questions posed by children with ASD, while for the TD group, .67 (SD= .23) of questions were information seeking.

Conclusions:

Findings demonstrated that children with ASD produce fewer questions than their TD peers. This suggests that children with ASD may evoke fewer learning opportunities from their conversational partners. However, frequency of questions appears to be the sole question-asking deficit for children with ASD. The proportion of utterances that are questions were similar across both groups. Proportionally, children with ASD posed slightly more information seeking and wh-questions than their TD peers. These results are inconsistent with prior research, which suggests that the questions posed by children with ASD are often repetitive and non-functional, limited in their form and function (e.g., Hurtig, Ensrud & Tomblin, 1982; Tager-Flusberg, 1994). The results of this study offer further insight into the naturalistic question-asking behaviors of children with ASD, which may have implications for question-asking interventions.

104 **206.104** Nonverbal Communication and Social Imitation Skills in Children with Autism Spectrum Disorder

L. M. Gies[1], *K. M. Walton*[2] *and A. R. Borowy*[2], *(1)The Ohio State University, Columbus, OH, (2)Nisonger Center, The Ohio State University, Columbus, OH*

Background: Autism spectrum disorder (ASD) is a developmental disorder characterized by communication problems and repetitive movements (American Psychiatric Association, 2013). People with ASD demonstrate stress (Miller & Seligman, 1975) and fear (Maier & Watkins, 1998) in uncontrollable social situations. In these situations, people with ASD typically withdraw themselves, allowing learned helplessness and peer rejection to intensify communication problems (Seligman, 1975). Training in nonverbal communication skills, such as joint attention, will strengthen communicative imitation. Imitation is a major component of social interaction. Building imitation skills in children with ASD will ultimately contribute to their ability to interact with other people and form relationships. By identifying which skill is most predictive of communication gains during treatment, clinicians would have adequate evidence as to which treatment may be the best fit for children with varying severities of ASD.

Objectives: The primary aim of this study was to determine whether pre-existing nonverbal communication skills provided a strong foundation for social imitation skills. Specifically, researchers examined whether better response to joint attention at baseline was associated with greater improvement on imitation assessments following ten weeks of play-based treatment focused on building social imitation skills.

Methods: Young children with ASD (N=10) participated in videotaped recordings of the Early Social Communication Scales (ESCS), as well as two imitation assessments—the Motor Imitation Scale (MIS) and both the object and gestural forms of the Unstructured Imitation Assessment (UIA). Children also received ten weeks of twice weekly Reciprocal Imitation Training, a naturalistic developmental behavior intervention focused on building social imitation skills. Responses to proximal and distal pointing were coded from videotaped ESCS assessments. Percentage of models correctly imitated were scored from the MIS and the UIA. The ESCS data was utilized to predict change in imitation using regression analysis of the MIS and UIA before and after therapy.

Results: Regression analyses indicated that child responses to proximal bids for joint attention (examiner pointing to a picture in a book) were

related to change both in MIS scores and UIA object imitation scores, after controlling for imitation score at intake. Interestingly, responses to distal bids for joint attention (examiner pointing to a poster on the wall) were not predictive of change in imitation over time. In proximal responses, the object is closer to the child's line of sight and is noticed more often by children with ASD than a gesture referencing an object in the distance.

Conclusions: The results of this study develop better understanding of the relationship between reciprocal joint attention and social imitation. Having a stronger foundation of joint attention skills, particularly responses to joint attention, was associated with more improvement in imitation during a short-term, play-based intervention. Future work should examine this relationship in a larger sample of children to better understand which children may benefit most from imitation-based therapies such as Reciprocal Imitation Training.

105 **206.105** Online Processing of Svo Word Order in Monolingual- and Bilingual-Exposed Chinese Preschool Children with Autism Spectrum Disorder

J. Mo[1] *and Y. E. Su*[2]*, (1)Child Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China, (2)Childa Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China*

Background: Previous studies in monolingual-exposed children with autism spectrum disorder (ASD) have witnessed their intact knowledge to comprehend Subject-Verb-Object (SVO) sentences in English or Chinese (Swensen et al., 2007; Zhou et al., 2017; cf. Su & Naigles, 2018). Moreover, Reetzke et al. (2015) and Dai et al. (2017) reported equivalent general language abilities in bilingual-exposed children with ASD via standardized scales. However, in oral format, dialects were differentiated from Mandarin for their syntactic differences (Reetzke et al., 2015). Therefore, a refined investigation needs to be conducted on the understanding of SVO word order in Chinese bilingual-exposed children with ASD.
Objectives: Using the Intermodal Preferential Looking, this study attempts to examine early knowledge of SVO word order in bilingual children with ASD exposed to Mandarin and dialect, compared with monolingual peers merely exposed to Mandarin.

Methods: 28 preschool children with ASD in Hunan province of China were recruited to be categorized into 2 groups, i.e., monolingually exposed children with ASD (ME, N=14) and bilingually exposed children with ASD (BE, N=14), well-matched on **age** (AGE=44.21±5.90 vs. 46.64±8.04 months), **autistic behavior scores** (ABC=63.79±20.22 vs. 66.14±18.65), **vocabulary production size** (PCDI=297.50±311.95 vs. 260.29±217.89 words) and **syntactic complexity scores** (MLU=2.11±2.04 vs. 2.68±2.13), all ps>.05, Coh's ds<0.35. Children listened to simple reversible SVO sentences paired with two visual scenes, only one of which matched the test stimuli, e.g., distinguishing between 'the bird pushing the horse' and 'the horse pushing the bird'.

Results: A repeated measure analysis of variance (2 groups×5 verbs×2 trials) only yielded **main effect of trial** $F(1, 10)=5.42$, $p=.04$, $\eta^2=.35$. One-tailed T-tests revealed that children with ASD in both groups exhibited their **sensitivity to SVO word order**, by looking longer at the matching screen during test trials than control trials (ME: Test: 52.98%±14.87% vs. Control: 45.83%±10.35%, $t(13)=1.93$, $p=.04$; BE: Test: 52.44%±9.84% vs. Control: 43.60%±11.86%, $t(13)=2.54$, $p=.01$). However, two groups differed in their optimal performance shown either in the 2nd half (ME: 2ndTest: 56.82%±16.85% vs. Control: 45.83%±10.35%, $t(13)=2.66$, $p=.01$) or 1st half (BE: 1stTest: 54.12%±10.13% vs. Control: 43.60±11.86%, $t(13)=3.05$, $p<.01$) of test trials. **Time course** confirmed that the ME group showed a preference of looking at the matching scene only after the object NP was presented (fig. 1), while the BE group could give an immediate response with the presence of the subject NP (fig. 2). **Correlation** data revealed that monolingual-exposed children with higher severity of autism were slower to locate matching screens ($r=.55$, $p=.02$). Bilingual-exposed children with larger vocabulary production size looked more to the match during the 2nd half of test trials ($r=.530$, $p=.03$).

Conclusions: Therefore, grammatical strength in children with ASD won't be challenged with bilingual exposure. Both monolingual- and bilingual-exposed children with ASD succeed in mapping the subject and object noun phrases in SVO sentences with the thematic agent and patient roles around 4 years old, corroborating "the universal constraint on the form-meaning mapping" (Franke et al., 2013). Moreover, the efficiency of online processing in children with ASD is affected by multiple factors including language environment, severity of autism and vocabulary size.

106 **206.106** Parent-Child Interactions in School-Age Children with Autism Spectrum Disorder, Fragile X Syndrome, and Down Syndrome

L. Bush[1]*, E. Landau*[2]*, G. E. Martin*[3] *and M. Losh*[2]*, (1)Northwestern Feinberg School of Medicine, Chicago, IL, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Difficulties in pragmatic language are a hallmark of autism spectrum disorder (ASD), and are also prominent in other neurodevelopmental disorders showing phenotypic and genetic overlap with ASD, such as fragile X syndrome (FXS) (e.g., Roberts et al., 2007). High rates of noncontingent and perseverative language have been reported in both idiopathic and syndromic ASD (FXS-ASD), though differences were observed as well (Martin et al., 2018). Understanding the impact of these difficulties across communicative contexts and conversational partners has important implications for illuminating potentially shared etiologic pathways and informing targeted interventions. This study examined pragmatic profiles of these groups during parent-child interactions to characterize both child and parent contributions to communication, including parental contingency and responsiveness, known to impact language outcomes (Haebig, McDuffie, Weismer, 2013; Siller & Sigman, 2008).
Objectives: Pragmatic skills including contingency, perseveration, initiations, and responsiveness were examined during parent-child interactions in school-aged children with ASD, FXS, Down syndrome (DS), and typical development (TD) and their parents.

Methods: Participants included boys with ASD (n=34), FXS-ASD (n=41), FXS-Only (FXS-O) (n=11), DS (n=22) and TD (n=22). Parent-child language samples from a five-minute dyadic free-play interaction were transcribed verbatim and analyzed using a detailed hand-coding system (Roberts et al., 2007). Language samples were examined for discrete pragmatic skills described above and parent strategies (e.g., use of scaffolds, praise, narration), which were considered in relation to parental features of the Broad Autism Phenotype (BAP). Nonverbal mental age, receptive and expressive vocabulary, and mean length of utterance were controlled in analyses.

Results: Boys with ASD and FXS-ASD were less contingent than all other groups (ps<.01). Boys with ASD were less responsive during conversation compared to all other groups, including FXS-ASD (ps<.02). Boys with FXS-ASD were more perseverative than all other groups (ps<.01). No significant differences emerged in initiations (ps>.11). Similarly, parents of children with ASD and FXS-ASD were less contingent compared to parents of children with DS (ps<.06) and TD (ps<.08), whereas only parents of children with FXS-ASD differed from the FXS-O parent group (p=.01). Parents of individuals with FXS-ASD were more perseverative than parents of children with DS and TD (ps<.02), though they did not differ significantly from the ASD or FXS-O groups (ps>.28). No significant differences in responsiveness or initiations emerged (ps>.12). Finally, parents of children with ASD

used marginally fewer parent strategies (e.g., scaffolds, narration) compared to parents of children with DS (p=.05), which was related to BAP features in the ASD parent group (p<.05).

Conclusions: Consistent with prior literature examining discrete pragmatic skills during examiner-child interactions (Martin et al., 2018), results highlight both areas of overlap and divergence across idiopathic and syndromic ASD. Interestingly, similar profiles emerged in parents, which may highlight the ways in which parental language style can be bidirectionally influenced by child pragmatics, as well as BAP status, during dyadic interactions. Overall, results of this study have the potential to inform pragmatic language interventions that are aimed at improving dyadic contingency in school-age children with ASD.

107 **206.107** Parental Linguistic Alignment in Conversations with Children with ASD and TD Children

R. Fusaroli[1], *E. Weed*[1], *D. A. Fein*[2] *and L. R. Naigles*[2], *(1)Aarhus University, Aarhus, Denmark, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Linguistic alignment is the tendency to re-use an interlocutor's lexical choices ("mommy, give me the *giraffe*", "is that a *giraffe*?"), syntax ("*the giraffe has fallen*", "yes and *the elephant has gone* to help her") and semantics (topic continuation). It arguably facilitates the establishment of common ground and rapport, and fosters more successful social interactions (Dale et al 2013). While the ability to align in children with ASD has been investigated, the way in which parents align to and scaffold their children's linguistic production is unexplored, although it may have important consequences for the social and linguistic development of the children. For instance, parents might mark joint attention, and engagement, as well as give feedback and further elaboration to their child's utterances.

Objectives: We investigate whether i) parents consistently align their lexical, syntactic and semantic choices to their children's utterances; and ii) this tendency is modulated by the child's clinical and cognitive features.

Methods: We analyzed spontaneous speech in 67 parent-child dyads from a longitudinal corpus (6 visits over 2 years), consisting of 30 minutes of play activities. We included 32 children diagnosed with ASD (mean age at recruitment = 32.76 months and 35 linguistically matched TD children (mean age at recruitment = 20.27 months). Alignment was calculated as cosine similarity between successive conversational turns (parent following child). Lexical alignment was based on lemmatized words, syntactic alignment on 2-grams of part-of-speech tags, and semantic alignment on Word2Vec representations of the corpus (Duran et al 2019). We first contrasted parental alignment in actual conversations with that in surrogate pairs formed by a parent and a child from two different conversations and found consistent alignment above baseline. We used Bayesian multilevel zero-and-one-inflated-beta regression models to account in the same model for rate of alignment, level of alignment when aligning, and exact repetitions (the latter controlled for, but not reported here). The models assessed alignment as a function of diagnosis, visit, Vineland Socialization, Mullen Expressive Language (EL) and Visual Reception (VR) at first visit. We controlled for effects of child MLU.

Results: The Table displays the full findings. Propensity to align (rate) and level of alignment (mu) were lower in parents of children with ASD. As the children grow older, parents increase their propensity to align over time (fewer non-aligned turns), but not their average level of alignment (stable for lexical and semantic alignment, decreasing for syntactic alignment). Parental alignment was higher for children with higher socialization (lexical), EL (all) and VR (semantics). For children with ASD, higher EL reduced the difference (interaction) in parental lexical and semantic alignment from TD children, but it increased the difference in syntactic alignment; higher VR reduced the difference in lower semantic alignment.

Conclusions: Parental alignment is modulated by the child's clinical and cognitive features. Alignment is generally higher for TD and generally children with higher cognitive abilities. Crucially, we observe different patterns for rate and level of alignment, which were not previously separated in studies of alignment. Research is needed to further explore their separate implications.

108 **206.108** Perceptual and Acoustic Measures of Prosody in Individuals with Autism Spectrum Disorder and First-Degree Relatives

S. P. Patel[1], *E. Landau*[1], *C. Rayburn*[1], *G. E. Martin*[2], *G. Dillman*[1], *S. Elahi*[1] *and M. Losh*[1], *(1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Communication Sciences and Disorders, St. John's University, Staten Island, NY*

Background: Impairments in prosody (e.g., intonation, stress) can be among the most notable characteristics of individuals with autism spectrum disorder (ASD), and can significantly impact communicative interactions (Mesibov, 1992; VanBourgonien & Woods, 1992). Subtle differences in prosody have also been reported in parents of individuals with ASD, suggesting that familial characterization of prosody may help to highlight genetic influence on components of language impacted in ASD. While prior studies of prosody in ASD have used the *Profiling Elements of Prosody in Speech-Communication* (*PEPS-C*) to gather perceptual ratings of prosody and some have incorporated acoustic measures alongside these ratings, comprehensive perceptual and acoustic investigation of how specific prosodic abilities (e.g., contrastive stress, lexical stress) differ in individuals with ASD and their parents are needed to clarify key domains contributing to perception of atypical prosody in ASD.

Objectives: To assess perceptual and acoustic measurements of prosody in individuals with ASD and their parents.

Methods: Individuals with ASD (n=26), their parents (n= 43), and respective control groups (n=16 ASD controls; n=30 parent controls) completed the *PEPS-C*, which was rated by blinded coders. Responses to the expressive subtests of the *PEPS-C* from a subset of participants (ASD n=5; proband controls n=6; ASD parents n=14; parent controls n=10) were further characterized with acoustic analysis using Praat (Boersma, 2001) to obtain measures of mean fundamental frequency (f_0), standard deviation (SD) of f_0 and f_0 range, both measures of f_0 variability (acoustic analysis of data from the full sample is ongoing). Additionally, correlational analyses were conducted to examine relationships between these measures.

Results: Individuals with ASD and their parents exhibited poorer prosodic imitation, lexical stress expression, and contrastive stress expression (*ps*<.05). Individuals with ASD also demonstrated significantly greater atypicalities in phrase stress expression (e.g., "I saw a *blue bird*" vs. "I saw a *bluebird*") compared to controls, and this difference was marginal between the parent groups, with the ASD parent group demonstrating greater atypicalities (*p*=.05). Of the seven receptive subtests, individuals with ASD performed more poorly than controls only in their understanding of contrastive stress (*p*<.01). Acoustic analyses did not reveal significant differences in the ASD (*ps*>.67) or parent groups (*ps*>.61). Decreased f_0 range was associated with ratings of poorer contrastive stress ability in ASD parents (*r*= .60, *p*=.04).

Conclusions: Individuals with ASD and their parents demonstrated greater prosodic atypicalities across several domains of the *PEPS-C* based on perceptual ratings. However, consistent with prior work, these differences were not readily apparent based on acoustic measures of prosody (Diehl et al., 2013), although associations in the ASD parent group suggest that perceptual differences may be related to decreased f_0 variability.

The large overlap between subtests in which individuals with ASD and their parents differed from their respective control groups highlights the domains of imitation, lexical stress, and contrastive stress as potentially key areas contributing to overall perception of prosodic atypicalities during conversational interactions. Ongoing analyses including a larger sample size will further investigate acoustic differences and relationships with perceptual ratings of prosody in all groups.

109 **206.109** Phonological Factors Underlying Performance on a Multi-Lingual Non-Word Repetition (ML-NWR) Task

H. Goad[1], *F. Li*[2], *A. M. Gonzalez Barrero*[3] *and A. Nadig*[2], *(1)Department of Linguistics, McGill University, Montreal, QC, Canada, (2)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada, (3)McGill University, Montreal, QC, CANADA*

Background:

Performance on non-word repetition (NWR) tasks is commonly used as a clinical marker of language impairment (LI) (Chiat, 2015). To achieve a range of complexity, available tools sometimes compromise wordlikeness and/or do not control phonological factors across stimuli (Edwards et al., 2004; dos Santos & Ferré, 2018). For example, in the English-medium CNRep (Gathercole et al., 1994), half the words are 4-5 syllables long while the average for English is 2.72 (Cutler et al., 2004); further, presence/absence of complex onsets and codas and their position are not controlled, although these factors can affect acquisition for typically-developing children (Fikkert, 1994).

Objectives:

A growing number of North American children are bilingual in English-Spanish, English-French, or French-Spanish. To appropriately diagnose LI in these populations, we designed the Multi-lingual Non-word Repetition (ML-NWR) Task. The stimuli in each language control for wordlikeness and various types of phonological complexity, yet are highly similar across languages to facilitate cross-language comparison.

Methods:

We created 27 non-words 2-4 syllables in length (Table 1). For each word length, syllable structure complexity was controlled: all syllables were open, initial syllables were closed, or final syllables were closed. Segmental shape was controlled within and across syllables. Stress location followed regular rules for each language.

ML-NWR data was analyzed from 88 children, aged 5-10. Their dominant language (L1) was English or French; some were bilingual (L2s = French, English, or Spanish). 36 children were diagnosed as ASD, 18 of whom additionally had LI. 52 were typically developing. Children in all diagnostic groups (ASD-LI, ASD, TYP) were similar in age, nonverbal IQ, and SES; further, ASD-LI and ASD groups did not differ in symptom severity on the Social Communication Questionnaire.

Results:

We focus on performance differences in children's L1 related to syllable shape (L2 analyses are on-going). Performance on open versus closed syllables was similar across language and diagnostic groups. However, differences were observed depending on position of closed syllable—final versus non-final (Figure 1). For both languages, there were main effects of diagnostic group and position. For French, but not English, there was a significant group-by-position interaction. Planned comparisons show that the ASD-LI group performed significantly worse than ASD on *final* closed syllables in English; and on *non-final* closed syllables in French.

English and French differ in stress location: the most prominent syllable is final in French (Delattre, 1939) and non-final in English (Chomsky & Halle, 1968). Consequently, in our French stimuli, final closed syllables were stressed while non-final closed syllables were not; in English, the opposite pattern held. In short, in the ML-NWR, stress facilitated the production of complex syllables, likely because stressed syllables have greater duration.

Conclusions:

Our findings arise from cross-language differences in stress location and thereby highlight the need to consider several linguistic factors in the design and scoring of assessment tools. Although word length and syllable complexity are typically varied across stimuli in existing NWR tasks, location of stress relative to syllable complexity is not controlled and scoring only considers percent phonemes correct, regardless of stimulus shape.

110 **206.110** Pragmatic Language Abilities in Siblings of Individuals with ASD

S. Crawford[1], *K. Nayar*[2], *L. Bush*[3], *G. E. Martin*[4] *and M. Losh*[5], *(1)Communication Sciences and Disorders, Northwestern University, Chicago, IL, (2)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (3)Northwestern Feinberg School of Medicine, Chicago, IL, (4)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (5)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Pragmatic language impairment is a defining feature of autism spectrum disorder (ASD). More subtle pragmatic differences also constitute a core feature of the broad autism phenotype in clinically unaffected relatives (BAP; Landa, 1991, 1992; Losh et al., 2008; Piven et al., 1997). Whereas pragmatic abilities have been studied extensively in parents through both direct assessment and questionnaire, studies of pragmatic skills in siblings have been more limited, relying on parent report and/or focused on early developmental periods when more complex pragmatic skills have not yet emerged. This study assessed pragmatic language abilities in school-age and young adult siblings of individuals with ASD, using direct assessment of conversational interactions.

Objectives: To characterize pragmatic language features of the BAP in siblings of individuals with ASD, and explore how pragmatic abilities aggregate within families.

Methods: Participants included 117 individuals with ASD, 43 siblings, and 46 typically developing controls. Pragmatic language abilities were assessed using the Pragmatic Rating Scale-School Age (PRS-SA; Landa, 2011) during conversational interactions from the Autism Diagnostic Observation Schedule (ADOS; Lord, 2001) or ADOS-2 (Lord, 2012). The PRS-SA is comprised of items that tap five sub-domains of pragmatic skill: presupposition/theory of mind, discourse management, speech and language behaviors, suprasegmental characteristics (e.g., intonation, rate of speech, volume, and rhythm; which are important for mediating expression of communicative intent), and non-verbal communicative behaviors. ANCOVAs were conducted to examine group differences. Sibling correlations were also explored. Analyses controlled for age and IQ.

Results: A stepwise pattern emerged across all domains of the PRS-SA, where individuals with ASD presented with the greatest pragmatic

language impairment, followed by siblings, and controls showing lowest rates of pragmatic violations. Whereas individuals with ASD exhibited greater impairment than both sibling and control groups across all domains (*p*s<.001), siblings differed from controls only in the suprasegmental domain (*p*=.031). Additionally, pragmatic language ability was positively correlated between the ASD and sibling groups (*r*=.27, *p*=.03), with correlations driven by associations in the suprasegmental domain (*r*=.31, *p*=.01).

Conclusions: Findings revealed differences in suprasegmental aspects of speech among siblings of individuals with ASD. Within-family associations further suggest that suprasegmentals may comprise a key feature of the pragmatic-related component of the BAP in siblings. This contrasts with studies of the BAP in parents, where more widespread pragmatic difficulties have been observed. However, studies of parents included more naturalistic conversational tasks, which highlights the importance of extending the current study to contexts beyond the ADOS. Finally, results emphasize the need for further exploration into suprasegmental differences observed in siblings. Future studies should investigate suprasegmental use in siblings objectively through acoustic analysis which may reveal key aspects of pragmatic language impacted by genetic liability to ASD.

111 **206.111** Pragmatic Language Competence of School-Aged Children with Autism in Peer Conversations

Y. Li[1], *H. Zhu*[1], *Y. Zou*[1], *Y. Ji*[1], *Y. Zhang*[1], *W. Cao*[2], *Y. Wang*[1] *and X. Zou*[1], *(1)Child Developmental & Behavioral Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (2)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China*

Background: These years more and more verbally fluent children with autism spectrum disorders (ASD) are able to adapt into the mainstream education and develop peer relationships in their school age. Researches show that these children may still present some residual deficits, and the pragmatic language competence is one of them. However, little is known about these subtle difference from a quantitative and detailed aspect. Most of the standard tests of pragmatic language (parent/teacher report scales or checklists and structured evaluation) find that these pragmatic deficits may be the ability of turn-taking and autistic-specific speech acts. Since the pragmatic impairments sometimes only present in real-life social interactions, we set up a natural environment and explore children's pragmatic language competence during peer conversations between typically-developed (TD) children and these children with ASD, which provides a new perspective in detecting and evaluating pragmatic language ability.

Objectives: This study aims to compare the communication acts, conversational skills and autistic-specific speech acts of these mandarin-speaking children with ASD and TD children during peer talk.

Methods: 13 ASD (mean age 9.15±1.34, IQ: 92.38±13.15) and 13 age-matched and IQ-matched TD children (mean age:9.08±1.65, IQ: 98.62±11.63) participated in this study. We used a strategic card game to induce the peer talk between the children with ASD and his/her TD friend/cousin （age difference less than 2 years old). Then we coded and analyzed the 10 minutes' conversation by CHILDES (Child Language Data Exchange System). The coding system we used in communication acts is Inventory of Communicative Acts-Abridged (INCA-A). The coding aspects of conversation skills includes turn-taking, initiation, continuation (reply and expand), discontinuity and repair. Furthermore, we defined the special autistic-style speech into five types according to the ASD linguistic symptoms. The Chi-Squared Test and t test are used to test the significance of the difference and the Pearson correlation coefficient was used to analyze the clinical significance of the pragmatic language competence.

Results: The results suggested that compared to their own TD peer, children with ASD showed significantly less sum of conversation continuation (ASD:37.46±12.96, TD:66.69±23.45, p=0.002), especially less expand in his/her turn (ASD:16.38±8.69, TD:40.54±23.44, p=0.02), less ratio of conversation continuation to initiation (ASD:0.89±0.41, TD:1.63±0.64, p=0.004), more autistic-style speech (sum: p=0.005, type: p=0.002) and more discontinuity(p=0.02). The difference in communication acts, sum of turns, and conversational repair were not significant. Strong correlation was found between total score of ADOS and some pragmatic indications, such as sum of effective utterance (r=-0.61, p=0.02), type of autistic-style speech (r=0.70, p=0.007) and sum of conversation initiation (r=0.63, p=0.02).

Conclusions: The results of the present study gave new evidence about the pragmatic language competence of children with high functioning ASD. They tend to express more actively in changing topics and initiating turns, but their performance of continuation of a certain topic, clarifying messages and adding more related information in their own speech turns was not as good as their TD peers, which cannot be reflected from their ADOS score and appear to be more difficult to improve even if they have adapted to mainstream education.

112 **206.112** Pragmatic Language Outcomes Following Social Communication Intervention for Children with High Functioning Autism Spectrum Disorder or Social Pragmatic Communication Disorder: Evaluation of a Novel Preference-Based Measure

ABSTRACT WITHDRAWN

Background: Children with High-Functioning Autism Spectrum Disorder (HFASD) have significant, heterogeneous pragmatic (social use of language) deficits and may have structural language impairments (Landa 2000, Volden et al 2009). Children with Social (Pragmatic) Communication Disorder (SPCD) have similar communication difficulties but do not meet diagnostic criteria for ASD (DSMV). Pragmatic/language deficits have long-term effects on employment success and mental health (Howlin et al 2004, Mayes & Calhoun 2011). Speech-language therapy (SLT) may prevent adverse consequences in both groups but there are few trials of pragmatics intervention (Gerber et al 2012). A manualized intervention, the Social Communication Intervention Programme (SCIP) (Adams & Gaile 2015) provides relevant content but estimates of changes in pragmatics are required for trial purposes. Given pragmatics heterogeneity at baseline, a way forward is to adopt an individualized approach to language/pragmatics therapy planning and a preference-based outcome measure.

Objectives: To study the variability of a modified goal–attainment scaling method (SCIP- GAS) as primary endpoint to SCIP intervention for children with HFASD or SPCD; to study the relationship between parent outcome commentaries and SCIP-GAS scores.

Methods: 15 UK SLTs identified twenty children with pragmatics/language needs. Inclusion: aged 6-11; social communication difficulties on pragmatics checklist (Adams et al 2012); normal range non-verbal IQ. Baseline: Children's Communication Checklist-2 (CCC-2) (Bishop 2003); Social Language Development Test (SLDT) (Bowers et al 2017) (secondary outcome); Module 3 ADOS-2 (Lord et al 2012). A researcher independent of the intervention completed testing. SLTs received SCIP training and six hours of supervision from a Research SLT (RSLT). Children received 20 direct SCIP therapy sessions. Primary endpoint SCIP-GAS: At Time 1 (T1) parents provided three prioritized communication goals. Expected steps in each goal were defined by RSLT at T1. After intervention (T2) parents and SLTs (independently) rated each goal compared to T1 baseline ability on a

scale of -1 (got worse) to + 5 (greatly exceeded). Parents provided a commentary on outcomes. Two RSLTs compared parent comments with SCIP-GAS scores to derive guidance about clinical significance for a future trial.

Results: All children met criteria for communication impairment on CCC-2; 11 met ADOS criteria for ASD; 9 were defined as SPCD. All children except one progressed on SCIP-GAS parent outcomes (mean 6.8, SD 3.1). All children progressed on practitioner SCIP-GAS ratings (mean 8.6, SD 2.2). Clinical significance was associated with SCIP-GAS scores of 6-9; high clinical significance with scores above 9. SLDT: Making Inferences scores were significantly higher at T2; there were no T1-T2 differences on Multiple Interpretations or Supporting Peers.

Conclusions: A preference-based pragmatics measure showed feasibility as an outcome following social communication intervention for children who have HFASD and SPCD. Estimates of sample size and clinical significance for a full trial have been made.

113 **206.113** Preschool Language and Cognitive Predictors of Middle Childhood Reading Abilities in ASD and Typically Developing Children

N. S. McIntyre[1], *M. Solomon*[2], *C. W. Nordahl*[3] *and B. Heath*[3], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: A growing body of research has demonstrated that reading abilities in individuals with autism spectrum disorder (ASD) and no intellectual disability (ID) are heterogeneous and that basic reading skills such as rate, accuracy and fluency may display greater developmental dissociation from higher order reading comprehension skills in ASD than in those with typical development (TD). Variability in reading skills has been shown to relate to concurrent oral language skills. However, little is known about the developmental trajectory of this association.
Objectives: The purpose of the current study was to examine preschool language and cognitive predictors of reading achievement more than eight years later, in middle childhood, in a sample of children with ASD compared to those with TD.

Methods: Participants were part of the Autism Phenome Project (APP) longitudinal cohort, and included children with ASD (*N*=32) and TD (*N*=43) without ID (middle childhood FIQ range 70-140), who were first assessed at ages 24-54 months (mean age=36.99 months, *SD*=5.73 months) and then followed-up in middle childhood at ages 115-163 months (mean age=138.26 months, *SD*=9.75 months). Time 1 assessments: IQ, Mullen Scales of Learning (MSEL); receptive vocabulary, Peabody Picture Vocabulary Test (PPVT); and expressive vocabulary, Expressive One Word Picture Vocabulary Test (EOPVT). Middle childhood assessments: IQ, Differential Ability Scales, Second Edition (DAS-II); reading rate, accuracy, fluency, and comprehension, Gray Oral Reading Test, Fifth Edition (GORT-5).

Results: While the ASD group had average middle childhood FIQ (*M*=96.06, *SD*=15.10), they scored significantly lower than TD, therefore ANCOVA's controlling for FIQ were conducted on all reading variables. GORT-5 reading rate, accuracy and fluency were not significantly different between ASD and TD groups. However, ASD scored significantly lower than TD on reading comprehension (f=9.19, p=.003). Separate hierarchical linear regressions were conducted for ASD and TD groups examining T1 predictors (MSEL VIQ & NVIQ, PPVT, EOWPVT) of middle childhood GORT-5 reading rate, accuracy, fluency, and comprehension. None of the T1 variables predicted significant variance in any TD reading measure. However, in the ASD group, when controlling for other T1 variables, the PPVT was a significant predictor of reading rate (β=.882, p=.048), reading accuracy (β=1.093, p=.011), reading fluency (β=1.043, p=.018), and reading comprehension (β=1.018, p=.008). This was the only significant preschool predictor of reading achievement in the sample.

Conclusions: The current study provides evidence that**,** consistent with previous research, basic reading skills are a relative strength for children with ASD, but reading comprehension is a relative weakness and the patterns of association between basic and higher order skills are weaker in ASD than TD. Furthermore, while the preschool cognitive and language variables in this study did not explain significant variance in the TD reading scores, preschool receptive vocabulary was a significant predictor of all reading variables in the ASD sample. This indicates a tighter association between early receptive oral language skills and later reading (receptive written language) skills in ASD than TD samples and has implications for the role both language and reading interventions may play in the development and education of children with ASD.

114 **206.114** Probing Symptoms of Autism in a Thin Slice

A. Riiff[1], *A. de Marchena*[2], *A. Muñoz Lavanderos*[3], *Z. M. Dravis*[1], *E. F. Ferguson*[4], *J. Beriont*[5], *V. Petrulla*[1], *A. Pomykacz*[6], *J. Parish-Morris*[7], *J. Pandey*[1], *R. T. Schultz*[1] *and* ***E. S. Kim***[1], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of the Sciences, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)The Center for Autism Research/CHOP, Philadelphia, PA, (5)Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, (6)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (7)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Interest in big phenotypic data, motivates development of behavioral probes for use in community settings outside the research lab. While the Autism Diagnostic Observation Schedule (ADOS; Lord et al, 2000) is a touchstone for measuring autism's core symptoms, its required intensive training and lengthy administration duration make it hard to deploy broadly in community settings.
Objectives: Inspired by appraisal from brief, "thin slices" of interaction (Grossman, 2015), and by rapid scoring of subtle pragmatic behaviors using semi-structured probes (Simmons, Paul and Volkmar, 2014), we constructed a 5-minute series of semi-structured probes and gestalt ratings, to score social communication behaviors known to differ in autism. Here we describe their performance.

Methods: Verbally fluent, high-functioning participants comprised a group of autistic children (n=14) and an age-matched group of typically developing controls (TDC; n=20). Ages ranged from 6 to 13 years (*M*=8.7 (*SD*=1.7)), for each group, respectively. Diagnostic status was confirmed by expert clinicians using comprehensive evaluation including ADOS. Verbal and full-scale IQ differed slightly between groups (FSIQ: ASD, 103.4 (12.3); TDC, 108.8 (16.3); d=0.37).

Probes were delivered by trained research assistants. They targeted (1) gaze-following joint attention; (2) informativity of speech and gestures, when narrating a story shown in a previously viewed cartoon video; (3) help-seeking communication, after being tasked with writing using a

secretly broken pen; and (4) integration of gesture with speech, when describing a previously-manipulated toddler's shape-sorting toy.

Probes comprised series of increasingly supportive prompts, providing opportunities to demonstrate varying levels of abilities, and facilitating rapid and reliable scoring of participant responses, from video, afterward. Scores matched probe hierarchies, and also included three gestalt ratings for awkwardness, quality of rapport, and quality of responses. Scores took integer values from 0, to 2, 3, or 4. Higher scores indicated lower performance (e.g., more prompting required or greater awkwardness).

Results: The ASD group scored a higher sum of probe scores (possible range = [0, 36], ASD: *M*=11.7 (*SD* = 10.0), TDC: 6.7 (3.7), *d*=0.66, *p*<.001), indicating worse performance. Speech-gesture integration differed between groups (*r*=.50, see Fig 1). In the ASD group, speech-gesture integration varied negatively with verbal IQ (*r*=-.61). There were marginal (*p*<.1) group differences in overall rapport (*r*=.35), amount of information in narration (*r*=.30), and prompt level required before requesting help (*r*=.42).

Response to subtler joint attention bids was associated with lower ADOS Social Affect (SA; *r*=.46, *p*<.05) and total scores (*r*=.39). Overall quality of responses increased marginally with age (*r*=-.31). Amount of information provided in narration was related to full-scale (FS; *r*=-.44), nonverbal (*r*=-.45), and marginally to verbal IQ (*r*=-.35).

Within the ASD group, response to subtler joint attention prompts likewise correlated with ADOS SA (*r*=.59) and marginally with ADOS total scores (*r*=.50). Awkwardness was marginally related to FSIQ (*r*=.59).

Conclusions: Group differences and relationships to autism symptom severity suggest the promise of using combined gestalt impressions and structured probes to measure a variety of core behaviors from a brief interaction.

115 **206.115** Prosody in Adolescents with Autism: The Impact of Language, Speech Motor Control, and Auditory Processing

M. V. Andrianopoulos *and C. E. Gargan, Department of Communication Disorders, University of Massachusetts, Amherst, MA*

Background: Some individuals with Autism Spectrum Disorder (ASD) exhibit differences in expressive and receptive prosody. There is lack of agreement regarding the characteristics and underlying processes associated with atypical prosody in this population. Current theories to explain atypical prosody in ASD range from poor language ability to speech motor control and/or auditory processing differences.
Objectives: We investigated the following research questions: 1) Do individuals with ASD perform less accurately than controls on expressive/receptive prosody tasks?; 2) Do individuals with ASD show significant differences on speech motor control tasks as compared to controls?; 3) Do individuals with ASD perform significantly different on auditory processing tasks compared to controls?

Methods: A between-group study was conducted to investigate prosody, language, speech motor control, and auditory processing among teenagers with ASD (n=11; ages 13;11 to 19;11 years) compared to TD controls (n=11) matched for age, gender, and receptive language (English). Participants completed: 1) standardized expressive and receptive vocabulary testing; 2) Profiling Elements of Prosody in Speech-Communication 2015 (PEPS-C 2015) to assess expressive/receptive prosody in pragmatic, affective, and grammatical domains; 3) Alternate Motion Rates (AMRs) to measure speed and precision of articulation, 4) Sequential Motor Rates to assess sequencing and coordination of the speech mechanism for articulation; and 5) the SCAN-3:A to screen auditory processing abilities. Trained listeners blind to participant group membership rated expressive prosody and motor speech tasks. Inter-rater reliability was good/moderate (Cohen's kappa >.55; Altman, 1991).

Results: There were no significant differences between groups on standardized expressive (*p*=.189) or receptive (*p*=.054) vocabulary. The group with ASD performed significantly less accurate (*p*<.05) than the TD group on 12 out of 14 PEPS-C 2015 tasks. Regarding speech motor control, the participants with ASD performed with significantly a lower (*p*<.05) group mean (slower speech rate) for repetition of [p^] and [k^] syllables. No significant differences between groups were observed on motor programming/planning (SMRs). Trained listeners rated participants with ASD as sounding qualitatively different or "atypical" than controls on motor speech tasks. No significant differences were observed in auditory processing abilities (p=.635). Qualitative analyses revealed that among the group with ASD, 82% "failed" the PEPS-C 2015 expressive/receptive composite scores. Among these individuals, 27% had *moderately to extremely low* language; 73% qualitative differences in motor programming/planning and motor execution (e.g., 25% sequencing errors; 50% imprecise or slurred speech, respectively); and 22% failed the SCAN-3:A. Two (18%) with ASD who "passed" the PEPS-C, had *moderately to extremely high* language abilities; 9% failed the SCAN-3:A; and 9% exhibited minor sound substitutions and variable speech rate. All TD participants passed the PEPS-C 2015, had *average* to *extremely high* language, no qualitative differences on motor speech tasks; and 18% failed the SCAN-3:A.

Conclusions: This research supports that some individuals with ASD have atypical prosody. The underlying mechanisms of atypical prosody in this population cannot be attributed to only one mechanism since motor speech, language and auditory processing abilities are intertwined. There is evidence to support poorer motor speech abilities compared to language performance and vice versa in some individuals with ASD.

116 **206.116** Quantitative and Qualitative Features of Co-Speech Gesture in Verbally Fluent Individuals with ASD

J. Leung[1], Z. M. Dravis[2], A. Bagdasarov[3], A. Muñoz Lavanderos[4], B. Mahoney[1], L. Adeoye[5], A. Riiff[2], A. Pomykacz[6], K. Bassanello[2], A. Faggen[2], S. Plate[2], M. Cola[2], V. Petrulla[2], L. Bateman[7], J. Pandey[2], J. Parish-Morris[2], C. J. Zampella[8], E. S. Kim[2], R. T. Schultz[2] and ***A. de Marchena****[1], (1)University of the Sciences, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)University of Pennsylvania, Philadelphia, PA, (5)The Center for Autism Research/CHOP, Phladelphia, PA, (6)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (7)The Center for Autism Research/CHOP, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:
Co-speech hand gestures augment verbal communication by mapping a visual accompaniment. Research on gesture in verbally fluent individuals with ASD is equivocal when it comes to how *often* gesture is used to supplement speech, suggesting that global variables (e.g., rate) may not adequately capture gesture differences in ASD. Thus, here we take a more granular look by investigating the communicative contribution of each individual gesture spontaneously produced during an interaction. The contribution of an individual gesture can be analyzed in at least two ways: quantitatively and qualitatively. A quantitative measure looks at how much *content* a gesture contributes to the interaction, whereas qualitative features measure how *well* a gesture carries out its intended purpose. We predicted that quantitative features would not adequately account for group differences in gesture use, given the countless nuances involved in live social interaction. Instead, we hypothesized that *qualitative*, or "subjective," features of gesture are more pronounced markers of ASD than *quantitative* features.

Objectives:

To test the hypothesis that qualitative features of gesture are more pronounced markers of ASD than quantitative features.

Methods:

Verbally fluent individuals with ASD (*n*=36), aged 10 to 35, and typically developing controls (TDC; *n*=14), were given two communication tasks to elicit co-speech gestures. Participants were group-matched on age, gender, and full-scale IQ. In the "Box" task, participants were asked to play with a shape-sorter toy for 15-30 seconds, and then asked to describe how it worked. In the "Cartoon" task, participants were shown a short clip of a cartoon, and then asked to describe it. Spontaneous gestures produced during both tasks were coded from videos for quantitative and qualitative features. Quantitative features included how often a gesture added *new information* to speech, and how often *two-handed* gestures were used—in other words, how often a gesture was cognitively or visually expansive. Qualitative features included *certainty* (rater's certainty that a given hand movement was a gesture), and *confidence* (rater's confidence in the intended meaning of the gesture). Coders were undergraduate student research assistants, who were naïve to participant diagnostic status. All variables were z-score transformed for comparison.

Results:

A mixed ANOVA yielded a significant Group*Measure (i.e., quantitative v. qualitative) interaction with a large effect size (p=.001, η^2=.21), see Figure. Post-hoc t-tests revealed that both qualitative features reached significance independently (certainty: p=.01, d=-0.78; confidence: p=.004, d=-0.86), with the ASD group showing lower qualitative ratings in both cases. In contrast, neither quantitative feature differed by group (*new information*: p=.11, d=.50; *two-handed gestures*: p=.32, d=.29), suggesting that gesturers in both groups made similar attempts to use their gestures to add content to the discourse.

Conclusions:

Qualitative features of gesture, such as certainty and confidence, may be more robust markers of ASD than *quantitative* features. That is, while the general content conveyed by individuals with ASD through gesture may be similar, their gestures may be less clear and thus less communicatively effective. Qualitative ratings are likely better predictors of group membership because they capture more of the nuances involved in nonverbal communication.

117 **206.117** Reported Use of Augmentative/Alternative Communication By Pediatric Psychiatric Inpatients with Autism Spectrum Disorders

D. L. Williams[1], *M. Siegel*[2] *and C. A. Mazefsky*[3], *(1)Communication Sciences and Disorders, Pennsylvania State University, University Park, PA, (2)Maine Medical Center - Tufts School of Medicine, Westbrook, ME, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: In previous work, we found that, contrary to expectations, verbal ability was not strongly related to the severity of problem behaviors in pediatric psychiatric inpatients with autism spectrum disorders (ASD) (Williams, Siegel, & Mazefsky, 2017). The potential effect of augmentative/alternative communication (AAC) use by the individuals with ASD who were minimally verbal (MV) remained an unanswered question. Other research has suggested that introducing a form of AAC such as Picture Exchange Communication System (PECS; Frost & Bondy 2002) or a speech-generating device may be associated with a decrease in the occurrence of problem behaviors for MV children with ASD (Ganz et al. 2009; Mirenda 2003).

Objectives: This is an initial descriptive report of AAC use in our population of pediatric psychiatric inpatients with ASD, adding to the limited information available on the proportion of youth with ASD who use AAC, the forms used, and the user characteristics.

Methods: A questionnaire, adapted from one by Tager-Flusberg and colleagues, was used to gather information from family members about AAC use, the verbal abilities, and communicative functions of 641 pediatric psychiatric inpatients with ASD. Receptive vocabulary was measured with the *Peabody Picture Vocabulary Test*-4 (Dunn & Dunn, 2007) for a subset of 479 inpatients.

Results: 242 (37.8%) of the pediatric inpatients reportedly used some form of AAC. They did not differ from the 399 inpatients who were non-AAC users in mean age [12.90 (users); 12.83 (non-users), p = .807], age range (4 to 20 years), or gender distribution [AAC users = 202 Males (83.5%); 40 Females (16.5%); non-users = 315 Males (78.9%); 84 Females (21.1%), p = 0.180]. The types of AAC that were reported to be used by most of the inpatients were low-tech, picture-based formats, with only 45.5% reported to use some form of a voice output communication aid or speech-generating device. Thirty-three percent of the AAC users were reported to use complex sentences; 49.5% were reported to share thoughts at least sometimes, but most (93.4%) used their means of communication for basic functions of expressing wants/needs and making requests. The receptive vocabulary scores of the non-AAC users were significantly higher than the AAC users (83.07; 47.09, p > .0001). A subset of 28 children in the non-AAC group were reported to only use simple sentences some of the time (85.7%) or never (14.3%) and had PPVT standard scores that ranged from 20 to 100 with a mean of 52.86, suggesting that, whereas some of these children may be so severely affected they would have difficulty using AAC, others may be potential candidates.

Conclusions: The percentage who use AAC in this inpatient population is consistent with previously reported estimates of AAC use in other ASD samples (Wodka et al., 2013). Consistent with other reports, this inpatient population primarily used AAC for the basic communicative functions of expressing wants/needs and requesting (Ganz et al., 2012). Future research will use information from the AAC questionnaire to examine the relationship between the ability to communicate and severity of problem behaviors in this population.

118 **206.118** Speaking the Same Language? a Comparison of the Language and Communication Profiles of Girls and Boys with High Functioning Autism

A. Sturrock[1] *and C. Adams*[2], *(1)Human Communication, Hearing and Development, The University of Manchester, Manchester, United Kingdom, (2)Human Communication Hearing and Development, The University of Manchester, Manchester, United Kingdom*

Background: Young females with Autism Spectrum Disorder (FwASD) present with more subtle impairments in social interaction (Lai et al 2011) and restricted interests (Mandy et al 2012) than male peers (MwASD). This may impact negatively on correct diagnosis of ASD in females (Kopp and Gillberg, 2011) which in turn reduces access to suitable services. Less is known about gender differences in communication for young people with ASD, especially high-level language/discourse. There is some evidence that gender differences are found in both functional communication (Park

et al 2012) and social impact of communication deficits (Sedgewick et al, 2016). Detailed investigation into subtle gender differences in language/discourse skills could support understanding of the female phenotype of autism and indicate areas of particular interest for this group; causal factors of poor well-being, appropriate diagnosis and bespoke therapy provision.

Objectives: To provide a thorough analysis of language and discourse skills for FwASD. To investigate all language domains: receptive/expressive skills, at word/sentence and above sentence level, and across pragmatic/semantic and language of emotion ability. To create a profile of skills for FwASD and compare skills sets with MwASD and typically developing females (FwTD) and males (MwTD).

Methods: Measures of structural language and functional communication were compared between 13 female and 13 male children (aged 8.11-11.06) with High-Functioning Autism Spectrum Disorder (HFASD); performance IQ normal range. 26 typically developing children (TD) were matched for age and gender. Subtle differences in PIQ were controlled during analysis. Participants were recruited through autism charities, NHS trusts and participant data bases. Assessments included: Standardised and experimental measures of vocabulary, sentence level and discourse level processing; Experimental pragmatic/semantic measures of non-linguistic communication, non-literal interpretation of spoken language and complexity of narratives; Novel experimental tasks of receptive and expressive emotion vocabulary. All assessments were conducted by clinical specialists, in school or at home. Analysis was undertaken using a 2 (Gender) x 2 (Group) analysis of variance (ANOVA), controlled for PIQ.

Results: Overall trends indicate that females with HFASD will outperform males with HFASD on a range of pragmatic and semantic tasks. However, they perform worse on these measures than TD females. TDs had consistently better scores than HFASD in above sentence level tasks (although not in measures of vocabulary or sentence level grammar where all groups showed matched results). Female HFASD perform similarly to TD females on some language of emotion measures (receptive and semantic category naming) and better than male TD or HFASD. These may represent relatively spared skills compared to gender norms.

Conclusions: Outcomes indicate a specific profile of language and communication strengths/weaknesses for female HFASD. They support the theory of a distinct female phenotype of ASD already identified in social skills and repetitive behaviours. They may indicate why FwASD fail to meet criteria for current diagnostic schedules, but also why they struggle to match communicative expectations of their female TD peer group. Results from this study have clinical implications for diagnostic services and speech and language intervention. As well as explaining difficulties maintaining friendships and managing well-being.

119 **206.119** Speech Impairment Affects Expressive Language in Minimally Verbal Children with Autism Spectrum Disorder

K. V. Chenausky[1], *A. Brignell*[2], *A. T. Morgan*[2] *and H. Tager-Flusberg*[3], *(1)Sargent College, Boston University, Boston, MA, (2)Murdoch Children's Research Institute and University of Melbourne, Melbourne, Australia, (3)Psychological and Brain Sciences, Boston University, Boston, MA*

Background:

25-30% of children with autism spectrum disorder (ASD) remain minimally verbal (MV) past age five (Kasari et al. 2013; Norrelgen et al. 2015). It remains unclear why spoken language acquisition is limited in these children, but we do know that a lack of spoken language is associated with high rates of challenging behaviors (Dominick et al., 2007) and is thus an important therapeutic target.

Speech impairment as a contributor to expressive language has been under-investigated relative to factors such as joint attention, language impairment, nonverbal IQ, and ASD severity, though disorders such as childhood apraxia of speech (CAS; a disorder in the planning and sequencing of speech movement; Iuzzini-Seigel et al., 2015) are hypothesized to be over-represented in ASD compared to the general population (Tierney et al., 2015).

Objectives: To estimate the proportion of individuals with MV ASD with speech impairment and to explore the contribution of measures of speech, receptive vocabulary, and nonverbal IQ to variability in expressive language.

Methods:

Videos of 57 individuals with MV ASD (13 F; ages 4;4-18;10) participating in the Kaufman Speech Praxis Test (KSPT; Kaufman, 1995) were coded for features of CAS and other speech anomalies. A consensus reliability method was used for coding.

One-way ANOVAs were performed to determine whether groups differed on age, ADOS severity, NVIQ, receptive vocabulary (PPVT), KSPT Section 1 (KSPT1; nonspeech oral-motor), and KSPT Section 2 (KSPT2; speech). Variables differing significantly between groups were entered into a hierarchical multiple regression to understand their contributions to the variance in Number of Different Words (NDW) from a structured language sample.

Results: Four groups emerged: No Abnormalities Detected, Non-CAS Speech Disorder, Suspected CAS, and Insufficient Speech to Rate. Groups differed significantly on PPVT, NVIQ, KSPT1, and KSPT2 (Table 1). The overall regression model including these four variables was significant ($F(4,40) = 8.672$, $p < 0.0005$), accounting for 41.1% of the variance in NDW (adj. R^2). However, KSPT1 and NVIQ contributed insignificant amounts of R^2. A reduced model including just KSPT2 and PPVT was also significant ($F(2,42) = 17.777$, $p < 0.0005$) and accounted for 43.3% of the variance in NDW (adj. R^2). PPVT score contributed a ΔR^2 of 0.126 ($p = 0.003$); KSPT2 contributed a ΔR^2 of 0.333 ($p < 0.0005$). PPVT and KSPT2 were not collinear (VIF = 2.8).

Conclusions: Minimally verbal individuals with ASD differ in the nature and severity of their speech involvement, suggesting the existence of separate speech endophenotypes in this population. Speech motor ability (KSPT2 score) accounted for significant variance in expressive language, with PPVT score accounting for additional significant variance. Speech impairment may limit expressive language development in some individuals with MV ASD and is an important area to explore for the creation of novel therapies for these children.

120 **206.120** Speech and Song Imitation in Autism Spectrum Disorder: A Cross-Linguistic Study

C. Dawson[1], *P. Q. Pfordresher*[2], *P. Wong*[3], *C. Jiang*[4] *and F. Liu*[1], *(1)School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Department of Psychology, University at Buffalo, SUNY, Buffalo, NY, (3)The Chinese University of Hong Kong, Ma Liu Shui, Hong Kong, (4)Music College, Shanghai Normal University, Shanghai, China*

Background:

Autism Spectrum Disorder (ASD) is characterized by difficulty with social communication, including understanding pitch in spoken language

(O'Connor, 2012), despite average or above average musical pitch processing skills (Bonnel et al., 2003; Heaton, 2003, 2005). Impaired linguistic but enhanced musical pitch processing has also been found in tone language speakers with ASD, such as Mandarin (Jiang et al., 2015). It remains unclear whether pitch production would also differ between music and language in ASD.

Objectives:

This study investigates pitch and duration matching in speech and song imitation of individuals with ASD and typically developing (TD) controls, who are native speakers of a language with or without lexical tone: Cantonese and English. This shows the effect of linguistic pitch expertise on pitch production in ASD and highlights differences in pitch processing between domains of speech and song among ASD individuals.

Methods:

Preliminary data were collected from 20 English speakers (11 ASD and 9 TD) and 10 Cantonese speakers (7 ASD and 3 TD). Participants listened to and imitated 48 (English) or 40 (Cantonese) sung and spoken sentences. Imitation recordings were analysed in Praat to extract median pitch and duration of each syllable rhyme and compared to model production. Absolute pitch and duration deviations were averaged across all syllables to obtain imitation accuracy for each sentence (Liu et al., 2013).

Results:

Linear mixed effects models were fitted for pitch and duration deviation separately for English and Cantonese speakers, with diagnostic group (ASD vs. TD) and domain (speech vs. song) as fixed effects and participants and stimuli as random effects.

For English, there was a significant main effect of domain on pitch and duration deviation, as both ASD and TD groups imitated song pitch better than speech pitch but speech duration better than song duration. A significant group x domain interaction was found for pitch deviation, as the TD group imitated speech pitch (but not song pitch) more accurately than the ASD group.

For Cantonese, there was a significant main effect of domain and a significant group x domain interaction on pitch and duration deviation. Song pitch was imitated more accurately than spoken pitch, and this advantage was enhanced among TD as opposed to ASD participants. Speech duration was imitated more accurately than song duration, and this advantage was enhanced among ASD as opposed to TD participants.

Conclusions:

Overall, results show that both ASD and TD groups imitated song pitch more accurately than speech pitch, in both English and Cantonese, and all groups imitated speech duration more accurately than song duration. Consistent with previous studies on American English and Mandarin speakers (Liu et al., 2013; Mantell & Pfordresher, 2013), these findings are expected since pitch precision in music is required and duration accuracy in speech is crucial.

Interestingly, compared to TD controls, English speakers with ASD were less accurate in speech pitch imitation, but Cantonese speakers with ASD were less accurate in song pitch imitation. This suggests that the symptomology of ASD may be different for individuals with different language background.

121 **206.121** Stability and Change in Language Development from 4 to 11 Years in Verbal Children with Autism Spectrum Disorder: A Community-Based Study

A. Brignell[1]*, K. Williams*[2]*, S. Reilly*[3] *and A. T. Morgan*[1]*, (1)Murdoch Children's Research Institute and University of Melbourne, Melbourne, Australia, (2)University of Melbourne and Royal Children's Hospital, Melbourne, Australia, (3)Griffith University and Murdoch Children's Research Institute, Gold Coast, Australia*

Background: Language difficulties are a common feature of autism spectrum disorder (ASD) and are associated with adverse outcomes including literacy difficulties, challenging behaviour and aggression (Mawhood 2000; Baghdadli 2003; Hartley 2008). Yet we understand little about how language develops for children with ASD compared with other children, particularly beyond the preschool years.
Objectives: We compared language ability at ages 4, 5, 7 and 11 in four groups of children: ASD with language disorder (ASD+LD; n=17), ASD without language disorder (ASD-LD; n=30), developmental language disorder (DLD; n=107) and typical language (TD; n=872). We also investigated predictors of language outcome in ASD.

Methods: Participants were selected from a large, prospective community-based cohort study of child language. A comprehensive, standardised language assessment (The Clinical Evaluation of Language Fundamentals- Fourth Edition; CELF-4) was used to assess receptive and expressive language across four time points. Mean scores on the CELF-4 and slopes (rate of language growth) were estimated from 4 to 11 years using generalised estimating equations. We used linear regression to analyse predictors of language outcome at 11 years.

Results: There was individual variability in scores and rate of growth for children in all four groups. For expressive language, children in the ASD-LD group had estimated mean scores that were 1.09 units lower than the TD group indicating similar ability at 4 years. By contrast the ASD+LD and DLD groups both had substantially lower estimated mean scores than the TD group (33.45 and 31.84 units lower, respectively). The estimated mean difference in slopes was similar for the ASD-LD and TD groups (p=0.905) indicating comparable rate of growth in language from 4 to 11 years. There was, however, a significant difference between the DLD and ASD+LD groups compared to the TD group (p=0.001 and p=0.003, respectively) indicating mean standard scores increased more quickly for the DLD and ASD-LD groups relative to the TD group from 4 to 11 years. This increased rate of growth was particularly evident for the ASD+LD group (Figure 1). The overall findings for receptive language were comparable to those for expressive language although rate of growth for the ASD+LD group was less rapid (Figure 2). Language at 4 years was the only consistent predictor of language at 11 years in the ASD group (p=0.001 for both receptive and expressive language).

Conclusions: For language ability and rate of growth, children with ASD-LD had similar profiles to children with TD, and children with ASD+LD had similar profiles to those with DLD. While rate of growth followed a predictable pattern (based on norms) for the TD and ASD-LD groups, those with DLD and ASD+LD demonstrated some developmental 'catch up' between 4 and 11 years. Language at 4 years predicted language at 11 years for ASD. These data can assist parents to better understand their child's language prognosis and inform intervention and service planning. The findings also contribute to our understanding of critical time periods for growth and development in children with ASD and how this may be similar or different to other groups of children.

122 **206.122** Syntactical Profiles of Autism Spectrum Disorder: Evidence from Part of Speech Errors on Expressive and Receptive Standardized Speech Assessments

T. McFayden[1], *J. O'Connell*[2] *and A. Scarpa*[3], *(1)Psychology, Virginia Tech, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA*

Background: Many individuals with Autism Spectrum Disorder demonstrate language difficulties, even if fluent language has been achieved, such as difficulties with grammar, prosody, and semantics. Previous research is mixed as to whether part of speech errors (e.g., nouns, verbs, adjectives), or syntax knowledge, is a deficit within ASD more broadly or is only present when ASD co-occurs with language impairment. Syntax accuracy is of particular interest from a sex-differences perspective, in that females with ASD have been said to engage in "social camouflage," using speech and communication patterns to better blend in.

Objectives: The following research investigates part of speech errors on standardized assessments of expressive and receptive vocabulary to (a) investigate syntactical differences as a function of ASD, and (b) to investigate syntactical sex differences within ASD.

Methods: Participants (N = 166, 57 females) comprised children (ages 2-10; n = 82), adolescents (ages 11-17, n = 20), and adults (ages 18-85, n = 64) who participated in an ASD assessment; of these, 98 received an ASD diagnosis. Each participant completed an IQ assessment and standardized measures of receptive language (Peabody Picture Vocabulary Test-4th edition; PPVT-4) and expressive language (Expressive Vocabulary Test-2nd Edition, EVT-2). Variables of interest included standard scores on both measures and proportion of errors (number of incorrect items/number of items administered). Thus, there were six total speech error variables: errors for nouns, verbs, and adjectives for both expressive and receptive errors.

Results: Multivariate analyses indicated significant sex and ASD diagnosis interactions that qualified both main effects for overall PPVT and EVT standard scores. On the EVT, no sex difference emerged for those without ASD, whereas females outscored males for those with ASD, $F(1, 156) = 5.32$, $p = .02$. On the PPVT, TD males outperformed TD females, whereas ASD females outperformed ASD males, $F(1,156) = 7.39$, $p = .007$. The six part of speech error proportion variables were treated as a unit and analyzed together as a syntactical profile. Latent profile analyses yielded a total of 3 profiles: high errors, low errors, and moderate errors. Logistic regression indicated that profile membership significantly predicted ASD diagnosis, $B = .413$, $p = .031$. Within the profiles, individuals with ASD were significantly more likely to reside in the profile with moderate errors, as opposed to excessive or few errors.

Conclusions: Results indicate significant sex and diagnostic differences on standardized measures of expressive and receptive language, with support for the social camouflaging hypothesis, such that females with ASD outperformed males on both indices and thus may use language and communication skills to better blend in. Furthermore, individuals on the spectrum do not seem to be making significantly more or fewer errors than their TD counterparts, but are more likely to make consistent, moderate errors on parts of speech both receptively and expressively. These results can aid in ASD assessment, in the assessment of the female ASD phenotype, and in the understanding and assessment of comorbidity of Specific Language Impairment within ASD.

123 **206.123** The Impact of Autistic Traits on the Affective Prosody and Gesture Perception in Conversation

L. Shim[1] *and F. E. Pollick*[2], *(1)School of Psychology, University of Glasgow, Glasgow, United Kingdom, (2)School of Psychology, University of Glasgow, Glagow, United Kingdom*

Background: Integration of speech and gesture is an essential ability that helps humans to participate in daily communication and social interactions. However, deficits in communication and social reciprocity are primary aspects of Autism-Spectrum Disorders (ASD) and several studies show that individuals with ASD have more difficulty in integrating audiovisual speech stimuli (Stevenson et al., 2014) and discriminating temporal asynchronies in linguistic situations (Bebko et al., 2006). The deficits in speech and gesture integration in ASD may reflect processes of multisensory integration that impact on social and emotional communication.

Objectives: This study is aimed to investigate the differences of emotional speech and gesture processing between individuals with low levels of autistic traits and high levels of autistic traits.

Methods: A total of 64 right-handed native English speakers between 18 and 40 years (25.20±6.11) participated in this study. The participants were divided into two groups: one group was a low autistic traits group (M:10, F:30) and one group was a high autistic traits group (M:8, F:16). We used a cutoff of below 18 to enter the Low AQ (LAQ) group and above 29 on the Autism-spectrum Quotient (Baron-Cohen at al., 2001) score to enter the High AQ (HAQ) group. Participants were presented with dyadic interactions and asked to respond about speakers' emotions from prosody (Task1&Task2: Audio-only), gesture (Task3: Visual-only), and with either emotionally congruent or incongruent displays (Task4: Audio-visual). For the audio-only and the video-only tasks, the stimuli included three emotional categories (Angry, Happy, Neutral). For the audio-visual task, stimuli included happy and angry emotions that were either congruent or incongruent across modality (Piwek et al., 2015).

Results: In the results of the prosody experiment, the HAQ group showed significantly lower accuracy than the LAQ group in Task2 ($F(1,186)=4.559$, $p=.034$). There was a significant emotion effect in both tasks (F-test, all $p<.001$). The HAQ group showed lower accuracy in recognising the happy emotion in both Task1 and 2. An interaction between group and emotion was found in Task2 ($F(2,186)=5.867$, $p=.003$).

In the gesture experiment, the HAQ group exhibited significantly lower accuracy than the LAQ group ($F(1,186)=11.272$, $p=.001$), and a significant main effect of emotion ($F(2,186)=260.001$, $p<.001$). Also, there was an interaction between group and emotion ($F(2,186)=12.135$, $p<.001$). In both groups, the angry gesture had the lowest percentage of correct recognition (LAQ: 42.9%, HAQ:40.1%).

In the congruence experiment, there was no group difference. A significant congruence effect was found ($F(1,124)=150.116$, $p<.001$) and a marginal group by congruence interaction ($F(2,124)=3.855$, $p=.052$). In reaction times, the HAQ group reacted slower than the LAQ group in all tasks, in particular a significant group difference was found in the congruence experiment ($t=-2.139$, $p=.036$).

Conclusions: This study investigated how autistic traits impact on affective prosody and gesture perception. The results of this study show that significant performance differences exist between low and high autistic trait individuals with the HAQ group presenting lower accuracy in recognising affective prosody and gestures. It suggests that consideration of these differences can contribute to understand the impact of autistic traits on social communication.

124 **206.124** The Language Delay in Preschool Children with Autism Spectrum Disorder with and without IQ Discrepancy

T. Y. Y. Yu[1], *H. P. Lin*[2], *J. C. Chow*[2], *W. Chou*[3,4] *and K. L. Chen*[5], *(1)Department of Occupational Therapy, College of Medicine, I-Shou University, Kaohsiung City, Taiwan, (2)Department of Pediatrics, Chi Mei Medical Center, Tainan, Taiwan, (3)Department of Rehabilitation, Chi Mei Medical*

Center, Tainan, Taiwan, (4)Recreation and Healthcare Management department, Chia-Nan University of Pharmacy and Science, Tainan, Taiwan, (5)Department of Occupational Therapy, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: IQ discrepancy (IQD) refers to the discrepancy between verbal and nonverbal intellectual abilities, indicating an atypical pattern of verbal-performance IQ differences (i.e., the distance between measured verbal [VIQ] and performance intelligence [PIQ] quotients). IQD appears to be related to several aspects of child development, but no studies have examined the association between IQD and language delay in children with autism spectrum disorders (ASD).

Objectives: The aims of the study were to establish whether 1) a group difference existed in the language delay among preschool-age children with ASD with different levels of IQD; 2) an association existed between IQD and language delay.

Methods: A total of 127 preschool children with ASD were divided into three groups according to the size of the IQD: EVEN IQ (n=90; IQD within 1 SD), discrepantly higher VIQ (n=14; VIQ > PIQ above 1SD [≥ 15 points]), and discrepantly higher PIQ (n=17; PIQ > VIQ above 1SD [≥ 15 points]). Children with ASD were assessed with the Language Disorder Scale of Preschoolers (LDS) and Wechsler Preschool and Primary Scale of Intelligence™ – Fourth Edition (WPPSI™-IV) respectively to measure their language disability and determine their IQD. The LDS contains three subtests: overall language ability, listening comprehension, and oral expression. Each subtest could differentiate three groups: normal, borderline, and delayed. Chi-square tests were used to examine the relationships between IQD and language delay.

Results: The results indicated significant differences among the three subgroups ($p < 0.05$) in the LDS. The results of the LDS show that 75 children had language delay in overall language ability (62.0%); 54 children in listening comprehension (44.6%); and 66 children in oral expression (54.6%). The FIQ, VIQ, PIQ, and IQD in the WPPSI-IV were 77.47 (SD = 35.65), 77.80 (SD = 14.89), 78.58 (SD = 16.27), and 10.49 (SD = 8.93) respectively, all of which were below the FIQ of 100 in the psychometric curve. Chi-square tests showed that IQD was related to children's overall language ability, listening comprehension, and oral expression ($X^2 = 17.30$, df = 4, $p = .002$; $X^2 = 19.59$, df = 4, $p = .001$; $X^2 = 15.30$, df = 4, $p = .004$). Children with even IQD showed better language ability than did children with discrepantly higher VIQ or PIQ. Moreover, children with discrepantly higher VIQ were associated with better language ability than were children with discrepantly higher PIQ, and vice versa.

Conclusions: The results of this study showed that IQD was significantly associated with language delay in children with ASD. The results of this study could encourage clinicians, educators, and therapists to consider IQD when measuring children's language function and to analyze the patterns of language disability in preschool children with ASD. Possible language problems of children with ASD may be detected early based on routine evaluation of cognitive profiles. Furthermore, the language delay could be explained in terms of IQD. Professionals should pay attention to children's language problems when they have IQD.

125 **206.125** The Relation between NON-Adaptive Behaviors, the Need for Transactional Support for Children with ASD and the Maternal Overburden

J. Perissinoto[1], *A. C. Tamanaha*[2] *and A. Armonia*[1], *(1)UNIFESP, São Paulo - SP, Brasil, Brazil, (2)UNIFESP, São Paulo, Brazil*

Background: Children with ASD have different needs of transactional support such as interpersonal as well as learning support in their day-to-day family lives and their school activities. These children may be relatively independent from the initiative and responsiveness of their adult partners; from the constant availability of the partners for each initiative, and how the partners can make adjustments in speech and in behavior to be of support for the day-to-day learning situations of the child.Along parallel lines, the degree of development shown by children with ASD can involve different things in the familial context, beginning with mental and physical strain as the result of the attributions of daily life, such as high levels of stress and low quality of life for the family members.

Objectives: To verify the possible relations between the need for interpersonal support and learning and maternal overburden.

Methods: The transversal study involved 56 individuals, which were split into two groups, one group of 28 children of both genders , with ages varying between 28 to 113 months; and a second group of 28 female individuals, ranging from 30 to 50 years of age. with diverse educational backgrounds, ranging from elementary graders to college graduates. These individuals are the respective mothers of the children with ASD, who themselves work at the Brazilian Public Health-Care Service. To register the interpersonal and learning support we used the SCERTS model for assessment (Prizant, Wetherby, Rubin, and Rydell, 2006). For non-adaptive behavior we used the Autism Behavior Checklist /ABC (Krug et.al.1993); pre-validated for Brazilian Portuguese as the Inventory of Autistic Behaviors/ IAB, (Inventário de Comportamentos Autisticos/ICA); and for the assessment of maternal overburden we used the Burden Scale (in the Brazilian translation of the Burden Interview, Scazufca,2002).

Results: According to the coefficient of Spearmen, the ABC indicated a correlation with the variables of response in the Burden and in the SCERTS for Interpersonal Support.

Conclusions: We observed that the greater the index of non-adaptive behavior, greater was the children´s with ASD need for interpersonal support and their maternal overburden.

126 **206.126** The Relationship between Verbal Fluency, Language and Executive Musical Working Memory in Children with Autism Spectrum Disorder

D. Macdonald[1], *G. Philibert-Lignieres*[1] *and E. M. Quintin*[2], *(1)McGill University, Montreal, QC, Canada, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Verbal fluency requires the ability to generate semantic responses to a target category. Studies have found both intact and impaired verbal fluency skills in children with autism spectrum disorder (ASD). Yet, deficits in executive functioning, social communication and often receptive and expressive language are well documented. Language skills may play a role in verbal fluency and executive functioning. However, the role of language proficiency in the relationship between verbal fluency and executive functioning in children with ASD is not well known. Language skills and executive functioning in children with typical development (TD) show improvement following musical training. Given musical strengths of children with ASD, we study the relationship between verbal fluency and executive function as used when playing music, i.e., executive musical working memory.

Objectives: To examine the relationship between verbal fluency and executive musical working memory of children with ASD with low and high levels of language skill.

Methods: Children with ASD (*N*=30) ages 8 to 12 years old participated in the study. They completed the Verbal Comprehension Index (VCI) of the Weschler Intelligence Scale for Children (WISC-V), and were divided into low (VCI <75, *n*=16) or high VCI groups (VCI > 75, *n*=14). Within each group, we examined the relationship between verbal fluency, as measured on the Delis-Kaplan Executive Function System (DKEFS) Category Fluency condition, and executive functioning, as measured by performance on an executive musical working memory task, measured as the total of their combined performance when judging whether 2 consecutive sequences of musical pitches were the same or different (calculated as Hits minus False Alarms ratio).

Results: DKEFS Category Fluency raw scores in the ASD group with lower VCI were significantly related to performance on the executive musical working memory task $F(2,13)=6.032$, $p=.014$, when accounting for age, with higher scores on one task associated with higher scores on the other task. In contrast, DFEKS Category Fluency in the ASD group with higher VCI was not significantly related to performance on the executive musical working memory task $F(2,11)=.881$, $p=.442$. We repeated analyses dividing groups with a cut-off VCI at 70 instead of 75 and found the same pattern of results.

Conclusions: These results suggest that language levels (VCI) influence the relationship between verbal fluency and executive functioning (executive musical working memory) in children with ASD, such that this relationship is stronger for children with ASD with language impairments (lower VCI levels) than those without language impairments. Findings shed light on the debate over verbal fluency abilities in children with ASD, suggesting that VCI and executive functioning skills should be considered when assessing verbal fluency, given the observed variation according to language levels. Finally, these results have implications for treatment for language and social communication in children with ASD and language impairments. Children with ASD and lower levels of VCI, as opposed to higher levels of VCI, may benefit more from musical training, known to improve verbal skills and auditory working memory in children with TD, to enhance their verbal fluency and social communication abilities.

127 **206.127** The Role of Communication Factors in Bolstering Early Speech Production Growth for Young Children with Autism: A Moderation Model

J. Blume[1], *K. Wittke*[2], *L. R. Naigles*[3] *and A. Mastergeorge*[4], *(1)Department of Human Development and Family Studies, Texas Tech University, Lubbock, TX, (2)University of Connecticut, Storrs, CT, (3)Psychological Sciences, University of Connecticut, Storrs, CT, (4)Texas Tech University, Lubbock, TX*

Background: Many children with autism spectrum disorders (ASD) are nonverbal in toddlerhood and preschool years (Anderson et al., 2007), often presenting with delays in gesture production (Iverson & Wozniak, 2007) and joint attention (Wetherby et al., 2007). Previous longitudinal findings have suggested nonverbal IQ is a strong predictor of later language, whereas Fusaroli et al. (2018) demonstrated that expressive language is the stronger predictor when examined with nonverbal IQ. Previous research has also demonstrated that joint attention is a predictor of later language, but primarily with standardized assessments as outcomes (Pickard & Ingersoll, 2015; Yoder et al., 2015). This study provides a unique contribution by including both social communication and early language samples in a moderation model predicting vocabulary growth.
Objectives: This study aimed to identify the unique roles of social communication elements including emotion and eye gaze, communication, and gesture in moderating growth in spoken language production between toddlerhood and pre-school.

Methods: A subset of secondary data collected longitudinally through the Autism Phenome Project (APP,*N*=55, 42 males, mean age at initial visit=33.9 months, SD=5.5) was utilized. The APP intends to define clinically meaningful ASD subtypes based on behavioral and biological data, specifically evaluating children immediately following ASD diagnosis at age 24-40 months and follow-up evaluations three years later. A simple linear regression analysis was performed for TWT at the age of diagnosis to predict growth in total word types (TWT) three years later. Subsequently, we performed multiple linear regression models incorporating the interaction effects of TWT and Social Composite scale elements from the *Communication and Symbolic Behavior Scales, Developmental Profile* (CSBS-DP; Wetherby & Prizant, 2002) Behavior Sample Social Composite scores (see Table 1).

Results: TWT at toddlerhood positively predicted TWT at preschool age in a simple linear model. This association remained significant with the addition of Communication scale performance and its interaction with TWT in toddlerhood to the model, suggesting when controlling for performance on the Communication scale and its interaction, an increase in TWT at toddlerhood by one SD above the mean increased TWT in preschool age by 0.714 SDs. The significant interaction suggested a moderator effect impacting toddler vocabulary growth (see Table 2). This was consistent with a significant negative moderation of the linear association between TWT in toddlerhood and preschool age by the performance on the communication scores in toddlerhood. Similarly, Social Composite score in toddlerhood negatively moderated the linear association between TWT in toddlerhood and preschool age. Performance on the Gesture scale and the Emotion and Eye Gaze scale did not significantly moderate this association.

Conclusions: These findings distinguish communication factors including rate, behavior regulation, social interaction, and joint attention as interactional parameters that uniquely explain the strength of relationship between TWT in toddlerhood at preschool age. The positive association between TWT at time of diagnosis and three years later was stronger in children with lower Communication scale scores in toddlerhood. Studies targeting social communication skills should focus on these underlying elements *directly* since indirect, growth effects in other social communication areas may co-occur.

128 **206.128** The Role of Early Social Motivation in Explaining Variability in Useful Speech in Young Children with ASD

P. L. Su[1], *A. Estes*[2], *S. Rogers*[3], *Z. Warren*[4] *and P. Yoder*[5], *(1)Hearing and Speech Sciences, Vanderbilt University, Nashville, TN, (2)University of Washington, Seattle, WA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)Vanderbilt University Medical Center, Nashville, TN, (5)Department of Special Education, Vanderbilt University, Nashville, TN*

Background: Abundant research has confirmed that children with ASD show deficits in both expressive and receptive vocabulary early in their development. However, the mechanisms that contribute to early language learning difficulties remain poorly understood. Social motivation may lead to relatively more processing of input which leads to more receptive language, which in turn, provides the semantic basis for expressive language.
Objectives: We tested the extent to which receptive language level measured at the mid-point of a 12-month intervention mediated the pathway

from baseline, pre-intervention, social motivation to expressive language level at the end-point of the study.

Methods: Seventy children with ASD between 15 and 30 months from a larger longitudinal randomized study of intensive treatment for toddlers with ASD were included in the current study. Seventeen participants from the larger study were excluded due to missing data. The larger study evaluates the effects of intervention intensity and style on the developmental quotients of young children with ASD. Social motivation at study entry was measured by the Social Approach subtest raw score from the Pervasive Developmental Disorder Behavioral Inventory (Cohen & Sudhalter, 1999). Receptive language level was measured 6 months after study entry (mid-point) and expressive language was measured 1 year after study entry using age equivalency scores from the Mullen Scales of Early Learning (Mullen, 1995).

Results: The confidence interval for the indirect effect of initial social motivation on endpoint expressive age equivalency score through midpoint receptive language excluded zero, and therefore, is significant (unstandardized *ab* = 0.1058, 95% CI = [.0090, .1990]; see Table 1 and Figure 1). Style or intensity of treatment did not moderate the mediated effect of mid-point receptive language on the association between baseline social motivation and end-point expressive language (all *p*s > .05).

Conclusions: The findings support the hypothesis that mid-point receptive language partially explains the association between early social motivation and later useful speech. This is consistent with an input-processing deficit explanation of language deficits in children with ASD. Future work will assess whether this mediated association occurs because social motivation leads to communication that elicits more input or whether social motivation leads to more processing of existing input. Both could explain an association between social motivation and receptive language (i.e., the a path of the indirect association).

129 **206.129** The Role of Linguistic Input in Person-Reference of Preschoolers with ASD

M. Barokova[1] *and H. Tager-Flusberg*[2]*, (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Numerous studies have examined the effects of linguistic input on children with autism's expressive language (e.g.,Fusaroli et al.,2018). In the domain of person-reference, or how a speaker refers to themselves and their conversational partner: using pronouns (e.g., I, you) or nouns/names (e.g., kiddo, mom, John), one study showed that the parental input of toddlers at high risk for autism was characterized by a higher use of the child's name, especially in the context of attracting the child's attention, compared to the input of low-risk toddlers (He et al.,2018). Furthermore, studies have provided evidence for children with autism's avoidance of pronouns and preference for using their own name (e.g.,Shield et al.,2015). Nevertheless, no study has directly examined the effect of parental input on person-reference in autism.
Objectives: We aimed to examine the relation between preschoolers with autism and their parents' person-reference. We focused on amount of person-referential language and on preference for one form of reference, pronouns, over the other, nouns/names, both concurrently and across time.

Methods: We collected language samples from children with ASD (N=38; 7female) and their parents during free play at three time points: T1:*M*=27.13months, T2:*M*=39.63, and T3:*M*=51.68. The samples were transcribed following standard SALT transcription procedures, and measures of person-reference were extracted for both children and their parents: proportion of person-reference words out of total words to reflect amount of person-reference, and proportion of pronouns and of nouns/names out of total words, and proportion of pronouns used over total number of person-referential words (pronoun and nouns/names) to capture the trade-off between the two forms of referential language. At each time point, children's ASD diagnosis was confirmed with the ADOS, and their cognitive and language ability was assessed with the Mullen(**Table-1**).

Results: There were no significant correlations between children's person-referential language out of total number of words and that of their parents either concurrently or across time points. Children used more pronouns than nouns/names out of total words at Time 2 and 3, and the proportion of pronouns out of total person-referential words did not change over time (**Table-2**). Parents used significantly more pronouns at each time point as well, and their preference strengthened across time ($\chi^2(2)=7.913, p=.019$). There were no significant correlations between children's proportion of pronouns and that of their parents either concurrently or across time after controlling for children's language ability and correcting for multiple comparisons.

Conclusions: In contrast to past research showing general influence of linguistic input on expressive language in autism, we found no associations between parents' and children's person-reference either in amount or in preference for one form of reference over the other. Children used significantly more pronouns and this preference did not change across time. These results combined with the children's relatively strong expressive language as evidenced by their Mullen scores suggest that the factors contributing to the use of person-reference in ASD may be primarily non-linguistic after a certain baseline language ability is achieved. These findings can inform clinical advice to parents about ways of addressing their children with ASD.

130 **206.130** The Social-Communicative Abilities in Young Children with Autism Spectrum Disorder: Profile and Prediction of Language

C. C. Wu*, Department of Psychology, Kaohsiung Medical University , Kaohsiung, Taiwan (Province of China)*

Background:
Previous studies have shown that early social-communicative abilities (i.e., joint attention, imitation) plays an important role for development of language ability in young children with autism spectrum disorder (ASD). Regarding early language ability is related to long-term outcomes and adaptive function in children with ASD. Thus, this study examines the profile of social-communicative abilities and predictors of language development in young children with ASD.

Objectives:

This study is planned to compare the abilities of joint attention and imitation in young children with ASD to young children with developmental delays (DD). In addition, we also examine the role of joint attention and imitation in language development among young children with ASD and with DD.

Methods:

There are 122 young children at 25 and 36 months of age, including 61 young children with ASD and 61 young children with DD. The Screening Tool for Autism in Two-Year-Olds, Taiwan version (T-STAT) was modified and used for measuring joint attention and imitation, including initiating joint

attention (IJA), responding joint attention (RJA), object imitation, and manual imitation. In addition, the Mullen Scales of Early Learning (MSEL) and Communication Subscale from Adaptive Behavior Assessment System -II (ABAS-II) were used to measure language abilities and communication adaptation respectively.

Results:

The results of this study showed that joint attention was core deficits in young children with ASD, especially for IJA. However, the imitation of young children with ASD was delayed instead of deficit. In addition, the profile of joint attention and imitation of young children with ASD and young children with DD could be separated. The poorest ability was IJA in young children with ASD while the poorest ability was the manual imitation in young children with DD. Both joint attention and imitation were significantly related to language ability in young children with ASD. However, only full-IJA and imitation were significantly related to language abilities in young children with DD. For young children with ASD, manual imitation was the strongest predictor of receptive language, expressive language, and communication adaptation. And, partial-IJA was the strongest predictor of expressive language. In addition, RJA was the strongest predictor of receptive language and communication adaptation. For young children with DD, only manual imitation was the strongest predictor of expressive language.

Conclusions:

This study revealed that IJA is robust challenge for young children with ASD again. This study showed that the profile of early social-communicative skills of young children with ASD and young children with DD could be different. In addition, the findings also supported that early social-communicative skills were related language in young children with ASD and with DD. However, early social-communicative skills contributed significantly development of language abilities in young children with ASD instead of young children with DD. The early social-communicative episodes provided interactive experiences and opportunities for young children with ASD and with DD to learning. Thus, it could enhance their language development through the mapping process. The results of the study provided implications for the early diagnosis and early intervention in young children with ASD.

131 **206.131** The Use of Formal Language As a Sign of ASD in Undiagnosed Children Attending Typical Schools

K. Francis[1], *H. Almahmeed*[2], *A. A. Al-Hashemi*[3], *M. Alhassan*[4] *and A. Terzi*[5], *(1)Almanara Child & Adolescent Psychiatric Unit, Kuwait Centre of Mental Health, Kuwait City, Kuwait, (2)Almanara Child & Adolescent Psychiatric Unit, Kuwait Centre of Mental Health, Kuwait Cty, Kuwait, (3)Almanara Child & Adolescent Psychiatric Unit, Kuwait Center of Mental Health, Kuwait City, Kuwait, (4)University of Reading, Reading, United Kingdom, (5)Department of Speech and Language Therapy, Technological Educational Institute of W. Greece, Patras, Greece*

Background: 'Diglossia' refers to the two varieties of the same language, which are used, under different conditions, by the same speakers within a community. In the 'diglossic' languages, we distinguish a common, colloquial or Low variety – L spoken in everyday situations and a more formal or High variety – H, reserved for specific contexts. The regular use of H as a medium of ordinary conversation is felt to be pedantic or artificial to the community. The Arabic language is a diglossic language with an L variety that varies significantly among the Arab countries, and an H-variety (Fushaa) common among all Arab speaking and commonly used in school books (but not in the teaching process by the teacher), in the Mosque, in most of the TV Arab cartoons and kids' series (e.g. sesame street was presented in Fusha), and in "serious" programs in TV.
Objectives: This study explores the clinical observation that children with ASD tend to use the "fushaa" more often than their neurotypical counterparts. We hypothesised that this feature could represent a reliable red flag for the identification of verbally fluent children with ASD that go undiagnosed.

Methods: In an observational cohort study design we screened through their teachers all the children with first language Arabic, fluent speaking children attending Arabic Kinder Garden in two of the 5 governorates of the state of Kuwait. The identified subjects were assessed for the use of the "fushaa" during audio-recorded structured tasks lasting 30 minutes. The corroborated cases were then further assessed for the extend of exposure to the "fushaa", their verbal IQ (PPVT-R), the presence of ASD (Social Communication Questionnaire and the ADOS-2), as well as for temperamental specific features (Children's Behavioral Checklist).

Results: Up to November 2018, we were able to screen 36 KGs from a total of 61, i.e. 3045 children out of 5000 (60.9%). Teachers identified 26 children as using "fushaa" in everyday life, 22 of whom where corroborated fushaa users (0,72%), and we got parent permission to assess 15 of them (68.2%). From these 11 children (73.3%) were classified as ASD cases.

Conclusions: The use of "fushaa" by young children in their everyday activities is uncommon. The high probability of these children to be classified as ASD establishes the use of this phenomenon as a significant red flag for ASD in children that they are very able and thus they have been missed. The results should be replicated in other diglossic environments to assess if the phenomenon is not limited to Arab speakers only, shedding light to the way able children with ASD acquire language.

132 **206.132** Understanding Pediatric Quality of Life in Autism Spectrum Disorder: Variability in Dimensions in Children with Varying Language Levels

A. M. Shui[1], *T. Katz*[2] *and V. Bal*[3], *(1)University of California San Francisco, San Francisco, CA, (2)Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO, (3)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

Background: Expressive language abilities vary widely in children with autism spectrum disorder (ASD); studies estimate that as many as 30% do not acquire spoken language. Compared to verbal children, minimally verbal (MV) children encounter different challenges that may affect quality of life. There is an urgent need for studies to explore whether existing pediatric quality of life scales are appropriate for use in children with ASD across language levels in order to promote investigations of quality of life that inform development of interventions appropriate for children of different ability levels.
Objectives: To compare the factor structure of the Pediatric Quality of Life Inventory (PedsQL) in MV children with ASD to children with phrase speech and children with fluent speech.

Methods: A sample of 2,380 children was drawn from the Autism-Speaks Autism Treatment Network (ATN) registry using the following criteria: at least 5 years-old at assessment, with ADOS and PedsQL data available. A confirmatory factor analysis did not support the five PedsQL subscales (RMSEA>0.07 or CFI<0.9) for any language group (defined using ADOS module: MV=Module 1, Phrases=Module 2, Verbally Fluent=Module 3 or 4). Thus, an exploratory factor analysis (EFA) was performed in each language group using Quartimin rotation on a polychoric correlation matrix.

Velicer's minimum average partial test was used to determine the number of factors in each solution. Absolute values of standardized regression coefficients ≥0.4 were considered in the factor loadings. In the case of split loadings, the factor with the highest absolute value loading was chosen.

Results: EFA yielded three factors for the MV and Phrases groups and four factors for the verbally fluent children. Internal consistency fell below the acceptable cut-off (alpha=0.7) for one factor in each of the MV and Phrases groups. Across all three language groups, a factor comprised of 5 of the 8 original physical items emerged. Results from MV and Phrases groups also yielded a factor comprised of items positively loading from the Emotion and negatively loading from the Social problems scales, suggesting a factor reflecting negative experiences. In contrast, negatively loading Emotion items and positively loading School items comprised a factor for verbally fluent children that may reflect positive experiences. Verbally fluent children also showed negative loadings of Physical and positive loadings of Social items, possibly reflecting an adaptive function factor.

Conclusions: The original PedsQL factor structure was not supported in the present sample of children with ASD. Furthermore, exploratory factor analyses provided evidence for different empirically-derived scales for children of varying language levels. Taken together, results suggest that the existing PedsQL scales may not be appropriate to assess quality of life in children with ASD and highlight a need for research considering dimensions of quality of life for children with ASD with varying ability levels. Further analyses will be conducted to explore how other factors (e.g., severity of restricted and repetitive behaviors), in addition to language, relate to quality of life on these empirically derived scales.

133 **206.133** Use of a Newly Developed Japanese Version of the Test of Pragmatic Language to Identify Children with Autism Spectrum Disorder from a Different Angle Than the Children's Communication Checklist-2

*R. Mizutani[1], **M. Oi**[2], S. Tanaka[3], Y. Yoshimura[4], C. Hasegawa[5] and M. Kikuchi[6], (1)United Graduate School of Child Development, Kanazawa University, Kanazawa, Japan, (2)Kanazawa University, United Graduate School of Child Dev., Kanazawa, Japan, (3)Rsearch Center for Child Mental Development, Kanazawa University, Kanazawa, Japan, (4)Research Center for Child Mental Development, Kanazawa University, kanazawa, Japan, (5)Kanazawa University, Kanazawa, Japan, (6)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan*

Background: Pragmatic impairment is a core characteristic of autism spectrum disorder (ASD). However, except for the Children's Communication Checklist-2 (CCC-2), few tests have been developed to evaluate pragmatic disability. As the CCC-2 is a parent report instrument, it cannot obtain data on language performance directly from children. To compensate for this limitation of the CCC-2, the Test of Pragmatic Language (TOPL) is administered to children. However, unfortunately, the TOPL cannot identify pragmatic language impairment better than the CCC-2. Therefore, in the present study, we developed a Japanese version of the TOPL (JTOPL) by devising 20 items regarding the comprehension of metaphors, irony, indirect requests, and control of politeness with another seven items regarding the status of the listener and selection of addressing form, among others.

Objectives: The purpose of the present study was to investigate whether the JTOPL reflects development when administered to elementary school children and discriminates between children with and without pragmatic impairment.

Methods: The JTOPL was administered to 102 typically developing (TD) elementary school children (48 boys, 54 girls; mean age: 117.58 months; standard deviation [SD]: 21.18). None showed Social Communication Questionnaire (SCQ) score over the cutoff point of 15. The mean number of correct responses to 27 items on the JTOPL was calculated for each of the six grades. The JTOPL was also administered to 11 elementary school children with ASD (10 boys, 1 girl; mean age: 116.45 months; SD: 19.74). The children with ASD were then compared with 54 randomly chosen TD children (48 boys, 6 girls; one per grade in terms of number of correct responses on the JTOPL). In addition, the correlation between the number of correct responses on the JTOPL and the general communicative competence (GCC) component of the CCC-2 was examined for TD children and children with ASD.

Results: The mean number of correct responses for each grade ranged from 21.6 to 24.8. These values did not differ in any pair of subsequent grades. The mean number of correct responses of the younger half of TD children was significantly lower than that of the older half ($p<.001$). The 11 children with ASD had significantly fewer correct responses than the 54 TD children ($p<.01$). No significant correlation was found between the number of correct responses on the JTOPL and the GCC component for TD children or children with ASD.

Conclusions: The results indicate that the JTOPL reflects development through elementary school age; however, a ceiling effect was seen in terms of the numbers of correct responses. To confirm the validity and reliability of the JTOPL, data from preschool children are needed. The JTOPL could discriminate between children with ASD and TD children while providing a different point of view from that of the CCC-2. While the CCC-2 focuses on inappropriate initiation, stereotyped language, use of context, and nonverbal communication, the JTOPL focuses mainly on figurative language comprehension reaching politeness control and the like. This difference might have led to the lack of correlation between the two instruments.

134 **206.134** Who Are the Bilinguals in the Autism Literature? a Systematic Review

***A. B. Choi**[1], R. Hantman[2] and G. Luk[3], (1)Harvard University, Cambridge, MA, (2)Harvard Graduate School of Education, Cambridge, MA, (3)McGill University, Montreal, QC, Canada*

Background:

Many children with autism spectrum disorder (ASD) are growing up in bilingual environments (Fahim & Nedwick, 2014), yet only limited research has explored how ASD and bilingualism intersect (e.g., Drysdale et al., 2015; Hambly & Fombonne, 2012). Evaluating and synthesizing the literature on the intersection of ASD and bilingualism is complicated by bilingualism's multifaceted operationalization (e.g., language proficiency, history, and contexts; Surrain & Luk, 2017) and ASD's heterogeneity (e.g., variability in language profiles; Tager-Flusberg, 2016).

Objectives:

We systematically review the labels, descriptions, and language framing bilingualism and ASD within the autism literature. By documenting the variability in describing language backgrounds and ASD characteristics, we hope to highlight the nuances embedded in understanding the interplay between the two variables. This objective is required to advance knowledge about ASD for children from diverse language backgrounds, as bilingualism is not necessarily a choice for some individuals with ASD.

Methods:

We searched six databases (ERIC, PsycINFO, Academic Search Premier, Education Abstracts, Linguistics and Language Behavior Abstracts, and Web

of Science) using keywords (*autis**or *ASD*or *asperger**or *pervasive develop**)AND (*biling** or *multiling**or *"language learner*"*or *"second language")*. This electronic search identified 319 articles (see Figure 1 for our identification process); 170 articles from a previous, pilot search were added, yielding 489 articles in total. After removing duplicates, 289 articles were identified and screened based on titles, abstracts, and keywords. Included studies met three inclusion criteria. First, studies were conducted with stakeholders in the field of autism (e.g., children with ASD, parents, service providers). Second, we included studies with participants who spoke more than one language. Reviews were included only if they discussed literature concerning both stakeholders in the field of autism and participants who were multilinguals. Third, papers were published in English and were peer-reviewed. Ninety-six papers fit these criteria and were included in the final database. For this abstract, we assessed twelve full-text articles and coded labels and descriptions used to characterize participants.

Results:

In this preliminary analysis, twelve studies (seven qualitative, four quantitative, and one review) included 199 participants. About half of the empirical studies were conducted in North America (55%). When describing the language backgrounds of bilingual participants, nine out of eleven studies described language proficiency; however, only two used subjective ratings and/or objective assessments to measure proficiency. Three studies used learning labels such as "English as a second language". Two papers used a language pair label (e.g., "English-Chinese bilingual"). No papers described the participants' language dominance (e.g., "nearly balanced bilingual"). When describing the participants with ASD, seven out of eleven studies (64%) did not use any assessments to diagnose or confirm ASD. Three empirical studies (27%) reported nonverbal/verbal functioning of the participants. No studies described the severity of ASD symptoms.

Conclusions:

The substantial variation in the descriptions of language and autism-specific characteristics across studies on bilingualism and ASD calls for more consistent and transparent reporting of participant characteristics. Clarity in reporting is critical to building our understanding of how bilingualism and ASD intersect in behavioral outcomes.

135 **206.135** Wugz, Wugs, or Wugzez? Morpheme Generalization in TD Children and Children with ASD

V. Tecoulesco *and L. R. Naigles, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Using the plural and past tense morphemes correctly with novel words (e.g., wugs, blicked) indicates that children have internalized these grammatical patterns of English (Berko, 1958). Typically developing (TD) children demonstrate this knowledge in preschool; however, children with Autism Spectrum Disorder (ASD) appear to show severe delays. In particular, researchers have reported that 4-year-olds with ASD produce plurals with novel nouns less than 25% of the time, and regular past tense with novel verbs less than 10% of the time (Park et al., 2012). The developmental origins of this delay are unclear; for example, whether it is rooted in lexical versus grammatical difficulties.
Objectives: The current study uses a longitudinal design to address two questions: (a) Do older children with ASD show better performance on the 'Wug' test? (b) How is their performance on this test predicted by their vocabulary and grammatical talk when they were preschoolers?

Methods: Fifty-eight children between the ages of five and seven years, 29 typically developing (TD) children (M= 5.57 years, SD=.33) and 19 children with ASD (M=6.47 years, SD=.51) participated in the Wug test. Two years previously, they had also been recorded during 30-minute naturalistic mother-child interactions, and their speech was transcribed and coded for noun, verb, plural, and past tense usage. At that time, they were matched on language ability. Currently the TD group outperforms the ASD group on the Test for Auditory Comprehension of Language (TACL) ($t(48)=29.274, p<.001$).
For the Wug test, the children were shown a picture and told, "This is a wug. Now there are two of them. There are two___." Or for verbs "This man knows how to mot. He is motting. He did it yesterday. Yesterday he ___". The current study used seven nonwords to elicit regular plural endings (e.g., wug, gutch, and nizz) and six to elicit regular past tense forms (e.g., mot, rick, and gling).

Results: During the Wug test, the TD group produced significantly more regular plural ($t(47)=2.55, p=.014$) and past tense forms ($t(47)=2.95, p=.005$) than the ASD group. Group means, shown in Figure 1, are markedly higher, though, than those reported by Park et al. (2012). Performance for both groups with plurals was positively correlated with their use of plurals (but not noun types or tokens) in spontaneous speech two years earlier (TD group: $r=.528, p=.036$; ASD group: $r=.503, p=.168$). In contrast, performance for both groups with past tense was positively correlated with their use of verbs (but not past tense morphemes) in spontaneous speech two years earlier (TD: $r=.486, p=.007$; ASD: $r=.584, p=.011$).

Conclusions: While the ASD group still lagged behind the TD group, their ability to generalize the plural and past tense morphemes to novel nouns and verbs was much higher than reported for preschoolers (Park et al., 2012), indicating that their grammatical development is continuing. Interestingly, while their knowledge of plurals seems linked to their earlier grammatical usage, their knowledge of past tense seems more closely linked to their earlier lexical usage, suggesting that noun and verb morphology may rely on different aspects of knowledge during acquisition.

136 **206.136** 'Autistic'-Sounding: A Latent Class Linear Mixed Modeling Approach to Parsing Heterogeneity in Children's Natural Conversations Using Acoustic Properties of Speech

J. Parish-Morris[1]*, S. Cho*[2]*, M. Liberman*[3]*, N. Ryant*[2]*, K. Bartley*[4]*, M. Cola*[1]*, S. Plate*[1]*, L. D. Yankowitz*[1]*, V. Petrulla*[1]*, A. Riiff*[1]*, C. J. Zampella*[4]*, J. D. Herrington*[5]*, E. Sariyanidi*[4]*, B. Tunc*[4]*, E. S. Kim*[1]*, A. de Marchena*[6]*, J. Pandey*[1] *and R. T. Schultz*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Linguistic Data Consortium, University of Pennsylvania, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, (6)University of the Sciences, Philadelphia, PA*

Background:
Behavioral heterogeneity is a persistent challenge for researchers and clinicians aiming to develop evidence-based social communication interventions for children with autism spectrum disorder (ASD), and to pinpoint the condition's biological bases. Even after attempting to manufacture homogeneity by restricting variables such as age and IQ within study samples, children with ASD still behave very differently across contexts (e.g., consider a standardized vocabulary test versus playground conversation). This study uses a latent growth curve approach to parse acoustic heterogeneity in the spontaneous speech of children with ASD.

Objectives:

Test whether patterns of 'ASD'-like utterances characterize subgroups of children with ASD over the course of a short, naturalistic conversation

with a friendly stranger.

Methods:

Language samples from 35 verbally fluent children with ASD were drawn from an unstructured 5-minute 'get-to-know-you' conversation with a novel confederate who was not an autism expert. All children had IQ estimates in the average range (>75), and were aged 7-16.9 years. Children produced a total of 2,408 useable utterances (mean=68.8 utterances each). Each utterance was classified as 'ASD' or 'TD' using a machine learning classifier with 5-fold cross-validation, developed on the acoustic properties of speech produced by a larger matched sample that included both diagnostic groups (sample described in Cho et al., this conference). The number of 'ASD'-like utterances produced over the course of the conversation (~1-minute windows) was tested for the presence of latent classes ('lcmm' in R). Class member characteristics were compared using simple linear models.

Results:

A 2-class model provided the best fit for the data (as compared to 3 or 4 classes) and revealed evidence of homogeneous subgroups with (1) Increasing (N=23) or (2) Steady (N=12) numbers of ASD-like speech utterances over the course of the conversation (Figure). Group intercepts differed significantly from one another, with the Increasing group producing more ASD-like utterances at the start of the conversation (coefficient: -2.08, Wald test=-2.40, p=.02). Members of the Increasing subgroup produced growing numbers of utterances classified as 'ASD' over time (Coefficient=.49, Wald test=5.97, p<.0001), while the relationship between time and ASD-like utterances trended negative in the Steady subgroup (Coefficient=-.18, Wald test=-1.65, p<.10. Class members did not differ on age, sex ratio, nonverbal IQ estimates, ADOS-2 calibrated severity scores, average turn length, or the number of utterances produced at the group level, but did differ on verbal IQ scores (Steady > Increasing; estimate=11.58, t=2.97, p=.003) and word count (Steady < Increasing; estimate=-150.58, t=-2.88, p=.007).

Conclusions:

Machine-learning classification of speech utterances renders it possible to parse heterogeneous samples into more homogeneous subgroups that dynamically change over the course of a conversation. In this exploratory study, we found two subgroups of children that sound more or less 'ASD-like' over time, with the more talkative group sounding increasingly atypical over 5 minutes. Future research using an expanded sample will include language-based analyses within each class (current results are based on acoustic properties only). This 'profiling' approach holds promise for identifying subgroups that benefit from specific interventions and stands to advance the goal of personalized medicine.

137 **206.137** Individuals with Higher Levels of Autistic Traits Show More Lexically-Guided Perceptual Learning

T. Karaminis[1], *P. Drozdova*[2] *and O. Scharenborg*[3], *(1)Department of Psychology, Edge Hill University, Ormskirk, United Kingdom, (2)Radboud University, Nijmegen, Netherlands, (3)TU Delft, Delft, Netherlands*

Background:

Speech is inherently variable as people pronounce words differently depending on, e.g., accent, dialect, gender or age. To cope with this variation, in our social interactions, we continuously tune into individual speakers. More specifically, we employ lexical and phonotactic knowledge to decode ambiguous speech sounds; and we adjust our phonetic categories (in broad terms: our expectations for how phonemes ought to sound) to include such ambiguous sounds. This phenomenon, referred to as lexically-guided perceptual learning is important for our ability to communicate effectively.

Lexically-guided perceptual learning is also relevant to a family of recent theories of autistic perception formulated within the Bayesian and the predictive-coding computational frameworks. These accounts propose that autistic individuals present fundamental limitations in calibrating their perceptual systems to current environments by using knowledge accrued from recent sensory experiences. Previous studies have examined such limitations focusing on non-linguistic domains. In this study, we examine whether such limitations are also present in speech perception. If so, we should predict that autistic individuals and individuals with higher levels of autistic traits present less pronounced lexically-guided perceptual learning effects compared to individuals with lower levels of autistic traits.

Objectives:

We sought to test this prediction by examining the relationship between lexically-guided perceptual learning and autism traits in adults.

Methods:

In an ongoing study, we tested 47 adults (22 females) aged between 18 and 64 (M = 26.07; SD = 10.80). Each participant was administered a lexically-guided perceptual learning paradigm from an existing study (Drozdova et al., 2015) and subsequently completed the Autism Quotient questionnaire.

The lexically-guided perceptual learning paradigm had an 'exposure-test' design. Participants were first exposed to a short story containing an ambiguous sound from the [l/r] continuum. Each participant heard one of two versions of the story (learning conditions), in which the ambiguous sound replaced either all [r] sounds or all [l] sounds. Next, participants completed a phonetic-categorization task on a continuum of ambiguous [l/r] sounds.

We analysed the responses in the phonetic-categorization task with mixed-effect statistical modelling, and used the number of responses that were consistent with the learning condition as the dependent variable, similar to the original study. Here, the fitted statistical model also included effects of autistic symptomatology.

Results:

Analyses showed that, on average, our participants presented reliable lexically-driven perceptual learning effects, which, similar to the original study, manifested in the first levels of the [l/r] continuum. Contrary to our prediction, individuals with higher levels of autistic traits presented more pronounced lexically-driven perceptual learning effects than individuals with lower levels of autistic traits.

Conclusions:

The patterns of individual variability in lexically-driven perceptual learning effects in our study are in the opposite direction to our prediction based on recent Bayesian and predictive-coding accounts of autistic perception. Our results challenge these accounts to accommodate individual differences in speech processing.

Our results are consistent with accounts suggesting enhanced perceptual abilities in autistic individuals or individuals with higher levels of

autism traits. Our current work involves explicitly examining differences between autistic and neurotypical individuals in lexically-driven perceptual learning.

Poster Session
207 - Diagnostic, Behavioral, Sensory and Intellectual Screening and Assessment
5:30 PM - 7:00 PM - Room: 710

138 **207.138** Speech Abnormalities Associated with ASD in Children with Vision Impairment

Z. Nir *and C. Shulman, The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background:
Vision impairment affects child development, including social communication development (Vann et al., 2015; Hobson, 2005). Research reveals an overlap between the profiles of social behaviors in children with vision impairment and those characteristic of children with ASD (Do et al, 2017(. In addition, speech abnormalities such as echolalia, repetitive and stereotype use of language and part of the "autistic- like" features that are common in children with vision impairment.

Objectives:

The main purpose of this research was to characterize developmental profiles of pre-school children with vision impairment. Another objective was to observe the prevalence of unique speech patterns and speech abnormalities in this group.

Methods:

Thirty-two pre-school children participated this research. They were three to six years old, and all had a diagnosis of significant visual impairment. All of the children were recognized by the ministry of Education as vision impaired and received educational aid by an expert in vision education. The level of vision impairment varied from moderate to blind.
All the children in this research had a compressive psychological evaluation. The evaluation included both developmental evaluation tools that are common at the general population and special designed tools for children with vision impairment. To assess general development level the Mullen Scales of Early Learning (MSEL) and the Reynell-Zinkin scales (RZS) were used. Adaptive behavior skills were measured by Vineland Adaptive Behavior Scales, third edition (Vineland-3) and communication and social skills were assed with the Childhood Autism Rating Scale (CARS2) and the Visual Impairment and Social Communication Schedule (VISS) (Absoud, Parr, Salt & Dale, 2011).

Results:

Children with vision impairment show a variety of Speech abnormalities such as echolalia, repetitive and stereotype use of language. Those abnormalities occurred in all levels of development in children with vision impairment.

Conclusions:

The fact that speech abnormalities are common in visually impaired children regardless of the developmental level or the severity of the visual impairment suggests that the use of repetitive language may be an adaptive behavior rather than an abnormal one. This findings require a further research**.**

139 **207.139** Measures of ASD Severity in Children with Autism and Other Developmental Delays Are Related to Sociodemographic Factors

S. Rosenberg[1]*, L. Wiggins*[2]*, B. Barger*[3]*, C. DiGuiseppi*[4]*, G. N. Soke*[2]*, R. Landa*[5]*, L. Schieve*[2]*, L. C. Lee*[6]*, E. Moody*[7]*, E. Rubenstein*[8]*, K. Kaparich*[9]*, L. Stewart*[10]*, A. McKenzie*[9]*, C. Colbert*[11]*, D. Magnusson*[12] *and C. Robinson Rosenberg*[13]*, (1)University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Centers for Disease Control and Prevention, Atlanta, GA, (3)Georgia State University, Atlanta, GA, (4)Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, CO, (5)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (6)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (7)University of Colorado, Denver, Aurora, CO, (8)Waisman Center at UW Madison, Madison, WI, (9)Department of Psychiatry, University of Colorado Denver, Aurora, CO, (10)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (11)Colorado School of Public Health, Aurora, CO, (12)Physical Therapy, University of Colorado School of Medicine, Aurora, CO, (13)University of Colorado / JFK Partners, Aurora, CO*

Background:
Previously we reported that family income, maternal education, and maternal race decreased the specificity of standardized parent-report autism spectrum disorder (ASD) screening instruments. Additional study is needed to examine how both maternal and clinician reports of ASD symptom severity are related to sociodemographic factors, as well as the correspondence between maternal and clinician reports of ASD symptom severity.

Objectives:

To examine associations between sociodemographic characteristics and scores on instruments that rated child ASD severity completed by mothers and study clinicians, as well as to assess the correspondence between ASD severity scores obtained from mothers and clinicians.

Methods:

We used data from the Study to Explore Early Development (SEED), a multi-site case-control study exploring the phenotypes and determinants of ASD. Participants for this analysis were aged 2-5 years in 2007-2016 and were recruited through educational and healthcare organizations providing services to children with ASD and other developmental delays (DD). Analyses were limited to children whose birth mothers were the reporters. Demographic data were collected in a standardized maternal phone interview. Perspectives on child ASD severity were collected from the mother via the Social Responsiveness Scale (SRS) and from the study clinician using the Ohio State University Autism Rating Scale (OARS). The OARS was completed after a direct observation of the child, as well as a review of all other information available on the child.

We used analysis of variance to examine the relationship between each measure of symptom severity and the sociodemographic factors. Both models, one for the SRS, another for the OARS, included the following independent variables: family income, maternal age, maternal education, maternal race, maternal ethnicity, language spoken in the home, and child sex. To assess the correspondence of maternal and clinician ASD

severity estimates, Pearson correlations were obtained for the OARS with the SRS. Tests for collinearity indicated this was not a concern for these models.

Results:

Lower education (F=6.04, p<.00), lower income (F=6.26, p<.00) and non-white race (F=7.84, p<.00) were associated with higher severity scores on the SRS. Lower education (F=7.62, p<.00), non-white race (F=11.04, p<.00), male sex (F=50.74, p<.00) and younger child age (F=7.53, p<.00) were associated with higher scores on the OARS. The OARS and SRS were strongly correlated (r=.71).

Conclusions:

These results indicate that non-white mothers and those with low education and income report elevated levels of ASD severity in their children with ASD or DD. The strong agreement between maternal and clinician reports of severity of child symptoms suggests the reports of symptom severity reflect true differences in child behaviors. Nevertheless cultural and educational impacts on maternal reporting on self-administered questionnaires cannot be entirely ruled out. Future research is needed to determine the impact of different maternal severity thresholds on access to services.

The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention.

140 **207.140** Measuring Improvements in Social Functioning Following Intervention in Young Children with Autism Using the Stanford Social Dimensions Scale

R. K. Schuck[1], *M. Uljarevic*[2], *G. W. Gengoux*[1], *E. Gagnon*[3], *M. Kaufman*[4], *A. Y. Hardan*[5] *and J. M. Phillips*[5], *(1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)PGSP-Stanford Psy.D. Consortium, Palo Alto, CA, (4)PGSP-Stanford Psy.D. Consortium, Palo Alto, CA, Palo Alto, CA, (5)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA*

Background: Impairments in social functioning are a hallmark of autism spectrum disorder (ASD). Many interventions target a range of different components necessary for social functioning. However, currently available measures provide limited sampling of discrete social dimensions, and their capacity to detect change during and after interventions is currently not well established. The Stanford Social Dimensions Scale (SSDS) is a tool currently under development aiming to provide assessment of constructs broadly related to social constructs of the Research Domain Criteria approach such as as understanding of mental states and others' emotional expressions, affiliations and social motivation, social communication, and unusual social approach. The measure has been specifically designed for use in clinical trials to detect changes in social functioning over time. Therefore the SSDS might be particularly well suited as an outcome measure following early autism interventions that target different aspects of social functioning such as Pivotal Response Treatment (PRT) and other naturalistic developmental interventions.
Objectives: The current investigation aimed to determine whether the SSDS is sensitive to change following interventions targeting social skills for young children with ASD. Results reported here are a preliminary part of ongoing treatment studies.

Methods: To date, twelve participants (8 male, 4 female) aged 27 - 84 months (mean: 54.92) participated in the study. Six participants were randomly assigned to receive early intervention focused specifically on enhancing social motivation and reciprocity; 6 were assigned to a wait-list control group and continued stable community-based treatments. Parents filled out the SSDS at baseline and at the end of the study. Repeated measures ANOVA were utilized to assess changes in SSDS scores from baseline to follow-up.

Results: At baseline, the SSDS exhibited excellent internal reliability (Cronbach's alpha = .93). The groups did not differ significantly in IQ at baseline ($t(6.988)=.032$, $p = .975$). and total SSDS scores were also consistent between participants in the treatment and control groups ($t(9.804)=-.240$, $p = .815$). For the participants who received treatment, SSDS scores in the domain of understanding of mental states and others' emotional expressions increased significantly from pre- to post-treatment ($F(1) = 7.893$, $p = .038$, $\eta^2 = .612$), suggesting improvement in measured ability to perceive and interpret social signals. No changes in this domain were observed in the control group ($F(1) = .241$, $p = .644$, $\eta^2 = .046$). There were no significant differences from baseline to follow-up in either group on the total SSDS score and in the other subdomains.

Conclusions: Following intervention targeting different social skills in young children with ASD, improvement was observed in their understanding of mental states and others' emotional expressions based on the Stanford Social Dimensions Scale. Findings reported here provide very preliminary evidence for the utility of the SSDS as a sensitive measure for measuring different aspects of social functioning following social intervention in young children with autism. Results from this investigation including additional data from ongoing work will be discussed.

141 **207.141** Mental Health and Cognitive Outcomes in High-Risk Infant Siblings Followed Longitudinally to Ealry Adolescence: Patterns and Predictors

A. Solish[1], *J. A. Brian*[1], *I. M. Smith*[2], *J. H. Leef*[3], *L. Senman*[4], *N. Garon*[5], *T. Vaillancourt*[6], *W. Roberts*[7], *P. Szatmari*[8], *C. Roncadin*[9], *L. Zwaigenbaum*[10] *and S. E. Bryson*[11], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)Department of Applied Psychology and Human Development, University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Autism, Bloorview Research Institute, Toronto, ON, Canada, (5)Mount Allison University, Sackville, NB, Canada, (6)University of Ottawa, Ottawa, ON, Canada, (7)isand, Toronto, ON, Canada, (8)The Hospital for Sick Children, Toronto, ON, Canada, (9)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (10)University of Alberta, Edmonton, AB, Canada, (11)Dalhousie University, Halifax, NS, Canada*

Background: Having followed a large high-risk (HR) cohort (siblings of children with ASD) from infancy, we examined early predictors of outcomes as they enter mid-to-late childhood/early adolescence. We focus on mental health and cognitive outcomes in relation to early temperament and attention.
Objectives: To examine mid/late childhood/adolescent mental health and cognitive outcomes, and predictors thereof, in a HR sibling sample.

Methods: We re-assessed 117 HR siblings (72 boys; 45 girls; *M* age = 9.6 years; range = 7.7-13.6), followed from age 6 or 12 months, to examine later mental health and cognitive outcomes. Based on blinded clinical best-estimate assessment, 41 met criteria for a diagnosis of ASD (76 = non-ASD). Variables analyzed included: (1) early temperament (Toddler Behavior Questionnaire; TBQ, at age 2) and cognition (Mullen Scales of Early Learning; ages 1 and 2), and (2) mid-to-late childhood/adolescent mental health (Child Behavior Checklist, Ages 6-18; CBCL) and cognition (WISC-V).

Results: ***(1) Mental Health Outcomes***: High-risk siblings with and without ASD experienced high rates of parent-reported symptoms on the CBCL, with > 10% of both Non-ASD and ASD sub-groups experiencing symptoms in the clinical range (*T*-scores > 90th %ile) in Internalizing (17.1%; 35.1%) and Externalizing (14.3%; 35.1%) areas, with groups differing only in rate of Externalizing symptoms (p = .007). Elevated rates of clinically concerning (i.e., borderline or clinical range) problems were reported for siblings with both non-ASD and ASD outcomes for Anxious/Depressed (12.9%, 27%), Withdrawn/Depressed (11.4%, 33.4%), Somatic Complaints (12.8%, 16.2%), and Aggressive Behaviour (14.3%, 33.2%). Elevated DSM-oriented scales included Affective (12.9%, 37.8%), Anxiety (14.2%, 37.8%), Somatic (11.6%, 13.5%), Oppositional (12.9%, 27%), and Obsessive-Compulsive (12.8%; 29.7%) scales. TBQ Attention Shifting at age 2 predicted later Internalizing (R^2 = .08; p =.006) and Externalizing Problems (R^2 = .07; p =.009). ***(2) Cognitive Outcomes*** revealed mean WISC-V index scores within average limits for both groups, who differed only on the Processing Speed Index (PSI; Non-ASD *M* = 99.9; ASD *M* = 87.0; p =.001). The strongest predictor of PSI performance was age 2 Mullen Visual Reception (VR; R^2 = .12 for Non-ASD; p = .02 and R^2 = .36 for ASD; p = .006), with a trend toward 12-month Mullen VR as a predictor (both group p's = .07). For both groups, 2-year Mullen Receptive (RL) and Expressive Language (EL) significantly predicted later Verbal Comprehension Index (VCI); p's < .02. Notably, RL (R^2 = .49) was more informative than EL (R^2 = .28) for the ASD group, whereas the opposite pattern was seen in the Non-ASD group (R^2 = .13 and R^2 = .27 for RL and EL, respectively).

Conclusions: Findings reveal mental health challenges commonly encountered by siblings of children with ASD, regardless of their own ASD outcomes. High rates of mental health challenges, despite average cognitive functioning, highlight the importance of monitoring the mental health of these HR children into middle childhood and beyond. Results highlight the potentially informative roles of temperament and both nonverbal and language abilities in early life in predicting later outcomes.

142 **207.142** Meta-Analysis of Sex Differences in Core Symptomatology in Autism Spectrum Disorder

M. T. Chen[1], *Y. P. Chang*[2] *and X. Lu*[2], *(1)School Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Autism Spectrum Disorder (ASD) has drawn the field's attention in recent decades, because of its high, quickly increasing, and disproportionate prevalence between the two sexes (e.g., 1 in every 38 males but 152 females; Autism and Developmental Disabilities Monitoring Network). To understand the sexual disparity, researchers have started investigating the various differences in physiological and psychological characteristics between males and females with ASD.

Objectives: The researchers meta-analyzed published studies, focusing on the sexual disparity in the severity of core symptomatology in ASD. Several potential moderators of the disparity, namely, symptom type, patient age, IQ, the assessment tool, diagnostic criteria, and publication year of a study, were also investigated. These moderators can hardly be studied in full in a single empirical study. The present meta-analysis therefore helps not only synthesize but also advance the literature.

Methods: A systematic literature search was performed on PsycINFO, Scopus, PubMed, and Web of Science for empirical studies written in English and comparing males and females with ASD in their symptom severity. The current study then included in total 84,718 (males) and 19,240 (females) repeated measures of symptoms of ASD for males and females respectively; the data were nested in 295 effect sizes nested in 43 independent studies consisting of 9192 males and 2412 females. The moderators of interest were coded if possible for analysis.

Results: Multilevel meta-analysis with effect sizes nested in studies indicated that males demonstrate higher severity in restricted and repetitive behavior but not in other two core symptoms of ASD or the composite severity than do females. This phenomenon was elaborated by the finding that the Autism Diagnostic Observation Schedule (ADOS) assessment specifically detects more restricted and repetitive behavior for males than for females. The same disparity does not emerge for other symptoms or other assessments. Finally, the analyses indicated to a potential age moderation effect that heightens females' composite ASD severity if they are older than 18. This result, nevertheless, did not appear for any of the three core symptoms individually. No moderation was found for IQ, diagnostic criteria, linear or quadratic publication year.

Conclusions: The results show that males with ASD demonstrate more restricted and repetitive behavior than do females with ASD, and the disparity might be attributed to using ADOS as the assessment tool. Further, different from what the literature suggests, patient age, IQ, the diagnostic criteria, and social-historical context of a study indicated by its publication year do not seem to influence differences in symptom severity between males and females with ASD.

143 **207.143** Mis-Diagnosis, Overdiagnosis, and the Unintended Consequences of Prevention: Interpreting the Uspstf Autism Screening Report

E. Hickey[1], *S. Broder-Fingert*[1,2], *J. Goupil*[1] *and R. C. Sheldrick*[3], *(1)Boston Medical Center, Boston, MA, (2)Boston University School of Medicine, Boston, MA, (3)Boston University School of Public Health, Boston, MA*

Background: In 2016, The U.S. Preventive Services Task Force (USPSTF) concluded "insufficient" evidence to support universal primary care screening for autism spectrum disorder (ASD). The statement led to controversy among research and clinical communities. Although a number of papers have since been published arguing for the potential benefit of ASD screening, none specifically address potential harms of ASD screening. This evidence gap may relate to confusion regarding how the USPSTF measures and evaluates potential harm.

Objectives: In the current study, we reviewed how the USPSTF operationalizes "harm," and explored how that definition impacts ASD screening

Methods: We reviewed the 18 reports released by the USPSTF between 2016 and 2018 that were issued an "I" (insufficient evidence) statement to explore: 1) how harms were operationalized, and 2) how often harms were concretely measured in the literature. We then applied this framework to the example of ASD screening

Results: We identified two categories of harm that relate to ASD screening: (1) classification error and (2) overdiagnosis. Screening classification error, defined by the National Academy of Medicine as the failure to establish an explanation of a patient's health problems in a timely and accurate manner, or the failure to communicate such an explanation, is commonly assessed by testing sensitivity and specificity of screening tools. Because an ASD diagnosis is based on screening for a range of developmental difficulties, screening can lead to false positive and false negative errors. These errors can lead to harm in a number of ways, for example by exposing families to stigma and unnecessary services, or by delaying other needed services through inappropriate reassurance.

Distinctly, overdiagnosis refers to diagnoses that are technically correct but that will not provide benefit to the patients who receive them. The

USPSTF explicitly expressed concern about overdiagnosis related to screening for skin cancer in asymptomatic adults and breast cancer in women over 75 based on evidence that screening might detect patients who met diagnostic criteria but were unlikely to benefit from treatment. Factors hypothesized to contribute to overdiagnosis in ASD include dissemination of screening to asymptomatic populations, growing awareness and an accompanying reduction in stigmatization, improvement of diagnostic procedures and changes in the diagnostic criteria, and the potential for biased clinical judgment (Merten et al., 2017). Some children who correctly meet diagnostic criteria for ASD diagnosis could have a phenotype that is less responsive to autism supports and services, thereby exposing them to the harms associated with these treatments (e.g., being pulled from class) without the benefits.

Conclusions: USPSTF screening conclusions can be better understood by clearly delineating possible causes of harm. While screening is likely to help children who are subsequently diagnosed with ASD and benefit from treatment, data on patients who receive no benefit from an accurate ASD diagnosis are severely lacking. More research on the potential harms of ASD screening is needed at the individual- and population-level. Clarity on these subjects can help inform interpretation of and response to future USPSTF reports.

144 **207.144** Missed Diagnosis of Autism Spectrum Disorder (ASD) in a Psychiatric Population

E. Block[1], *C. Colombi*[2] *and M. Ghaziuddin*[3], *(1)University of Michigan, Ann Arbor, MI, (2)Psychiatry, University of Michigan, Ann Arbor, MI, (3)University of Michigan, Ann Arbor, Ann Arbor, MI*

Background: Autism spectrum disorder (ASD) is a severe handicapping condition often diagnosed by 5 years of age. To a considerable extent, its timely diagnosis determines its long-term outcomes (Rogers et al., 2018). However, in the presence of comorbid psychiatric disorders, its diagnosis can be delayed. Relatively little is known about the risk factors that delay the diagnosis of ASD.

Objectives: To examine the characteristics of children admitted to a psychiatric unit in whom the diagnosis of ASD was missed.

Methods: Children with suspected ASD were recruited from a consecutive series of 991 patients admitted to a short-term 14-bed academic child and adolescent psychiatry inpatient unit over a two-year period. Diagnosis of ASD and comorbid psychiatric disorders was made by a multidisciplinary team.

Results: 14 children (aged 9-17 years) with suspected ASD were identified out of which eight received a final diagnosis of ASD. 13 (93%) had received at least one psychiatric diagnosis. None of the patients had intellectual disability. The most common psychiatric diagnoses initially diagnosed in this sample were ADHD (n=7); Depression (n=6); Anxiety Disorder (n=5); Aggression/Impulse Control Disorder (n=4); and one each of Bipolar Disorder, Psychosis, and Obsessive-Compulsive Disorder. Multiple psychiatric comorbidity was a common characteristic of the children with a missed diagnosis of ASD.

Conclusions: Children with multiple psychiatric symptoms beginning early in life should be screened for ASD.

145 **207.145** Mobile Computer-Mediated Assessment of Autism Risk By Non-Specialists in Home Settings: Insights from the START Project

I. Dubey[1], *M. Belmonte*[2], *T. Gliga*[3], *R. Bishain*[4], *J. Dasgupta*[5], *D. Mukherjee*[6], *S. Bhavnani*[6], *T. Tavassoli*[1], *G. Estrin*[7], *M. H. Johnson*[8], *S. Chandran*[4], *V. Patel*[9], *S. Gulati*[10], *G. Divan*[11] *and* ***B. Chakrabarti***[1], *(1)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Com DEALL Trust, Bangalore, India, (3)Psychology, University of East Anglia, Norwich, United Kingdom, (4)Computer Science and Engineering, Indian Institute of Technology, Bombay, India, (5)Sangath, Delhi, India, (6)Centre for Chronic Conditions and Injuries, Public Health Foundation of India, Gurgaon, India, (7)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (8)Department of Psychology, University of Cambridge, Cambridge, United Kingdom, (9)Department of Global Health and Population, Harvard Medical School, Boston, MA, (10)Child Neurology Division Department of Pediatrics, All India Institute of Medical Sciences, Delhi, India, (11)Sangath, Bardez, Goa, India*

Background: In many parts of the world with poor access to clinical expertise, a large number of children on the autism spectrum remain undetected, and hence are deprived of early interventions. Even those who are diagnosed experience significant delays between parents' noticing atypicalities in behaviour and specialist clinical diagnosis. To bridge this detection gap, we have developed START ("Screening Tool for Autism Risk using Technology"), a tablet-based app usable by minimally-trained non-specialist workers in home settings. START presents a range of tasks as simple games for an evaluation of social, motor, sensory, and cognitive function in 2-7-year-old children.

Objectives: To conduct a proof-of-principle study with START, administered by non-specialist workers in and around Delhi, India, using a case control study design comprising three groups of children: those with autism spectrum disorders (ASD), intellectual disabilities (ID), or typically developing (TD) children.

Methods: Non-specialist workers tested 127 children with ASD (n=46), ID (n=38) and TD (n=43), aged 2-7 years in their homes. We present data on three sets of measures: (1) *social motivation* measured using a) *preferential looking task*: tablet-based eye-tracking to measure distribution of overt attention between a social and a non-social stimulus, and b) *choice task*: to measure preference for social rewards; (2) *sensory interests* were measured by showing children a video of a spinning wheel which they could stop at will; and (3) *motor following task:* where participants were asked to follow with their finger the trajectory of a butterfly moving in a predetermined random manner.

Results: (1) In the preferential gaze task, children with ASD spend significantly (Figure 1, top left) less time looking at the social stimuli than the TD group ($F(2, 104) = 4.21$, $p = 0.017$) but in the choice task (Figure 1, top right) the groups do not differ in their choice of the social stimulus ($F(2, 98) = 0.58$, *ns*). (2) Children with ASD spend significantly longer looking at a spinning wheel than TD ($F(2, 81) = 19.57$, $p < .001$). (3) Children with ASD execute the motor following task with significantly greater spatio-temporal mean squared errors than do TD or ID groups ($F(2, 78) = 19.36$, $p < .001$).

Conclusions: This study provides proof of principle for START, revealing the expected pattern of ASD-TD group differences in relevant tasks. It also demonstrates the feasibility of such mobile scalable testing of neurodevelopment by non-specialists in home settings.

146 **207.146** Mothers with a History of Anxiety/Depression Report Higher Prevalence of Behaviors and Sensory Sensitivities: A Group-Matched Study Comparing Maternal Reporting of ASD Symptoms

S. C. Boland[1], ***J. S. Jurayj***[2], *T. Winkelman*[3], *R. J. Jou*[4], *J. Wolf*[3] *and J. McPartland*[3], *(1)Yale Child Study Center, New Haven, CT, (2)Yale Child Study Center, Yale University, New Haven, CT, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Yale University, New Haven, CT*

Background: Parent report is central to clinical assessment of ASD, yet the influence of parent characteristics, such as depression and anxiety, on report of symptomatology is poorly understood. Maternal depression has been associated with increased symptoms on parent report measures but not clinician-administered measures (Bennett et. al., 2012). Parental psychiatric symptoms negatively correlate with parental expectations for children with ASD (Thomas et al.; 2017). Given heightened prevalence of depression and anxiety among parents of children with ASD and the reliance on parent report in clinical evaluation, it is essential to understand the influence of maternal anxiety and depression on parental report of presenting concerns and clinical and behavioral features of ASD.
Objectives: To investigate the relationship between maternal anxiety and depression and parent reporting in terms of frequency of reporting specific behaviors and symptoms.

Methods: The study entailed chart abstraction of 40 individuals with ASD, aged 3-18, seen at an autism clinic. Twenty mothers self-reported a history of anxiety and/or depression (mean child age=7±2.3years), and twenty did not report anxiety or depression (mean child age=7±2.5years). Child clinical characteristics included age, ADOS severity score, IQ, and Vineland Adaptive Behavior Scales-II (VABS). A parent intake questionnaire, completed by the mother or both parents, provided information on family history, sensory function (avoids/seeks loud noises, bright lights, being touched, or certain food textures), maladaptive behaviors (screaming, hitting, biting, tantrums, self-injury, elopement), autism-related behaviors, and presenting concerns.

Results: The two groups did not differ significantly on age, ADOS calibrated severity score, IQ, or VABS subdomains or adaptive behavior composite. Mothers with a history of anxiety and/or depression reported more problem behaviors (M=2.90, SD=1.52) than mothers without anxiety and/or depression (M=1.75, SD=1.77; t=2.10, p=.048). In addition, mothers with a history of anxiety and/or depression (M=5.95, SD=2.91) endorsed more sensory sensitivities than mothers with no anxiety and/or depression (M=3.8, SD=2.21; t=2.39, p=.023). To further examine sensory sensitivities, we analyzed a parent report of autism-related behaviors, which used a 5-point Likert scale. Mothers with a history of anxiety and/or depression indicated their children were more frequently upset by loud noises (M=2.70, SD=1.22) than mothers without anxiety or depression (M=1.20, SD=.775; t=4.439, p<.001). Additionally, mothers in the anxiety and/or depression group reported their children were more frequently overly preoccupied with details (M=2.00, SD=1.41) than mothers in the control group (M=1.07, SD=1.1; t=2.12, p=.042).

Conclusions: There have been few studies to examine the relationship between maternal anxiety and depression and parent report of ASD symptoms. In the current study, despite comparable ratings on clinician-administered and structured parent interviews, parental report on a questionnaire indicated increased report of autism symptoms among parents with anxiety or depression. This topic requires further investigation in studies designed to tease out potential influencing factors, such as reporting bias or enhanced attention to detail, that may account for these differences. Ongoing qualitative analysis of open-ended responses in the current sample will provide additional information about use of emotional language in parent report.

147 **207.147** Network Structure of the ASD Phenotype Reveals Both Expected and Novel Relationships in a Large Community Sample

L. S. Cubit[1,2], *J. Pandey*[3], *R. T. Schultz*[3] *and B. Tunc*[2], *(1)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY, (2)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Autism Spectrum Disorder (ASD) is characterized by significant heterogeneity within core symptom domains (social communication and repetitive and restricted behaviors). Heterogeneity is often further compounded by comorbid conditions such as anxiety and attention deficits, as well as by impairments in other domains such as executive functioning and language expression and function. Insights into the complex interplay between behavioral domains is crucial to understand mechanisms underlying ASD heterogeneity.
Objectives: To reveal network structure of ASD phenomenology, depicting relationships between social communication, restricted/repetitive behaviors, and other domains of functioning commonly impaired in ASD. To quantify network characteristics that describe connections among these domains in ASD.

Methods: Our sample consisted of 449 participants (91% male, ages: 5-18 years, mean[SD] age: 10.2[3.0] years, mean[SD] Full Scale IQ: 94.7[22.6]) with community diagnoses of ASD. Standardized measures commonly used to assess behavioral functioning of children with ASD were used, including parent-report questionnaires assessing ASD symptoms, executive functioning, adaptive skills, language and communication, attention and hyperactivity/impulsivity, anxiety, and sleep habits, as well as clinician-administered gold-standard diagnostic tools and cognitive assessments. An undirected network representation of measures was constructed, with nodes representing the scales of the measures and edges encoding partial correlations between the scales. The data was processed with a nonparanormal transformation to calculate nonparametric correlations due to non-normal distributions of scales. Network estimation was performed using the graphical LASSO algorithm which yields partial correlations between any two given scales that are controlled for the influence of all the other scales. The extended Bayesian information criterion was used for optimal parameter selection. Three graph indices were computed to quantify topology of the network: betweenness centrality, closeness centrality, and node strength.

Results: The network structure (see Figure 1) indicated only a few strong connections (partial correlation r > 0.1) between the two core ASD domains (social communication and restricted/repetitive behaviors). Connections between these domains were primarily established through measures that assess both domains (e.g. SRS-2, ADI-R). Repetitive behaviors were directly connected to executive functioning through a connection between preference for sameness and the executive skill of shifting (r=0.19). The social anxiety scale, with high centrality indices (z-scores: closeness=1.52, betweenness=2.17), acted as a bridge between other anxiety scales and social functioning. Connections between ADHD symptom domains and core ASD domains were predominantly established through executive functioning or higher-level aspects of language use. Intellectual functioning was primarily linked to language and communication variables, but not to social functioning. Social communication had high centrality (z-scores: closeness=1.69, betweenness=1.58) and high strength (z-score=1.59), reflecting its core role in ASD.

Conclusions: Our results provide insights into the complex interplay among ASD symptoms and co-occurring impairments. Identified links between core symptom domains are consistent with current conceptualization of ASD phenomenology. Novel findings on connections between executive functioning, repetitive behaviors, language, anxiety, and social functioning may define testable hypotheses regarding causal mechanisms of ASD symptomatology.

148 **207.148** Objective Measurements of Social Visual Engagement Predict Parental Impressions of Child Behavior in a Clinical Sample

***T. A. Ponzo**, A. I. Mendez, A. Klin, C. Klaiman, S. Shultz and W. Jones, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background:

Parents have unique insights into their children's development: their daily interactions provide experiences beyond lab or clinic that form impressions distinct from those of trained clinicians in a single appointment. Although clinician best estimate remains the gold standard for diagnosis of autism spectrum disorder (ASD), parents contribute critical insights that impact initial screening, symptom profile reports, and medical histories. Despite these strengths, parental impressions are inherently subjective, based on relatively small "samples" – i.e., parents' own children rather than the many hundreds to which clinical professionals are exposed. Here, we measure the extent to which parent-report measures can be predicted by performance-based measures of social visual engagement collected via eye-tracking. These measures offer an assessment of the real-world validity of lab-based eye-tracking measures as well as the potential for objective metrics of child behavior.

Objectives:

To determine the extent to which parent-report measures of social-emotional functioning in children can be predicted by performance-based, objective measures of children's social visual engagement collected via eye-tracking.

Methods:

Participants were N=146 consecutive referrals (ages 1.1–4.75 years) to a community diagnostic clinic. Referrals were made based on concerns for ASD or other developmental delays. Parents completed the *Ages & Stages Questionnaires: Social-Emotional, Second Edition* (ASQ:SE-2), a questionnaire commonly used to identify early signs of social-emotional difficulties. Children viewed video scenes of age-matched peers engaging in naturalistic social interactions while eye-tracking data were collected. Percentage of fixation time to faces was calculated for each participant. We then used hierarchical logistic regression to predict parent responses on the ASQ:SE-2 from children's eye-tracking measures.

Results:

Eye-tracking-based measures significantly predict ASQ:SE-2 parent responses. Items more relevant to social visual engagement (e.g., *Does your child look at you when you talk to him?; Is your child interested in things around her, such as people, toys, and food?*) are more strongly associated (r=0.406, p<0.001 and r=0.359, p<0.001, respectively), while items less relevant were unrelated (e.g., *Does your child hurt himself on purpose?*; *Does your child try to hurt other children, adults, or animals?*, both r<0.01, p>0.05). Hierarchical logistic regression yielded parameter estimates modeling (a) the odds of a child rarely or never looking at a parent's face when talking (versus looking sometimes or most times) and (b) the odds of a child looking at least sometimes (versus most times) [Figure 1]. In both cases, *t* and *p* values indicate that eye-tracking-based measures significantly predict the odds of a child's real-world behavior (*t*>2.6, *p*<0.01): for every 1% *decrease* in eye-tracking-based measures of face-looking, the model indicates a 15% increase in the odds that a child rarely or never looks at a parent's face; likewise, every 1% decrease in face-looking indicates a 6% increase in the odds that a child looks only sometimes [Figure 2].

Conclusions:

Objective measures of face-looking are significantly associated with parental impressions and predict specific aspects of a child's social-emotional functioning. These results highlight the real-world relevance of lab-based eye-tracking measures and offer potential for capitalizing on measures that converge with the unique insights gleaned from parents.

149 **207.149** Objectively Measured Social Communicative Behaviors during the ADOS-2

***Y. A. Ahn**[1], J. M. Moffitt[1], J. Durocher[2], M. N. Hale[2] and D. S. Messinger[2], (1)Psychology, University of Miami, Coral Gables, FL, (2)University of Miami, Coral Gables, FL*

Background: Autism spectrum disorder (ASD) is defined in part by persistent disturbances of social communication and interaction, such as eye contact (social gaze), facial expressions (smiles), and vocal turn-taking. In current best practice, ASD is recognized on the basis of expert clinician judgment, which is informed by gold-standard measures such as the Autism Diagnostic Observation Schedule-2 (ADOS-2; Lord et al., 2012). To date, observational research addressing social communication disturbances in children with ASD is rare in part because the field has lacked efficient methods for measuring behavior (Chin et al., 2018, Rehg et al., 2014, Swanson et al., 2017). Yet, improving social communication and reducing interaction disturbances depend on an objective understanding of how children with ASD behave during clinical assessments. The current study aims to improve objective understanding of social communicative behaviors among children with ASD during the ADOS-2.

Objectives: To investigate associations between objective measures of child's social gaze and social smile measured from adults' first-person video, child-adult vocal interaction measured from audio recording, and the traditional examiner-scored symptom measure ADOS-2 calibrated severity scores (CSS).

Methods: Fifteen children (*M* age=35.93mo, SD=6.61) were administered the ADOS-2 assessments. The ADOS-2 yields a total CSS as well as subscales for Social Affect (SA CSS) and restricted/repetitive behavior (RRB CSS). Children's total duration of smiles, socially-directed smiles, and social gaze during the assessment were recorded with a small Pivothead camera worn in glasses by the examiner and the parent. iMotions software was used to detect child smile expressions and gaze during the assessment as recorded on the parent and examiner Pivothead camera. Audio from wall-mounted camera recordings was processed with a Language ENvironment Analysis (LENA) software, which provided automated vocalization detection yielding child and adult vocal initiation counts and turn counts within conversational vocal blocks. Measures included proportion of gaze and smile at examiner and parent, total duration of gaze and smile at adult, rate of child and adult vocal initiation, and ADOS-2 CSS (total, SA, and RRB).

Results: The mean duration of smiles recorded by both examiner and parent head-mounted cameras was negatively associated with the total CSS (*r*=-.53, *p*<.05) and RRB CSS (*r*=-.52, *p*<.05), but not significantly associated with SA CSS (*r*=-.39, *p*>.05). The association between the proportion of gaze at the examiner and the total CSS was marginally significant (r=-.493, p=.06). Higher RRB CSS was significantly correlated with lower proportion of gaze (*r*=-.62, *p*<.05) and social smile (*r*=-.62, *p*<.01) at the examiner. In boys (n=11), more adult vocal initiation was associated with fewer smiles at examiner (*r*=-.67, *p*<.05), but this association was not significant for the group as a whole.

Conclusions: Objective measurements of children's smiles and gaze during the ADOS-2 converge with examiner-scored ADOS-2 calibrated severity scores. Although these dimensions of social communication are indexed by ADOS-2 SA CSS, objectively measured social behaviors were unexpectedly associated with RRB CSS, which may limit social interaction. The objective measurement of key behavioral features of ASD appears

to have the potential to produce quantitative indices of ASD symptoms.

150 **207.150** Parent-Teacher Discrepancy in Ratings of Executive Functioning in Black and White Children with ASD

S. I. Habayeb[1], *L. Kenworthy*[1], *S. Rau*[1], *M. Miller*[1], *A. C. Armour*[1], *K. D. Csumitta*[2] *and A. B. Ratto*[1], *(1)Children's National Health System, Washington, DC, (2)National Institutes of Health, Bethesda, MD*

Background: Racial based reporting biases have been found, wherein teachers report higher rates of externalizing symptoms in Black children than parents do (Harvey et al., 2013), and than reported for White peers (Lau et al., 2004). In children with Autism Spectrum Disorder (ASD), increased discrepancy between parent and teacher report on standardized questionnaires can affect clinical characterization and subsequent treatment involvement (Lerner et al., 2017). While some research has explored parent reported differences in executive functioning (EF) across race (Ratto et al., 2016), research has not yet explored the impact of parent-teacher discrepancy on the characterization of these skills.
Objectives: To explore parent-teacher discrepancy in ratings of EF across race.

Methods: Data were collected from 284 children with ASD as part of neuropsychological evaluations at an academic medical center (N=1290). Full-scale IQ (FSIQ) was determined using standardized intelligence measures (Table 1). Parent and teacher forms of the Behavior Rating Inventory of Executive Function (BRIEF; Gioia, Isquith, Guy, & Kenworthy, 2000) were used to assess EF skills yielding T-scores. To assess parent-teacher discrepancy, difference scores were calculated (parent – teacher; Figure 1). Regression analyses (including age and FSIQ) explored whether race predicted parent-teacher discrepancy, parent, and teacher ratings of EF.

Results: Controlling for age and FSIQ, significant discrepancies were found between parent and teacher report for ratings of Black children compared to White children on the following subscales and indices: "Inhibit" (B = -5.247, p = 0.045), "Monitor" (B = -5.947, p = 0.024), "Initiate" (B = -6.140, p = 0.023), "Organization of Materials" (B = -11.649, p = 0.027), and "Meta-Cognitive Index" (B = -5.188, p = 0.047), with parents rating lower symptoms than teachers. Race significantly predicted parent report, with Black parents rating lower levels of symptoms than White parents on the following subscales: "Inhibit" (B = -5.395, p = 0.009), "Initiate" (B = -3.960, p = 0.024), "Plan/Organize" (B = -4.147, p = 0.028), "Organization of Materials" (B = -3.625, p = 0.040), "Monitor" (B = -5.346, p = 0.004), "Behavior Regulation Index" (B = -4.105, p = 0.033), "Meta-Cognitive Index" (B = -4.227, p = 0.014) and "Global Executive Composite" (B = -4.461, p = 0.009). Race did not significantly predict differences in teacher report. Results maintained significance following a Benjamini-Hochberg procedure correction for multiple comparisons.

Conclusions: Race significantly predicted a difference in discrepancy between parent and teacher report of EF problems on several subdomains of the BRIEF. Compared to Caucasian children, teachers and parents disagreed more on EF ratings for Black children, with teachers on average indicating more impairment than parents. Upon further exploration, the discrepancy seems to be driven by parents of Black children rating lower levels of symptoms than parents of Caucasian children. Racial reporting differences were not found on behalf of teachers. Findings may indicate potential differences in symptom presentation between home and school, wherein home cultures may be better suited to meet the needs of Black children with ASD (Ratto et al., 2016) or may indicate underreporting of symptoms by their parents.

151 **207.151** Patterns of Autism Symptom Severity Change during Early Childhood

E. Waizbard-Bartov[1,2], *E. Ferrer*[1], *G. S. Young*[3], *B. Heath*[4], *S. Rogers*[4], *C. W. Nordahl*[4], *M. Solomon*[5] *and D. G. Amaral*[4], *(1)UC Davis, Davis, CA, (2)MIND Institute, Davis, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (5)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA*

Background: While Autism Spectrum Disorder is commonly considered to be stable throughout the lifespan, evidence now indicates that at least some individuals demonstrate substantial changes in symptoms and functioning over time. Assessing change in autism symptom severity is a key concern for researchers, clinicians and parents alike. Previous studies have generally shown that symptom severity remains stable over time, with small groups decreasing or increasing. However, recent papers have also indicated the possibility of substantial change in symptom severity levels.

Objectives: We used the ADOS CSS (ADOS-2: Autism Diagnostic Observation Schedule-2, Calibrated Severity Score) to evaluate the extent of change in autism symptom severity demonstrated by children diagnosed with ASD from the MIND Institute's Autism Phenome Project (APP) and Girls with Autism Imaging of Neurodevelopment (GAIN) study.

Methods: One hundred and twenty five children with ASD (89 boys and 36 girls) were assessed at approximately 3 years of age (Time 1) and again at approximately 5-6 years (Time 3) for autism symptom severity, IQ and adaptive function. A severity change score was computed by subtracting each participant's Time 1 ADOS CSS score from their Time 3 ADOS CSS.

Results: Given the wide range of severity change scores demonstrated (ranging from increase of 4 points to decrease of 6 points, Figure A), the RCI (Reliable Change Index) was used to determine what constituted significant change - this was a 2 point change. Children were divided into groups according to their demonstrated increase, decrease or stability of autism severity. Almost half the children in the sample demonstrated significant autism symptom severity change over time (Figure B). The Decreased Severity Group (28.8%) included children who decreased in severity by 2 or more points. It was characterized by a large range of individual severity scores at age 3, an over-representation of girls, higher IQ means at both times and higher adaptive functioning at Time 3 compared to other groups. The Stable Severity Group (54.4%) included children who changed by 1 point or less in either direction. It had almost identical Time 1 and 3 CSS means, equal proportions of boys and girls, made IQ gains over time but remained stable in adaptive functioning. The Increased Severity Group (16.8%) included children who increased by 2 or more points in severity. This group had the lowest mean severity scores at Time 1 but the highest at Time 3, had an under-representation of girls and showed stability in IQ and adaptive functioning.

Conclusions: Autism symptom severity can change substantially during early childhood. Patterns of change are associated with factors such as sex, IQ and adaptive functioning. The current study included a higher proportion of girls (28.8%) compared to previous studies. Since girls showed a greater tendency to decrease in severity compared to boys, this could partially explain the higher perecentage of children who decreased in severity in the current study. This work can be relevant for families, professionals and researchers as it helps guide expectations for long-term outcome.

152 **207.152** Patterns of Symptom Severity Developmental Trajectories in Children with Autism Spectrum Disorder in Taiwan

K. C. Lin[1], *C. H. Chiang*[2], *T. L. Lin*[2], *C. C. Wu*[3] *and C. L. Chu*[4], *(1)Department of Psychology, Taipei, Taiwan, (2)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (3)Department of Psychology, Kaohsiung Medical University , Kaohsiung, Taiwan (Province of China), (4)Department of Educational Psychology & Counseling, National Pingtung University, Pingtung, Taiwan*

Background: Autism spectrum disorder (ASD) is widely known to be a highly heterogeneous neurodevelopmental disorder. Recently growing bodies of researches focused on the developmental trajectories of autism severity, which has been seen as one ofpromising waysto understand the heterogeneity of ASD and may lead to a better understanding of prognosis (Baker, Smith, Greenberg, Selzer & Taylor, 2011). However, seldom longitudinal studies have been conducted in the East, and none in Taiwan. Therefore, it highlights the necessity of the investigation.
Objectives: The purpose of this study is (1) to explore the subgroups of autism severity in the children with ASD from toddlers to school age in Taiwan, (2) and further characterize these subgroups by cognitive and adaptive functions.

Methods: Seventy ASD participants were assessed at three time points from toddlerhood to school age (mean age: T1 = 35.11 months, T2 = 55.11 months, T3 = 109.17 months) across 6 years. The standardized assessments were used to measure autistic total symptoms severity (ADOS calibrated severity score [CSS]), cognitive functions (MSEL, WPPSI-IV or WISC-IV) and adaptive functions (VABS-II). The hierarchical cluster analysis collocated with two-way mixed designed ANOVA were conducted to identify the subgroups of three time points ADOS-CSS. The comparison of cognitive and adaptive functions between subgroups were showcasedby one-way ANOVA.

Results: In hierarchical cluster analysis, three subgroups were identified including “worsening group” (n = 43), “persistent high group” (n = 18), and “improving group” (n = 9). All groups improved on FSIQ, but the worsening and improving groups show significantly higher progress than does the persistent high group (p = .016*). The improving group has higher but no significant difference in T1 FSIQ (p = .060). In T3, the improving group has the highest cognitive outcome (p= .001**). In terms of adaptive functions, three groups show significant differences in Vineland adaptive behavior composite (improving > worsening > persistent high; p = .000***). The improving group has the best performance in the communication (improving > worsening > persistent high; p = .000***) and daily living skill (improving > worsening = persistent high; p = .005**) domains, but not in the socialization domain (improving = worsening > persistent high; p = .000***).

Conclusions: Similar to western findings, the development of autism severity can bedivided into three groups. Each group is characterized by different cognitive and adaptive functions, which shows total symptoms severity is a valid indicator for Taiwanese children with ASD. Three groups have similar FSIQ in toddlerhood, and all of them show improvement over time. But the greater improvement in the improving and worsening groups might contribute different outcomes in school age, of which the improving group has the highest FSIQ, followed by the worsening group, and the persistent high group, which has the lowest FISQ. The improving group also shows the best performance in adaptive functions in school age; however, the advantage mainly appears in the communication and daily living skill domains, but not in the socialization domain, which might reflect the existence of ASD social deficit.

153 **207.153** Perspectives of Autistic Adults, Relatives and Clinicians on the Characteristics of Current and Optimal Post-Diagnostic Support Services

S. Wigham[1], *B. Ingham*[2], *A. LeCouteur*[3], *T. Berney*[3], *C. Wilson*[4] *and J. R. Parr*[5], *(1)Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: there are few post-diagnostic support services available for autistic adults. Service developments are required to address this significant unmet need.
Objectives: (1) to explore the characteristics of current UK post-diagnostic support services from the perspectives of autistic adults diagnosed in the last 5 years, relatives and clinicians and (2) compare these characteristics with views about optimal services and the recommendations made in the UK NICE guidelines (2012) and (3) identify specific areas that require development to create optimal post-diagnostic support services.

Methods: 346 adults with a clinical diagnosis of an autism spectrum disorder completed a national survey about their experiences of the post-diagnostic process, and possible adjustments; 46 relatives completed a parallel survey. 36 UK diagnostic teams were surveyed to capture the characteristics of current post-diagnostic services, and suggestions about modifications. A modified Delphi survey process was used to seek consensus on the characteristics of optimal post-diagnostic services. Data analysis comprised content analysis, descriptive statistics, tests of correlation, difference and agreement.

Results: the median age of autistic adults was 44 years (and 41 years at diagnosis, range 18-89); 54% of respondents were female. Two thirds reported a mental health condition (55% anxiety; 54% depression). Almost all adults and relatives reported that feedback after the diagnostic assessment was received. Only 56% reported opportunities to discuss what support might be beneficial, and 51% had the opportunity to discuss their strengths or the impact of the diagnosis on relationships or work. Clinical consensus was reached on 11 statements describing characteristics of optimal post-diagnostic support services. All clinical teams agreed that offering an extra ‘follow-up meeting at 2-4 months after the feedback meeting to discuss implications of diagnosis, coping strategies and future planning’ should be a characteristic of optimal post-diagnostic support services. 50% of clinical teams did not have the resources to treat co-morbid mental health conditions identified during the diagnostic assessment (this aligned with the experiences of the autistic adults surveyed); and 47% of clinical teams reported they were unable to provide any further support or preventative interventions for those not in crisis. Diagnostic teams agreed that ‘a diagnosis of autism should not limit access to community and/or inpatient mental health services.’ Teams also agreed that optimal post-diagnostic services ‘should include occupational therapists and speech and language therapists’ and opportunity to access ‘step-on/step-off’ support to protect mental health, and maintain well-being. Consensus was that optimal post-diagnostic services should include people in the core team with expertise in autism, from multiple agencies/specialities, and that training other parties on the treatment of co-existing conditions should be commissioned and resourced (in partnership with other agencies) as opposed to being ad hoc.

Conclusions: service users and clinicians all identified gaps in current post-diagnostic support. Clinical teams achieved full consensus on the characteristics for optimal autism post-diagnostic support service developments. These findings can inform the necessary developments. Optimal services need commissioning, and some reorganisation of resources is required. Service structures and policy specifications should be developed to best support the well-being of autistic adults, relatives and clinicians.

154 **207.154** Piloting "Autoscreen": Preliminary Results of a Novel Digital Tool for Clinically Efficient Assessment and Decision Making for Toddlers with ASD Concerns

J. W. Wade[1], *A. Swanson*[2], *A. S. Weitlauf*[3], *Q. Humberd*[4], *N. Sarkar*[1,5] *and Z. Warren*[6], *(1)Adaptive Technology Consulting, Murfreesboro, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Independent Consultant, Nashville, TN, (5)Vanderbilt University, Nashville, TN, (6)Vanderbilt University Medical Center, Nashville, TN*

Background: Early accurate identification of young children with Autism Spectrum Disorder (ASD) represents a pressing clinical care challenge. Current AAP practice guidelines endorse ASD screening at 18 and 24 months of age, followed by referral and evaluation for those at-risk by qualified providers. At present, a variety of resource barriers exist, resulting in large numbers of children not being screened and prolonged waits for diagnostic assessments. Consequently, the average age of diagnosis in the US remains between 4 and 5 years of age.
Objectives: Based on advanced computational analysis of a large sample of toddlers receiving gold-standard evaluations for ASD and a dynamic design process involving leading diagnostic experts at partner academic institutions, we created a stand-alone screening application designed to present community pediatric providers with a 15-minute ASD risk assessment method (i.e., a structured interaction via app-based instructions and in-app rating system of ASD symptoms).

Methods: This pilot study included 18- to 36-month-old children (n = 24) clinically referred for ASD evaluation as well as professionals and paraprofessionals (n = 24) licensed to conduct clinical ASD evaluations (e.g., pediatrics, clinical psychology, and speech-language pathology). Each provider used Autoscreen to assess a different child. Immediately afterward, a different blinded provider conducted a full diagnostic evaluation for the child. Meanwhile, the Autoscreen provider entered behavioral codes into Autoscreen and a risk index was automatically computed.

Results: Participating professionals favorably regarded our functionally robust prototype. Providers reported (a) excellent usability of the tool (System Usability Scale mean = 87.36), (b) high acceptability of the tool (Acceptability, Likely Effectiveness, Feasibility, and Appropriateness Questionnaire mean = 87.28), (c) and 88% agreement with Autoscreen's dichotomous risk index (i.e., high versus low risk) using the *a priori* predictive model. Based on a receiver-operating characteristic (ROC) analysis, a comparison of predicted ASD risk by Autoscreen with best estimate clinical diagnoses presented encouraging evidence of Autoscreen's potential as an instrument for reliable ASD risk classification. Levels of accuracy, sensitivity, specificity, and other performance metrics demonstrated the potential of Autoscreen to compete with established screeners while simultaneously addressing several pain points of providers. Although quite preliminary, an observed accuracy of 79%, sensitivity of 0.77, and specificity of 0.86, outperform many commonly used screening instruments.

Conclusions: Ultimately, we hypothesize that Autoscreen could powerfully enhance early identification of children with ASD and improve provider confidence around risk assessment and referral decisions. Although these early results are promising, there are a few key areas in which Autoscreen must be improved—both in terms of risk classification and technological enhancement—before it could be considered ready for real-world deployment. Most notably, a larger, higher-powered study capable of evaluating reliability metrics is required to demonstrate Autoscreen's credibility as an impactful clinical tool. Such a study is part of planned future work.

155 **207.155** Positive Predictive Value of the Modified Checklist for Autism in Toddlers, Revised with Follow-up for Black and White Children

Y. G. Dai[1], *K. Porto*[1], *D. L. Robins*[2] *and D. A. Fein*[1], *(1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Early diagnosis and intervention improve outcomes for children with Autism Spectrum Disorder (ASD) (Baird et al., 2001; MacDonald, Parry-Cruwys, Dupere, & Ahearn, 2014). However, Minority children are typically diagnosed substantially later than White children, despite similar prevalence and symptom severity (CDC, 2006; Fombonne, 2003). To reduce this gap, universal screening has been proposed as a way to identify *all* children at risk for ASD early. However, limited research exists exploring the effectiveness of ASD-specific screening tools between racial groups, particularly Black versus White children. Studies that have done this combine across racial minority groups, thereby potentially precluding identification of meaningful differences (e.g., Khowaja, Hazzard, & Robins, 2015; Scarpa et al., 2013).
Objectives: We compared the positive predictive value (PPV) of the Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R/F; Robins et al., 2014) for Black and White children who screened positive at 18-month well-child visits. Sensitivity and specificity were not measurable in this sample, given that all screen negative cases were not evaluated.

Methods: Participants were 310 children ages 16-21 months, evaluated as part of a larger study on the early detection of ASD. Children who screened positive on the M-CHAT-R/F at their 18-month pediatric well-child care visit were offered a free developmental and diagnostic evaluation by a licensed clinical psychologist or a developmental-behavioral pediatrician and a doctoral student. M-CHAT-R/F PPV for (a) ASD and (b) any developmental disorder was compared for 128 Black and 182 White children. Racial groups were also compared on monthly household income, which was used as a proxy for socioeconomic status.

Results: Racial groups (Black, White) differed on monthly household income (Black group monthly income M = \$2,498, SD = \$2,453; White group M = \$5,838, SD = \$2,837), t (241) = 9.74, p < .001. However, M-CHAT-R/F PPV for ASD was similar for Black (PPV = 0.445, CI = 0.37 – 0.53) and White (PPV = 0.431, CI = 0.37- 0.50) children (χ^2(1, N = 310) = 0.0736, p = .79). The PPV for any developmental diagnosis (i.e., ASD, Language Disorder, or Global Developmental Delay) was higher for Black children (PPV = 0.890, CI = 0.83 – 0.93) than for White children (PPV = 0.809, CI = 0.75 - 0.86), χ^2(1, N = 310) = 4.4707, p = .03).

Conclusions: We explored the predictive utility of the M-CHAT-R/F in detecting Black and White children at risk for ASD and other developmental delays based on an 18-month positive screening. PPV for ASD was similar between the two racial groups and consistent with previously reported values, yet the M-CHAT-R/F appeared to be slightly better at detecting any developmental disorder in Black toddlers. This is one of few studies to specifically compare M-CHAT-R/F performance for Black and White children and suggests that the screener performs adequately irrespective of child race.

156 **207.156** Prediction of Maladjustment Trajectories during Elementary and Junior High School with Symptoms of ASD Assessed in Preschool

M. Tsujii[1] *and H. Ito*[2], *(1)Department of Sociology, Chukyo University, Toyota, JAPAN, (2)Department of Contemporary Education, Chubu University,*

Kasugai, Japan

Background: It is important to understand ASD symptoms in early childhood, especially in naturalistic contexts. If a preschool teacher can easily grasp the ASD characteristics of the child, that will enable to start developmental supports in early stages of the childhood. We developed Transitional Assessment Sheet for Preschoolers (TASP) which is a screening tool that preschool teachers can easily grasp the state of preschool children, TASP can grasp not only ASD symptoms but also ADHD symptoms and DCD symptoms. While studying the long-term course over 10 years in our cohort study, we examined the relationship among ASD symptoms which had grasped by preschool teachers and the adaptation in their adolescent.

Objectives: We examined how the ASD characteristics of children in early childhood grasped by TASP influences the adaptation to school and mental health in their elementary and junior high schools in our cohort study.

Methods: The sample comprised 3,717 participants (1,908 boys and 1,809 girls) of our cohort study investigated annually for 10 years between the 3rd grade of preschool (age 5 or 6) and 3rd grade of junior high school (age 14 or 15). We examined 3 kinds of developmental disorder symptoms (ADHD, ASD, and DCD) assessed at preschools as predictors of developmental trajectories of 4 maladjustment variables (academic failure, peer problems, internalizing problems and externalizing problems) during 9 years in elementary and junior high schools using the conditioned latent growth model. Developmental disorder symptoms were rated by preschool teachers using our original scale, TASP. TASP consists of 35 items from 7 subscales (Hyperactivity/Impulsivity, Inattention, Social Interaction, Communication, Inflexibility, Fine Motor, and Gross Motor) and its reliability and validity were examined from various aspects (internal and test-retest reliability and factorial, concurrent and predictive validity). Socio-emotional maladjustment was rated by teachers of elementary and junior high school using Strengths and Difficulties Questionnaire (SDQ), an internationally used scale for assessment of emotional and behavioral problems. Academic achievement was measured with Kyokenshiki Norm-Referenced Test, a standard achievement test widely used in schools around Japan.

Results: The conditioned latent growth model showed the following results: (a) Level of peer problem was predicted by high hyperactivity/impulsivity, poor social interaction, and poor gross motor skills through the impact of hyperactivity/impulsivity was diminished in high graders; (b) Level of academic achievement was predicted by low hyperactivity/impulsivity, elevated inattention, poor communication skill, and poor fine motor skill though impacts of hyperactivity/impulsivity and communication were diminished in high graders; (c) Level of internalizing problem was predicted by poor social interaction, poor communication skills, elevated inflexibility, and poor gross motor skills through impacts of communication and inflexibility were reduced in high graders; (d) Level of externalizing problem was predicted by high hyperactivity/impulsivity and elevated inattention though impacts of hyperactivity/impulsivity were reduced in high graders.

Conclusions: We found that ASD characteristics, grasped by preschool teachers in early childhood using TASP, predict social isolations and depressed states in their elementary and junior high schools.

157 **207.157** Preschool Staff Spot Social Communication Difficulties, but Not Restricted and Repetitive Behaviors in Young Autistic Children

E. Nilsson Jobs[1], *S. Bolte*[2] *and T. Falck-Ytter*[3], *(1)Karolinska Institute, Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3)Karolinska Institutet & Uppsala University, Uppsala, Sweden*

Background: Clinicians sometimes visit the preschool as part of the assessment of autism spectrum disorder (ASD) in children. This could be the case when clinical findings and information from parents are insufficient for a diagnostic decision. A less costly and time-consuming source of information could be ratings of the child´s autistic behaviors by preschool staff. It has been found that preschool staff rate general autistic symptoms in children more accurately than parents. However, it is not known what kind of autistic behaviors, whether difficulties of social communication and interaction (SCI) and/or restricted and repetitive behaviors (RRBs), that preschool staff identify.

Objectives: The objective of the study was to investigate how accurate preschool staff are at reporting difficulties in SCI and RRBs in young children. The first aim was to investigate if preschool ratings of SCI and RRBs would discriminate between children with and without ASD at three years of age. We expected that ratings of both SCI and RRBs would contribute uniquely to the differentiation between the groups. The second aim was to investigate if there was a specific association between preschool ratings on SCI behavior and clinical assessment of social behavior, and between preschool ratings on RRBs and clinical assessment of RRBs. We expected a positive correlation between the corresponding measures.

Methods: Preschool staff's ratings on the SCI and RRB subscales from the Social Responsiveness Scale – 2 and the Repetitive Behavior Scale-R were compared between three-year-old siblings, having an older brother or sister with ASD, either diagnosed (n = 12; six girls) or not diagnosed (n = 36; 20 girls) with ASD, and typically developing control siblings with no family history of ASD (n = 16; seven girls). Ratings were investigated from a categorical (group status) and dimensional (preschool ratings relative to clinical assessment of autistic symptoms) perspective. All preschool staff were blind to diagnostic status and the diagnostic assessment took place independent of rating results.

Results: In line with our expectations, we found that preschool staff differentiated between the ASD group and the two other groups for SCI behaviors and that the preschool SCI ratings were significantly associated with clinical assessment of social deficits in the high-risk group. However, against our expectations, ratings of the preschool RRB subscale showed no differentiation between the ASD group relative to the two other groups. Moreover, the preschool RRB ratings did not correlate with clinical assessment of RRBs in the high-risk group.

Conclusions: Ratings of SCI behaviors by preschool staff are in line with clinical assessment and can be a valuable source in differentiating children with ASD from those who have not. However, results indicate that preschool ratings of RRBs should be interpreted with caution. More research is needed within the RRB rating field.

158 **207.158** Preschoolers with ASD Who Have Both Cognitive and Adaptive Functioning Delays: Follow-up to Age Eight

H. E. Flanagan[1], *I. M. Smith*[1,2], *T. Bennett*[3], *E. Duku*[4], *M. Elsabbagh*[5], *S. Georgiades*[4], *C. M. Kerns*[6], *P. Mirenda*[6], *P. Szatmari*[7], *W. J. Ungar*[8], *T. Vaillancourt*[9], *J. Volden*[10], *C. Waddell*[11] *and L. Zwaigenbaum*[10], *(1)IWK Health Centre, Halifax, NS, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (4)McMaster University, Hamilton, ON, Canada, (5)McGill University, Montreal, PQ, Canada, (6)University of British Columbia, Vancouver, BC, Canada, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (9)University of Ottawa, Ottawa, ON, Canada, (10)University of Alberta, Edmonton, AB, Canada, (11)Simon Fraser University, Vancouver, BC, Canada*

Background: Intellectual disability is a common co-occurring condition in individuals on the autism spectrum. Individuals with an intellectual disability have delays in both cognitive scores/IQ and adaptive functioning (typically standard scores < 70). In preschoolers, combined delays can be challenging to interpret, as standard scores often increase between preschool and school-age. Our team previously explored stability and change in cognitive and adaptive scores between age 2-4 and age 6 in a large longitudinal cohort. This study extends these findings to age 8.
Objectives: To examine developmental trajectories of children with ASD who have combined cognitive and adaptive delays at age 2-4. Specifically: (1) how do mean cognitive and adaptive scores change from age 2-4 to age 6, and to age 8 and (2), how frequently do delays (scores < 70) persist to ages 6 and 8?

Methods: Participants were 70 children from the Pathways in ASD cohort (76% boys; 33% of larger sample), recruited from one of five Canadian cities. At diagnosis, each child had both cognitive and adaptive standard scores < 70. Children were initially assessed at mean age 41.31 (*SD*= 7.96) months and reassessed at 79.15 (*SD*= 3.92) months and 104.71 (*SD*= 2.83) months. Adaptive functioning was measured using the Vineland Adaptive Behavior Scales, 2nd edition. Cognitive functioning was measured using either the Merrill-Palmer Revised (M-P-R), Wechsler Preschool and Primary Scale of Intelligence- 3rd edition (WPPSI-III) or Wechsler Intelligence Scale for Children- 4th edition (WISC-IV).

Results: (1) Between age 2-4 and age 6, mean IQ increased by 13 points (from 29.30 to 42.77, p <.001) and mean adaptive functioning increased by 4 points (from 62.31 to 65.87, p = .007). Smaller gains took place between ages 6 and 8: 6-point gain in IQ, to 48.55 (p = .003); 2-point gain in adaptive functioning, to 67.94 (p = .001). 2) At age 6, only 57% of children continued to have delays in both cognitive and adaptive functioning (see Table). In contrast, stability of skill level (combined delay vs. no combined delay) between ages 6 and 8 was high (κ = .86). At age 8, 56% had combined delays.

Conclusions: Results are consistent with clinical guidelines that suggest caution in interpreting low cognitive and adaptive scores in very young children with ASD, as scores and skill levels often improve by age 6. Stability of skill level is high between ages 6 and 8. It is also important to ensure that a diagnosis of ASD does not overshadow potential diagnosis of intellectual disability. Mean cognitive and adaptive scores remained < 70 at age 8, and over 50% of children continued to have significant impairment in both areas. During the preschool years, discussing the possibility of later intellectual disability may be appropriate. Re-assessment is important for this subgroup of children with ASD.

159 **207.159** Prevalence of Social Communication Disorder in Children at Risk for Autism Spectrum Disorder

*A. S. Ward[1], A. Boan[1], L. Carpenter[1] and **C. Bradley**[2], (1)Medical University of South Carolina, Charleston, SC, (2)Developmental-Behavioral Pediatrics, Medical University of South Carolina, Charleston, SC*

Background: In the years since the DSM-5 was released, concerns have been raised about the relationship between Social Communication Disorder (SCD) and Autism Spectrum Disorder (ASD).
Objectives: In the present study, we examined rates of DSM-5 SCD symptoms and diagnoses in youth at risk for ASD. We also compared how participants with and without diagnoses of ASD scored on the Children's Communication Checklist (CCC) in order to explore differences in social communication and pragmatic language as this might inform diagnosis of SCD.

Methods: Data for this study come from an epidemiological study examining the prevalence of ASD. Diagnostic evaluations were performed on 292 participants who had previously screened at risk for ASD via the Social Communication Questionnaire-Lifetime Version (SCQ). DSM-5 diagnoses were assigned by clinician best-estimate procedures by one of three doctoral level clinicians. Measures of autism symptoms, cognitive and adaptive skills, and behavioral checklists, including the CCC were included in assessment. The CCC was completed by all English-speaking parents whose children had at least phrase speech (n = 258) in order to measure communication and language issues common to both ASD and SCD.

Results: Out of 292 youth at risk for ASD, only 1 met diagnostic criteria for SCD. While 20 participants met all 4 clinical criteria for SCD, 19 of these (95%) also met criteria for DSM-5 Autism Spectrum Disorder, effectively ruling out a diagnosis of SCD. Analyses of the CCC scores indicated that participants with ASD also experienced impairment in scales measuring pragmatic communication (the hallmark feature of SCD) as well as impairment in the social relations and interests scales.

Conclusions: Results indicated that while a number of children met DSM-5 criteria for SCD, they were almost entirely children also meeting criteria for ASD. Further research is needed to evaluate the overlapping relationship between these disorders to inform diagnostic procedures and treatment recommendations, particularly as many the supports and services available for children with ASD may be difficult for children with SCD to access.

160 **207.160** Professional Views in Working with Children with ASD in Lithuania

***R. Buivydaite**[1], C. Newton[2] and A. Prasauskiene[3], (1)University of Oxford, Oxford, United Kingdom of Great Britain and Northern Ireland, (2)Kenya Medical Research Institute, Kilifi, KENYA, (3)Psychiatry, Lithuanian Health University, Kaunas, Lithuania*

Background: Although research on Autism Spectrum Disorder (ASD) is increasing, most studies across different nations have reported wide variation of knowledge among health and educational professionals regarding diagnosis, treatment, teaching programmes and prognosis of ASD (Eseigbe et al., 2015). Professional's knowledge of ASD, in any health or education setting, is crucial to provision of optimal services and support for the family, which reduces the burden associated with ASD for the society (Imran et al., 2011). However, lack of knowledge and consistency among the services providers create unnecessary tensions between professionals and parents that could be avoided.
Objectives: The present research was conducted to further explore the experiences of professionals and their perceptions, knowledge's and attitudes about ASD and parental stressors while raising a child with ASD in Lithuania

Methods: Due to lack of research in this area in Lithuania, the qualitative methodology was used to explore the existing issues in-depth. Professional's attitudes and perceptions were explored via focus group discussions (FGD), which are a social method of obtaining research data through informal group discussions on a specific topic. In order to maximise the diversity of experiences informing the investigation a range of professional's subpopulations were identified: general practitioner vs specialised, mainstream school teacher's vs specialised school teachers, experienced vs less experienced, highly exposed to ASD vs less exposed to ASD, knowledgeable about ASD vs novice, rural vs urban. The sample consisted of total 42 people (N=7 general practitioners, N=7 ASD medical assessors, N=8 specialised urban school teachers, N=6 mainstream rural teachers, N=7 mainstream urban teachers).

Results: The key themes mentioned across groups were: knowledge and perception of ASD; process of diagnosis, the complexity of relationship

between parents and professionals, integration, training and resources, stigma and society. There were multiple discrepancies found in aspects of care, diagnosis, education and resources, thus divided into different themes or domains concurrently. The comments reported here represent the lives of parents of a child with ASD and portrayed the difficulties and benefits they experienced while having a child with ASD in Lithuania.

Conclusions:

In summary, there was agreement between medical professionals and parents on many issues, such as the need for future improvements with regard to help after diagnosis. Also, participants agreed on the levels of stigma in Lithuanian society and how destructive it is to the families. However, there was some discrepancy in transfer of information between the medical professionals and parents for next steps after diagnosis. Knowledge of ASD symptomology in young children should be the focus of GPs to help refer children early.

Also, experiences of parents indicated the need to equip mainstream school teachers in methods to work with children with ASD. It also highlighted the pressing issue of integration and the preparation that needs to take place for such people to be part of mainstream school. It was reported that parents worried and struggled when dealing with school administration and teachers. Government should aim at increased awareness on ASD to the general public to reduce stigma.

161 **207.161** Prolonged Analysis of ASD Assessment Methodologies Utilizing the ADDM Dataset

ABSTRACT WITHDRAWN

Background: Appropriately identifying ASD can be challenging for practitioners. Differences in training, experience, and cultural/linguistic responsiveness can contribute to delayed or misidentification of ASD (AAP, 2016). Disparities in ASD identification by gender, socioeconomic status and race/ethnicity exist (Mandell et al., 2007). These disparities can significantly impact the educational, social and vocational outcomes for children with ASD. Limited research has been conducted investigating trends in ASD assessment practices over time, and how these practices relate to ASD identification trends by population.

Objectives: This analysis will investigate ASD assessment practices (e.g. types of ASD specific assessments, IQ tests, and adaptive measures) over time (2000 to present). The study will describe what types of assessments providers (medical, educational; as well as by specialty, psychologist, developmental pediatrician, etc.) utilize. The focus of this project will be to investigate changes in ASD assessment practices and whether they vary by provider, source type (education vs. health), and ADDM site.

Methods: Data acquisition has been proposed and approved by the CDC ADDM PI. The data is currently being processed and will be delivered to the lead author by January 15th, 2019. Following the acquisition of the dataset, the authors will determine the appropriate analyses given sample sizes. It is predicted that some analyses will need to be conducted using basic frequencies as the usage of certain assessments or numbers in populations may be limited. However, for more robust analyses the authors intend on utilizing multiple regression methodologies. Additional comparisons will be conducted to explore, e.g., 1) score profiles in relation to diagnostic/eligibility statements and ADDM case status, including the level of confidence ADDM clinician reviewers have in confirming case status; 2) patterns over time (2000-2014) in the use of assessment instruments for children at different ages, and the age at which children are diagnosed with ASD or other coexisting conditions; and 3) variation in testing practices in relation to children's sex, race/ethnicity, and socioeconomic status. Analyses will be limited to children in the "8-year-old" cohorts.

Results: This project will explore changes over time in the assortment of instruments used to diagnose ASD. Special attention will be given to the types and specialties of providers evaluating children with ASD, the frequency and variety of assessment tools utilized over time, the settings in which these instruments are used (education vs. health), and differences in practices among ADDM Network sites. Additional analyses will focus on differences in these assessment practices by child's age at the time of assessment, sex, race/ethnicity, presence/age of ASD diagnosis, coexisting diagnoses, and socioeconomic status.

Conclusions: ADDM data provide an ideal source of information to explore long-term changes in formal assessment practices among providers conducting diagnostic evaluation of children with ASD. These instruments are useful for diagnosing conditions such as ASD and intellectual disability (ID), to determine eligibility for services, and to inform strategies for service delivery. Changes in assessment practices may be related to trends in early identification, racial/ethnic health disparities, and socioeconomic factors.

162 **207.162** Quantifying Convergent Validity between Parent-Reported Developmental Concerns and Eye-Tracking-Based Measures of Social Visual Engagement

***A. I. Mendez**, T. A. Ponzo, A. Klin, C. Klaiman, S. Shultz and W. Jones, Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Parent-report plays a crucial role in the diagnostic landscape for autism spectrum disorder (ASD). Caregivers have the most in-depth experience of their children's development — offering information that might not be easily obtained within shorter-duration clinician-based assessments. Here, we investigate the association between performance-based, objective measures of a child's behavior, collected via eye-tracking, and parent-reported concerns on one of the most widely-used developmental screeners, the *Ages & Stages Questionnaire - 3rd Edition* (ASQ). We investigate whether parent's concerns are associated with a child's social visual engagement when viewing scenes of peer social interaction. Social visual engagement is a central means through which children define the course of their own developmental trajectories (Constantino et al., 2017): by engaging with certain aspects of their social environment, children gather unique information that alters their learning. In ASD, variation in social visual engagement is strongly associated with levels of clinician-measured social-communicative competence.
Objectives: To investigate the relationship between parent-reported developmental concerns and performance-based, objective measures of children's social visual engagement via eye-tracking in a large, heterogeneous, clinically-referred sample.

Methods: Parent-reported developmental concerns and eye-tracking data were collected from N=146 consecutive referrals (M_{age}=28.23 months, *SD*=6.89) to a community-based clinic. Children were referred because of general or ASD-specific developmental concerns. All children received a gold-standard diagnostic evaluation, including the *ADOS-2*, developmental history, and developmental functioning measures (ASD n=115, non-ASD developmental delays n=14, no clinically-verified delays n=17). Parent-reported developmental concerns were collected through the ASQ. Eye-tracking data were collected while toddlers watched video scenes of children in daycare settings and were quantified by measuring percentage of

visual fixation to faces and objects. Spearman correlation was used to test for associations between parent-reported concern and visual fixation to regions-of-interest.

Results: The data show significant associations between measures of social visual engagement and parents' concerns about their children's social-emotional and communication development, with increased attention to faces predicting fewer concerns (r=0.451, p<0.001 and r=0.330, p<0.001, respectively; see Figure 1) and increased attention to objects predicting greater concerns (r=-0.452, p<0.001 and r=-0.266, p=0.003, respectively; see Figure 1). Specifically, fixation on faces was significantly associated with parents' concerns about whether their child points, follows directions, plays pretend, plays with dolls, and talks like other children (all p<0.05). These associations appear specific to social-emotional and communication concerns, rather than to general developmental concerns, as fixation on faces was unrelated to parental concern about their child's ability to walk, jump, use stairs, turn doorknobs, or copy a line (all p>0.05).

Conclusions: Results indicate significant moderate convergent validity between eye-tracking-based measures of social visual engagement and parent-reported developmental concerns — consistent with prior research measuring the extent to which measures of social visual engagement are associated with clinician-administered assessments (Jones & Klin, 2013; Jones, Carr, Klin, 2008). Follow-up work will replicate the current results in an independent sample (N=105) and will test the extent to which the relationships between measures can be used to help clarify a challenge in the use of parent-report measures: biases that can manifest as inconsistently reported concerns.

163 **207.163** Racial and Ethnic Differences in Diagnosis and Service Use

L. M. Herbert[1], *M. N. Hale*[1], *G. David*[2], *N. Decius*[2], *D. Correa*[2], *M. Alessandri*[1] *and A. Gutierrez*[3], *(1)University of Miami, Coral Gables, FL, (2)Center for Autism and Related Disabilities, University of Miami, Coral Gables, FL, (3)University of Miami, Miami, FL*

Background: Prior research suggests racial and ethnic disparities in age of diagnosis and therapeutic/educational service use for individuals with autism spectrum disorder (ASD). Specifically, individuals from minority populations are commonly reported as being diagnosed later and receiving fewer services, relative to those from a non-minority group. Additional research is needed to better understand and address differences. Objectives: The purpose of this study is to examine differences in age of diagnosis and therapeutic service use for an ethnically diverse sample of individuals diagnosed with ASD.

Methods: Participants represented a subset of individuals who had previously registered with the SPARK (Simons Foundation Powering Autism Research for Knowledge) study. SPARK is an ongoing, nationwide autism genetic study funded by the Simons Foundation. SPARK participants are asked to provide a genetic sample and answer questions related to developmental/clinical history and symptom presentation. The University of Miami Center for Autism and Related Disabilities (UM-NSU CARD) serves as an affiliated clinical partner site, tasked with recruiting individuals into the SPARK study. For the current study, data from SPARK registrants who selected UM-NSU CARD as their affiliated site and who had completed a questionnaire related to background history were included. The sample consisted of 189 children and dependent adults with ASD (m=8 years (range 1-33 years), and included 58 (31%) Caucasians, 88 (47%) Hispanics, 14 (7%) African Americans & 29 (15%) from Mixed/Other race. Group comparisons of various diagnostic and service use variables were statistically evaluated.

Results: In this sample, there were no mean differences in age of diagnosis or onset of first concern based on racial/ethnic classification. Regarding education and service use, Caucasians had significantly higher use of psycho-pharmaceutical treatments; whereas African Americans were more likely to have repeated a grade in school. No other significant differences were identified in terms of school placement, school services, and other therapeutic interventions.

Conclusions: ASD is known to impact individuals across various racial and ethnic groups, and the clinical prognosis is impacted by access to early and high-quality interventions. Therefore, it is important to continue to examine the differences between racial and ethnic groups, in order to develop individual and community-based strategies to ameliorate such differences. In this sample, minority and non-minority groups received ASD diagnoses at comparable ages. While contrary to prior research, this finding may represent improvements in diagnosis across racial/ethnic groups. Furthermore, the University of Miami is located in an urban and ethnically-diverse area, whereby diagnostic trends may differ from those found in alternative locations. Despite comparable diagnostic ages, identified differences in treatments are clinically and educationally relevant. Future research may want to explore cultural differences in the perceptions and knowledge about psycho-pharmaceutical treatments. Furthermore, educational settings should continue to focus on efforts on addressing disparate educational practices for African American students.

164 **207.164** Screening Profile on M-CHAT(-R/F) for Toddlers Who Screened Positive for ASD and Received "No Diagnosis"

J. Chen, *M. Barton and D. A. Fein, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Previous findings indicate that children who fail an autism screener, the Modified Checklist for Autism in Toddlers with Follow-Up (M-CHAT/F) and its revision (M-CHAT-R/F) are highly likely to have significant developmental concerns. 97.7% (Chlebowski, Robins, Barton, & Fein, 2013) and 94.6% (Robins et al., 2014), respectively of screen-positive cases were diagnosed with ASD or other developmental delay or concern following comprehensive evaluations. Research has investigated which items of the M-CHAT(-R/F) best discriminate toddlers with and without ASD (Kamio et al., 2015; Robins et al., 2010). However, we have yet to specifically characterize a group of "No Diagnosis" children, or those who screen positive for risk for autism, but present with sub-clinical developmental concerns at evaluation.
Objectives: To compare items failed on the M-CHAT(-R/F) of children with "No Diagnosis" (ND) with typically developing children (TD; i.e., children who screened positive on the screener, but were within normal limits on all areas of development) and children diagnosed with ASD, global developmental delay (DD), and developmental language delay (DLD).

Methods: 169 toddlers (mean age at evaluation = 23.7 months, range: 16-41 months) who screened positive on the M-CHAT(-R/F) completed a diagnostic and developmental evaluation. 28 TD children, 39 children with ASD, 33 with DD, and 27 with DLD were matched on sex, age, and race/ethnicity to 42 children with ND. Total items failed on the M-CHAT(-R/F) was regressed onto diagnostic group in separate comparisons between ND and each other group. For each M-CHAT(-R/F) item, Fisher's Exact Tests compared the proportion of children in the ND group who failed the item to that in each other group. Data from M-CHAT items were combined with data from its corresponding M-CHAT-R/F item, with data from three items from the M-CHAT (i.e., peek-a-boo, playing with toys, and wandering without purpose) excluded. Due to the exploratory nature of these analyses, alpha levels were not corrected.

Results: Groups did not differ significantly on level of maternal education. The ND group had significantly fewer average total M-CHAT(-R/F) items failed compared to the ASD group (p=.001), but did not differ from the TD (p=.076), DD (p=.144), or DLD (p=.958) groups. Results from item-level analyses are presented in Table 1, and graphically represented in Figure 1 (attached).

Conclusions: At the first stage of autism screening, toddlers with sub-clinical developmental delays are distinguishable from toddlers with ASD but not other diagnostic groups, highlighting the role of the M-CHAT(-R/F) as an autism-specific screener. Items about social communication (e.g., response to name and language, response to and initiation of pointing) and play (e.g., pretend play, imitation) best distinguish ASD from ND, relative to other items (e.g., unusual motor activity). A subset of the same items also distinguish ND from DD. At screening, children with subclinical presentations are indistinguishable from children who have a DLD. Furthermore, the ND group is highly similar to the TD group at screening, other than being more likely to have poor language comprehension. These findings underline the importance of conducting further diagnostic evaluation for children who fail screening.

165 **207.165** Self-Diagnosis in Adults with Presumptive Autism Spectrum Disorder

N. Brondino[1], *L. Fusar-Poli*[2], *U. Provenzani*[1], *M. Rocchetti*[1], *S. Damiani*[1], *S. Lombardi*[1] *and P. Politi*[1], *(1)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy, (2)Department of Clinical and Experimental Medicine, Psychiatric Unit, University of Catania, Catania, Italy*

Background: as the prevalence of autism spectrum disorder (ASD) is constantly rising, an increasing number of adults with ASD is expected. Delayed diagnosis is quite common in subjects without cognitive impairment: these adults may be capable of functioning independently, but they frequently have to face challenges in everyday life (i.e. job, interpersonal relationship) which could lead to significant psychiatric comorbidities (i.e. depression), determining a reduction in the quality of life. Diagnosing ASD in adulthood is a challenge for the clinicians and only few specialized centers are available. Therefore, adults with presumptive autistic traits often rely on self-diagnosis, using the internet.
Objectives: the aim of the present study is to study the characteristics of self-diagnosed individuals who subsequently obtained a formal ASD diagnosis.

Methods:: 89 subjects who self-diagnosed themselves with ASD were evaluated by means of clinical interview for DSM 5 and standardized tests (ADOS 2 module 4, ADI-R if caregivers were available, cognitive tests). Sociodemographic and clinical characteristics were obtained for each subject.

Results: among self-diagnosed subjects only the 58.4% (n=52) obtained a formal diagnosis of ASD. These subjects showed low severity of symptoms according to DSM 5 (level 1: 57.7%; level 2: 40.4%), were more frequently males (71.2%), unemployed (52.9%) and single (90.4%). Nearly half of self-diagnosed subjects with a confirmed ASD had received at least one previous psychiatric diagnosis other than ASD (47.1%). Only 28.8% were on psychotropic medications. In stepwise logistic regression analysis, presence of a confirmed diagnosis in self-diagnosed subjects was significantly predicted only by age at evaluation (B=-0,086, SE=0,023, p<0.001).

Conclusions: There is an increase in ASD self-diagnosis in adulthood. This phenomenon may be link to increase knowledge and popularity of ASD in the media and may eventually lead to an increased request of formal diagnosis. However, ASD symptoms in adult not previously diagnosed may be subtler and covert, thus requiring trained clinicians.

166 **207.166** Self-Report and Parent-Report Reveal Similar Patterns of Executive Function Problems in Autistic Adolescents

R. Clinton[1], *C. Jeppsen*[1], *G. L. Wallace*[2], *A. C. Armour*[1], *A. Verbalis*[1] *and L. Kenworthy*[1], *(1)Children's National Health System, Washington, DC, (2)The George Washington University, Washington, DC*

Background: Parents of autistic individuals[a] consistently report global executive functioning (EF) problems in their children, with the greatest problems occurring in flexibility and meta-cognition (Granader et al., 2014; Wallace et al., 2016; White et al., 2017). Unlike parent report of EF, self-report allows autistic individuals to offer insight into their own experiences. As suggested by prior research, self-report provides the opportunity to obtain a more accurate understanding of an individual's behavior (Verhulst & van der Ende, 1992; Robins, Fraley & Krueger, 2009). To date, however, research has only investigated self-report of EF in older autistic adults (Davids et al., 2016).
Objectives: To investigate whether autistic youth self report EF problems and if their self-reported profile yields a similar pattern of EF problems to that reported about them by their parents.

Methods: Archival data on the Behavior Rating Inventory of Executive Function (BRIEF) self-report from 134 autistic youth (101 male, ages 11.0–18.75 years, FSIQ≥71) and BRIEF informant report from parents (n=134) were evaluated. One-sample T-tests were utilized to determine if the self-ratings represented statistically significant elevations in EF problems compared to the expected T-score mean of 50. The parent- and self-report versions of the BRIEF have the same three domains in the Behavior Regulation Index (BRI), but only share four of the same domains in the Metacognition Index (MCI); see Figure 2. Therefore we ran two general linear model (GLM) repeated measures ANOVAs to a) examine the self-report BRIEF profile in autistic youth and b) compare subscale score patterns from the BRIEF self- and parent-report in the same autistic youth.

Results: Autistic youth reported significantly elevated EF problems compared to the expected mean for all BRIEF domains (*p*'s<.005) except for the Inhibit domain (*ns*); see Figure 1. A GLM repeated measures ANOVA showed a main effect of BRIEF domain score for autistic youth, $F(5.39, 242.26)=2.98$, $p<.01$). A second GLM repeated measures ANOVA showed a main effect of BRIEF domain score, $F(4.84, 509.22)=5.35$, $p<.001$, and of rater, $F(4.84, 879.57)=9.24$, $p<.001$, as well as an interaction between rater and domain score, $F(1,265)=80.03$, $p<.001$, indicating that parents report higher levels of problems than their children report; see Figure 2. Post-hoc paired-sample T-tests show peak problems in the BRI Shift subdomain for both parent, ($t=71.22$, $p<.005$), and self-report, ($t=57.84$, $p<.05$), across all domains except for self-report of MCI Task Completion (*ns*) and parent-report of MCI Working Memory (*ns*).

Conclusions: These findings suggest that autistic youth self report a profile of EF problems to a greater degree than the normative BRIEF sample. Although they report less severe problems than their parents report about them, autistic youth identify a pattern of difficulties that emphasizes flexibility problems and metacognitive deficits, as do their parents. These results suggest that autistic youth recognize and can identify their own EF challenges. Therefore, assessing the lived experiences of autistic youth is critically important to clinical and research endeavors involving autistic individuals.

[a] Identity-first language rather than person-first language is used frequently in this abstract, consistent with practice among autistic self-advocates.

167 **207.167** Self-Report of Physical Health, Sexual Well-Being, and Alcohol Use in Adults with Autism Spectrum Disorder (ASD)

A. Pearl[1], *J. H. Essayli*[2], *S. L. Calhoun*[3], *J. Fernandez-Mendoza*[3] *and M. Murray*[1], *(1)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (2)Pediatrics, Penn State College of Medicine, Hershey, PA, (3)Psychiatry, Penn State College of Medicine, Hershey, PA*

Background: There is increasing evidence that individuals with ASD experience higher rates of physical health problems (e.g., gastrointestinal disorders, sleep disturbances, obesity) as compared to the general population. However, previous researcher has also found that some conditions are less commonly diagnosed in adults with ASD (e.g., alcohol abuse/dependence). To the author's knowledge, little is known about adults self-report of their own physical health, sexual functioning, and alcohol use.
Objectives: To explore profiles of self-reported physical health, sexual interest and satisfaction, as well as alcohol use in adults with ASD.

Methods: Data was collected from adults with ASD who were enrolled in state-funded programs in Pennsylvania. Participants completed a battery of self-reported questionnaires from the Patient-Reported Outcomes Measurement Information Systems (PROMIS), which measured physical health, sleep disturbance, impairment, fatigue, sexual interest and satisfaction. Additionally, current alcohol use in the past 30 days and BMI were included. Our sample of 55 adults with ASD is predominantly male (81.3%), White (89.1%) with a mean education level of 12.89 ± 1.91 years, and a mean age of 31.17 ± 7.64 years. 51% reported currently living with their parents. Mean SRS-2 Total T-Score was 61.44 ± 8.31.

Results: 27% of BMIs fell in the overweight range while 60% fell in the obese range (30.86 ± 5.35); this is significantly higher than the BMI for average Americans (25.55; $p = 0.01$). 16% of participants reported physical health problems and sleep impairment in the borderline range. 8% of participants reported borderline fatigue, as well as sleep disturbance. 4% reported clinical symptoms of fatigue. 2% reported clinical symptoms in sleep impairment/disturbance. 43% of participants reported no interest in sexual activity; however, 50% of participants reported that they are not satisfied with their sex life regardless of their reported level of interest in sexual activity. 16% of participants reported having drank at least one drink of an alcoholic beverage in the last 30 days compared to the American average of 56%. Physical health was correlated with being unemployed ($r = -.29$, $p < .05$), SRS-2 Total Score ($r = .33$, $p < .05$), sexual interest ($r = -.42$, $p < .05$), fatigue ($r = .68$, $p < .01$), sleep disturbance ($r = .29$, $p < .05$), and sleep impairment ($r = .42$, $p < .01$). Sleep impairment was associated with living with parents ($r = -.35$, $p < .01$). SRS-2 Total T-Score was correlated with greater sexual interest ($r = 0.36$, $p < .05$). Finally, drinking alcohol was associated with higher sexual satisfaction ($r = 0.58$, $p < .05$).

Conclusions: Self-report of physical health problems, sexual satisfaction and interest, and alcohol use in adults with ASD using PROMIS measures parallel findings from larger studies of children with caregiver self-report or big-data research, including higher rates of obesity in adults with ASD. Future research with larger, more representative samples of adults with ASD is necessary to clarify the degree to which physical health problems, sexual interest and satisfaction, as well as alcohol use in adults with ASD impact each other.

168 **207.168** Sensitivity and Specificity of the Social Communication Questionnaire in a Diverse Clinical Sample

B. Rennie[1], *C. Burnette*[2] *and O. Myers*[3], *(1)University of New Mexico, Center for Development and Disability, Albuquerque, NM, (2)Pediatrics, Center for Development and Disability, University of New Mexico, Albuquerque, NM, (3)Family and Community Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM*

Background: Screening questionnaires precede a full evaluation to determine the likelihood of an Autism Spectrum Disorder (ASD) diagnosis. They are inexpensive, relatively easy to administer and are used by a variety of professionals across general (e.g., pediatrician office) and clinically referred (e.g., early intervention agency, diagnostic clinics) settings. When used in pediatric populations, developmental screening questionnaires

are most often completed by parents and are intended to gather information about emerging developmental abnormalities that may prompt further assessment by a specialist. Ideally, the results of these questionnaires can inform clinical triage and evaluation processes. However, a review of several ASD-specific screening questionnaires suggested that they often show low sensitivity and are in need of higher levels of scientific scrutiny (Norris & Lecavalier, 2010). The *Social Communication Questionnaire* is a 40-item screening measure completed by parents for identifying symptomatology associated with ASD *(*SCQ*;* Rutter et al., 2003*)*. Despite its popularity, there is limited research that examines how the SCQ functions in diverse clinical populations (Baio, 2018).

Objectives: This study provides a unique opportunity to understand better the sensitivity and specificity of the SCQ within a large, diverse clinical sample in New Mexico with Hispanic and Non-Hispanic populations.

Methods: We compiled a database using information from clinical evaluations completed at the University of New Mexico Center for Development and Disability. The Autism Spectrum Evaluation Clinic completes comprehensive diagnostic evaluations of children who are referred for concerns related to ASD. Our preliminary sample included children between ages 2-18. We conducted sensitivity and specificity analyses across age and ethnic groups using the SCQ published cut score of 15. Fisher exact tests and logistic regression with Firth's penalized likelihood were used to assess heterogeneity in sensitivity and specificity. Non-parametric tests were used to compare continuous variables.

Results: Our preliminary sample included 218 children with 126 (58%) receiving a diagnosis of ASD, 167 (77%) being males and 55% self-identified as Hispanic. ASD was diagnosed for 56% of Hispanic and 60% of Non-Hispanic children. Sensitivity was 0.86 (95% CI = 0.73, 0.95) for the No Language group, 0.50 (0.34, 0.66) for age 2-4 years, and 0.76 (0.61, 0.87) for age 5-18 years. Specificity was 0.40 (0.16, 0.68) for the No Language group, 0.57 (0.34, 0.78) for age 2-4 years, and 0.28 (0.17, 0.41) for age 5-18 years. Overall, sensitivity was not different for Hispanic and Non-Hispanic (P = 0.162) groups, but specificity was lower for age 5-18 Hispanic than Non-Hispanic groups age 5-18 years (P=0.023).

Conclusions: Results of this study indicate that sensitivity and specificity of both Hispanic and Non-Hispanic groups vary greatly across age groups. Further analyses are needed to determine additional factors (e.g., cognitive ability, lower cutoff score) that impact sensitivity and specificity in this clinical sample that can be used to maximize the functionality of the SCQ to inform better clinical referral and triage decisions in diverse populations.

169 **207.169** Sex Differences in CARS Scores for Toddlers with Autism Spectrum Disorders

K. Fobian[1], *K. Coulter*[2], *D. L. Robins*[3], *M. Barton*[2] *and D. A. Fein*[2], *(1)University of Connecticut, Storrs, CT, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background:

Autism Spectrum Disorder (ASD) is four times more prevalent in boys than girls (CDC 2018). Girls may display a different symptom profile than boys, which may impact diagnosis rates; however, previous studies report conflicting results on sex differences in ASD symptoms. Some studies report no significant differences between sexes (Carter et al., 2007), while others report more stereotyped behavior in boys (Hartley & Sikora, 2009) and greater social communication impairments in girls (Lawson et al., 2018). Studies examining sex differences in total and item level scores on ASD diagnostic measures present similar contradictions (Beggiato et al., 2017; Pilowsky et al., 1998 Rynkeiwicz et al., 2016; Tillman et al., 2018). Given these inconsistent results and that participants in most of these studies are older children and adults, more research is needed to determine sex differences in ASD symptoms among toddlers and how these differences impact the utility of diagnostic tools.

Objectives:

To investigate sex differences in scores on the Childhood Autism Rating Scale (CARS) to examine the utility of the CARS for toddler-aged boys and girls. Specifically, based on prior literature, to test the hypothesis that male and female toddlers receive similar scores on overall severity, emotional reactivity, and stereotyped behaviors, but female toddlers exhibit more impairment in social communication.

Methods:

Participants for this study were part of a multi-site early detection study (Robins et al. 2014). Parents completed the Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R) at their child's 18- or 24-month checkup and were offered a diagnostic evaluation if the child screened at risk after follow-up. This sample includes 323 participants who completed the evaluation between the ages of 17 and 27 months and met ICD-10 criteria for Childhood or Atypical Autism. There were no significant differences between sexes in age ($t(321)=0.308$, $p>.05$) or cognitive ability ($t(321)=-0.671$, $p>.05$). The CARS is a 15-item observation-based rating scale that yields a total score reflecting ASD symptom severity (Schopler et al., 1980). CARS items were divided into three factors (social communication, emotional reactivity, and stereotyped behaviors and sensory sensitivities) based on a factor analysis completed by Moulton et al. (2016). Factor scores were calculated by averaging the scores of all items included in a factor.

Results:

No significant differences were found between boys and girls on total severity scores, factor scores, or individual item scores (Table 2).

Conclusions:

Results support the hypothesis that male and female toddlers score similarly on overall severity, emotional reactivity, and stereotyped behaviors. Results do not support the assertion that female toddlers score higher on items assessing social communication. This suggests that the CARS is a valid diagnostic measure for both male and female toddlers and supports previous findings that show little to no sex differences in ASD core symptoms (Carter et al., 2007). Future studies should continue to compare the symptoms reported for male and female toddlers with ASD to determine any sex differences in symptom profiles and determine the utility of diagnostic measures across sexes.

170 **207.170** Sex Differences in Symptom Profiles in a Preschool Sample of Hispanic Children with ASD

J. Durocher[1], *M. N. Hale*[1], *S. Cardona*[2], *G. Victoria*[3], *E. M. Davis*[3], *A. Beaumont*[1] *and M. Parladé*[1], *(1)University of Miami, Coral Gables, FL, (2)Psychology, University of Miami, Coral Gables, FL, (3)Mailman Center for Child Development, University of Miami, Miami, FL*

Background: Females with ASD may show phenotypic differences in behavioral and/or cognitive patterns[1-3], which may vary by age[4-5]. Female toddlers with ASD may demonstrate more severe social communication impairments and less severe restricted and stereotyped behaviors, although these finding differ across studies[6-8]. However, the majority of studies have been conducted primarily with white families, although ASD

diagnosis and symptom presentation also varies according to race/ethnicity, with minority children exhibiting later diagnosis, lower cognitive and language scores and more severe ASD symptoms[9-11]. The extent to which gender differences exist *within* minority groups has not been adequately examined.

Objectives: To evaluate sex/gender differences in symptom presentation within a minority sample of Hispanic preschool-age children referred for diagnostic evaluations.

Methods: The overall sample is comprised of 153 children between the ages of 2 and 5 who were evaluated at an University-based specialty diagnostic clinic as part of a services grant for children suspected of having an autism spectrum disorder. Children at risk for ASD based on screening results were referred directly through local Part C and Child Find services and were either (1) Medicaid eligible or lacking private insurance (2) Head Start or Early Head Start eligible or (3) zoned for a Title 1 schools. Current analyses include only those children who received diagnoses of ASD and who also identified as being of Hispanic descent (n=89, 58% of initial sample), resulting in 43 females (48.3%) and 46 males (51.7%), with a mean age of 45.94 months (SD=9.71) and nonverbal IQ of 72.18 (SD =24.59).

Results: Females were significantly younger at referral (M_F=43.23 vs M_M=48.43 months), *t*= - 2.583 (87), *p*=.011. Age and nonverbal IQ (NVIQ) were significantly correlated, but only for males (*r* =.337, *p*=.022). Patterns of correlations between age, nonverbal IQ and outcome measures differed for females vs. males (see Tables 1-3). Due to this, MANOVAs and MANCOVAs were conducted to test for differences between females and males across the various symptom measures, with age as a fixed factor; age and/or NVIQ as entered covariates, depending on the pattern of correlations observed.

No significant sex differences in NVIQ, receptive or expressive language, or parent report of autism symptoms were found. However, females had lower communication (Battelle Developmental Inventory-2) scores ((M_F=58.83, SD=6.046 vs.M_M=66.38, SD=18.464), *F*(1,66)= 4.477, *p*=.038) and higher ADOS Social Affect severity scores ((M_F=6.70, SD=2.356 vs. M_M=5.00, SD=2.996), *F*(1,86)= 8.189, *p*=.005), after controlling for NVIQ. Females were also rated as more severe with respect to BASC attention problems, ((M_F=67.49; SD=10.018 vs. M_M=61.11; SD=9.778), *F*(1,87)=9.240, p=.003)) and atypicality ((M_F=67.12; SD=16.776 vs. M_M=60.41; SD=13.864), *F*(1,87)=4.247, p=.042). Finally, females were also more likely to have a comorbid diagnosis of Pica, χ^2(1,N=89)= 5.667, p=.017.

Conclusions: Male and female Hispanic children are more similar than different on the majority of measures. However, some differences were found with respect to age of referral, clinician ratings of ASD symptom severity, communication abilities, parent reported behavioral symptoms, and patterns of comorbidity. Implications of these findings for the diagnostic and treatment process will be discussed.

171 **207.171** Sex Differences in the Sensitivity, Specificity, and Diagnostic Cutoff of the Childhood Autism Spectrum Test (CAST) in Israel

S. Israel Yaacov[1,2]*, N. Shachar*[1] *and O. Golan*[1]*, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel*

Background: The past decade has seen a shift in the understanding of the different clinical picture of Autism Spectrum Disorder (ASD) in females. Due to various factors, such as test sensitivity and female camouflaging effect (Lai et al., 2011), females on the more functioning end of the autism spectrum have often been missed out (Loomes et al., 2017). It is therefore important to examine the sensitivity of ASD screening instruments separately for boys and girls. The the Childhood Autism Spectrum Test (CAST; Scott et al., 2002) is an ASD screening instrument that has been widely used in the UK (e.g. Allison et al., 2007) as well as cross-culturally (Morales et al, 2017; Sun et al., 2014; Vulchanova, et al., 2016). However, the instrument's cutoff has not been tested separately for boys and girls.

Objectives: The current study aimed to test the sensitivity, specificity and diagnostic cutoff of the CAST in Israel by comparing a clinical sample of boys and girls to a typically developing sample.

Methods: Participants were 295 children, aged 6-12. The clinical group included 101 children: 79 boys (age: 9.08, S.D.=1.97) and 22 girls (M=9.36, S.D.=1.89), recruited through a tertiary ASD clinic, who were clinically diagnosed, based on the ADI-R and the ADOS-2. They were compared to 194 typically developing children: 102 boys (M=8.86, S.D.=1.98) and 92 girls (M=8.88, S.D.=1.94), recruited through internet forums and reported to have no neuropsychiatric diagnoses. Participants' parents filled out the Hebrew translation of the CAST. The clinical cutoff, sensitivity and specificity of the CAST total score were calculated separately for boys and for girls. A calculation of the cutoff for the entire sample was conducted after partialling out some of the typically developing girls sample, to ensure m:f proportion is similar in the clinical and the typical groups.

Results: The separate analysis for boys and girls showed that the optimal cutoff score was 13, with a sensitivity of 0.82 and a specificity of 0.86 (AUR=.91, S.E.=.02), while for girls the cutoff score was 8, with a sensitivity of 0.91 and a specificity of 0.89 (AUR=.97, S.E.=.01). The joint analysis over and above sex, yielded an optimal cutoff score of 12, with a sensitivity of 0.83 and a specificity of 0.84 (AUR=.92, S.E.=.02).

Conclusions: Our examination of the CAST demonstrates the need for separate cutoffs for boys and girls. By employing a joint cutoff, there is a risk of missing out girls whose presentation of symptoms may be more subtle, or camouflaged. Interestingly, despite the lower cutoff for girls, it still allowed for better discrimination between ASD and TD, than the cutoff for boys. It is important to note that our sample of girls with ASD was relatively modest. Further studies should examine different cutoffs for girls and boys on the CAST, as done for other screeners, such as the SRS-2 (Constantino & Gruber, 2012).

172 **207.172** Signs of Autism Found on Chart Review of Screen-Negative Children with Autism

K. Campbell[1]*, T. P. Gabrielsen*[2]*, A. L. Stuart*[3] *and P. Carbone*[1]*, (1)University of Utah, Salt Lake City, UT, (2)Counseling & Special Education, Brigham Young University, Provo, UT, (3)General Pediatrics, University of Utah, Salt Lake City, UT*

Background: Autism screening is widely employed to help pediatricians identify children at risk for autism, refer for prompt diagnostic evaluation, and start crucial early intervention. However, the mean age of diagnosis nationally is 52 months, approximately 2 years after autism screening. Screening instruments have estimated high sensitivity, but do miss some cases and can be falsely reassuring. Children who screen negative but go on to receive an autism diagnosis may have early signs of autism in routine medical and developmental history taken at well visits.

Objectives: To search medical records of children with autism who had false negative results on autism screening for behaviors or concerns associated with autism present prior to diagnosis in order to identify areas of development that should be added to the surveillance and screening process for autism.

Methods: Charts were reviewed within a large healthcare system for children who were 16-30 months old and screened for autism in 2013-2016. A

cohort was identified who were screened with the Modified Checklist for Autism in Toddlers (M-CHAT) or the revised version (M-CHAT-R), and who had a later diagnosis of autism in their medical record based on the presence of an ICD code consistent with ASD. Charts of screen-negative children were first manually reviewed by autism experts to confirm autism diagnoses. Among those children with confirmed autism, provider notes were manually searched for documentation of early signs of autism and co-morbidities often associated with autism, and frequencies of these findings were calculated.

Results: 161 children with autism screened by the M-CHAT from 2013-2016 were identified. Of these, 99 (61%) screened positive on the M-CHAT and 62 (39%) children with confirmed autism screened negative. Among screen-negative cases, 66% had impairments noted in social communication, 60% had severe dysregulation of feeding or sleep or both, 48% had repetitive or restrictive play, 60% had abnormal sensory seeking or avoiding behaviors, 18% had a sibling with autism, 71% had a parental concern for autism, and in 61% the physician recorded a concern for autism. Overall, 79% of screen-negative children with autism had record of a parent or physician concern within the areas of social communication or repetitive/restricted play.

Conclusions: Most screen-negative children with autism had early markers of atypical development apparent in chart review prior to their autism diagnosis. A larger than expected proportion of children with autism had a negative screen, given previous studies of the M-CHAT showing high sensitivity. Notably, for most children studied, either the parent or the physician themselves reported a concern for autism. Despite signs of autism, a negative screen may be falsely reassuring against an autism diagnosis. Clinical signs of autism should prompt referral for further evaluation, and should not be overruled by a negative autism screen. Continued improvement of the screening process and screening instruments for autism are needed to improve early identification of children with autism.

173 **207.173** Sociodemographic Predictors of M-CHAT Responses Among Children Who Screened Positive

M. Udhnani[1], *K. E. Wallis*[2], *A. Bennett*[3], *J. S. Miller*[4], *M. Augustyn*[5] *and E. Feinberg*[6], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Children's Hospital of Philadelphia, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Boston University School of Medicine, Boston, MA, (6)Boston University School of Public Health, Boston, MA*

Background: Children from minority and low-income backgrounds are likely to be diagnosed with autism spectrum disorder (ASD) at a later age (Mandell, Novak, & Zubritsky, 2005). The Modified Checklist for Autism in Toddlers, Revised, with Follow-up (M-CHAT R/F; Robins, Fein, & Barton, 2009), is a parent completed screening questionnaire. If universally administered, the M-CHAT R/F may help reduce racial and ethnic disparities in age of identification. However, among children who screen positive on the M-CHAT-R/F), little is known about whether sociodemographic factors further predict item-level responses or total M-CHAT-R/F scores.

Objectives: The current study aims to examine whether sociodemographic factors predict both item-level responses and total scores on the M-CHAT-R/F.

Methods: Participants are children aged 15-30 months who screened positive on the M-CHAT R/F at the baseline visit of a NIMH-funded multi-site comparative effectiveness trial (N=310; see Table 1). The population is largely low-income, majority-minority, with public insurance. Research assistants read parents the M-CHAT-R/F and demographic questionnaires at the time of enrollment. A priori hypotheses stated that parent and child sociodemographic factors would predict M-CHAT-R/F item-level responses. Multivariable logistic regression models included all sociodemographic factors (child race; ethnicity; sex; insurance; maternal education level; and – as a proximal marker for low income-- enrollment in Women, Infant, Child [WIC] nutritional program) simultaneously. Because the data were aggregated from a multi-site study, analyses controlled for clinical site of enrollment.

Results: Statistically significant results of multivariable logistic regression models are reported in Table 2. Total M-CHAT R/F score was not significantly associated with any sociodemographic factors. Child ethnicity and insurance type were not significantly associated with item-level responses. However, at the item level, parents were more likely to report wondering if their child was deaf (M-CHAT-R/F item 2) if the child's race was white rather than black or Asian. Across races, mothers who completed college were less likely to wonder if their child was deaf. Parents of females were more likely to report that their child attempts to copy what they do (M-CHAT-R/F item 15). Low income families (as measured by WIC enrollment) were less likely to agree that their child looks around to see what parents turn around for (M-CHAT-R/F item 16).

Conclusions: These findings suggest that sociodemographic variables may affect either early ASD presentation or parent perceptions. Future research should investigate further differences in cognitive and behavioral functioning as they pertain to sociodemographic variables as well as ways these variables may affect interpretation of M-CHAT-R/F items.

174 **207.174** Measurement of Challenging Behaviors and Child Engagement in Youth with Creatine Transporter Deficiency

J. S. Miller[1], ***M. Udhnani***[2], *S. Plate*[2] *and A. Thurm*[3], *(1)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)National Institute of Mental Health, Bethesda, MD*

Background: Challenging behaviors during standardized testing are prevalent among children with autism and intellectual disability (ID). Such challenging behaviors are a frequent focus of intervention, as they may decrease the child's ability to function independently and participate in the community. Standardized measurements of cognitive functioning generate scores that describe performance on developmental tasks relative to typically developing peers but fail to consider behaviors that may impact performance (e.g. disruptive behaviors, participant engagement). This is unfortunate, since a reduction in challenging behaviors may be one of the first outcomes of intervention, and a more proximal measure of improvement than standardized test scores. To date, no research has examined the specific profile of challenging behaviors in Creatine Transporter Deficiency (CTD), a rare genetic disorder associated with intellectual disability and a high risk of autism spectrum disorder.

Objectives: Using video samples of standardized assessments, the current study aims to quantify the amount of time the child is demonstrating challenging behaviors and the amount of time the child is appropriately engaged.

Methods: The sample consists of 20 male participants with CTD, each of whom have at least two time points of data collection (6 months apart). A review of qualitative interview data with parents of children with CTD and review of previously collected video recordings of standardized assessments informed the design of a behavioral coding scheme. Using a linguistic coding software, EUDICO Linguistic Annotator (ELAN, 2018), raters will utilize 10-minute video samples of the Mullen Scales of Early Learning (MSEL; Mullen, 1995) or the Wechsler Achievement Scale of

Intelligence (WASI; Wechsler & Hsiao-pin, 2011) to code for behavioral patterns exhibited in this population.

Results: Videos from 3 participants were coded from two time points each. 1) adult time spent attempting to engage the child; 2) presence of disruptive behaviors (crying/whining, inappropriately touching or grabbing objects, property destruction, aggression, and eloping); and 3) duration of child engagement (appropriate listening, waiting, or acting). Findings from the first three participants indicate that with an average duration of Demands Placed at approximately 8.9 minutes, the ratio of Disruptive to Engaged time during standardized testing ranged from [0:9.7 to 2.5:4.0] at Time 1 and [0:9.8 to 3.0: 2.9] at Time 2. Coding for the videos from the remaining 17 participants is underway and will be available for presentation.

Conclusions: Quantifying challenging behaviors that occur during cognitive testing may provide an important outcome measure that could be sensitive to intervention and more objective than parent or teacher report. If sensitive to intervention, duration of time spent in challenging behavior and duration of child engagement could be more proximal outcome measures than a change in standardized test scores.

175 **207.175** Student, Parent, and Teacher Perspectives of Self-Determination in High School Students with Autism Spectrum Disorder

B. Tomaszewski[1], *B. Kraemer*[2], *L. E. Smith DaWalt*[3], *K. Hume*[1], *J. R. Steinbrenner*[1], *L. J. Hall*[2] *and S. Odom*[1], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Special Education, San Diego State University, San Diego, CA, (3)University of Wisconsin-Madison Waisman Center, Madison, WI*

Background: Self-determination refers to an individual being a causal agent in their daily activities including the ability to express their own needs, interests, and wants to make choices and set goals. Self-determination is critical during adolescence and has been linked to positive educational outcomes in individuals with disabilities. Few studies have characterized the measurement of self-determination in adolescents with ASD.

Objectives: The purpose of the current study was to (1) examine the reliability and factor structure of the American Institutes for Research Self-Determination Scale (AIR-SDS; Wolman et al., 1994) student, parent, and teacher forms for high school students with ASD, and (2) examine student and family predictors of self-determination.

Methods: Participants were part of a larger RCT of a comprehensive treatment model for high school students with ASD. The current study utilizes data collected prior to the intervention. Participants included adolescents with ASD (N = 488, Mean Chronological Age = 16.1 years SD = 1.4 years), their parents, and teachers. Students, parents, and teachers completed the AIR-SDS. The AIR-SDS measures two broad self-determination components; a student's capacity, or their knowledge, abilities, and perceptions that enable them to be self-determined, and opportunities to use their knowledge and abilities at home and in the classroom. Parents completed the Family Empowerment Scale and the Zarit Burden Interview. Teachers completed the Social Responsiveness Scale as a measure of autism symptoms and the Vineland Adaptive Behavior Scales as a measure of adaptive behavior.

Results: The student-reported self-determination overall mean had small associations with parent-report (r= .11, p = .04) and teacher-report (r = .11, p = .04). Teacher and parent-reports were moderately correlated (r = .27, p < .001). Item analysis and confirmatory factor analysis were conducted for each version of the AIR-SDS. The internal consistency of the AIR-SDS was high across students (Cronbachs α = .92), parents (Cronbachs α = .91), and teachers (Cronbachs α = .96). The standardized factor loadings supported the hypothesized factor structure in addition to model fit statistics for the student report, RMSEA = .06 (90% CI [.03 , .10]), CFI = .98, TLI = .96, parent report, RMSEA = .07 (90%CI [.04 , .09]), CFI =. 97, TLI = .95, and teacher report, RMSEA = .06 (90% CI [.04. 09]), CFI = .99, TLI = .97. Greater adaptive behavior skills were significantly associated with increased student, parent, and teacher-reported capacity and opportunity. Decreased autism symptoms was a significant predictor of increased teacher-reported capacity. Increased family empowerment was associated with increased parent-reported capacity and opportunity. Decreased family burden was associated with increased parent-reported capacity and parent and teacher-reported opportunity.

Conclusions: The current study provides support for use of the AIR-SDS with high school students with ASD along with their parents, and teachers. Adaptive behavior was a significant predictor of self-determination across reporters highlighting the significance of adaptive behavior skills during high school. In addition to promoting adaptive behavior, supporting family empowerment and reducing family burden may help to increase self-determination in high school students with ASD.

176 **208.176** Augmenting mGluR5 Activity Ameliorates Behavior Deficits in a Transgenic Rat Model of Autism Spectrum Disorder

R. Mittal[1], *M. M. Perdomo*[1], *H. Marwede*[1], *E. J. Horesh*[2], *J. Mittal*[1] *and* ***A. A. Eshraghi***[3], *(1)University of Miami School of Medicine, Miami, FL, (2)University Of Miami School of Medicine, Miami, FL, (3)Otolaryngology and Neurological Surgery, University of Miami Miller School of Medicine, Miami, FL*

Background: Despite the high prevalence of autism spectrum disorder (ASD), there are currently no FDA approved medications for treating the core symptoms of this neurological disorder. There is an urgent need to develop new treatment modalities in pursuit of improving the quality of life of ASD individuals and their families. A number of genes implicated in the pathophysiology of ASD converge on the metabotropic glutamate receptor 5 (mGluR5) pathway. As a proof of this concept, pharmacological enhancement of mGlu5 receptors rescues behavioral deficits in *SHANK3* knockout (KO) mice. In addition, treatment of *Mecp2*-deficient mice with mGluR5 positive allosteric modulator (PAM), VU0462807, improves behavior defects. All these studies lay a strong foundation to explore the potential of augmenting mGluR5 activity as a potential treatment modality for ameliorating core symptoms of ASD. However, all the studies have been performed in mice that do not show complex social behavior especially during development. This is important since ASD is a developmental disorder, and modeling the impaired social behavior during development is critical in clinically relevant animal models of ASD. However, the efficacy of mGluR5 PAM in ameliorating ASD associated core symptoms has never been determined in a transgenic rat model.
Objectives: The aim of this study was to evaluate the efficacy of mGluR5 positive allosteric modulator (PAM) 3-Cyano-N-(1,3-diphenyl-1H-pyrazol-5-yl)benzamide (CDPPB) in ameliorating behavior and communication deficits in a well-established ASD transgenic rat model.

Methods: The social interaction profiles of WT and ASD rat model were evaluated on day 8 after treatment with CDPPB (5 mg/ kg) for seven days. Vehicle treated animals or untreated ASD rats as well as WT animals served as the control group.

Results: We observed that treatment of transgenic ASD rats with CDPPB improves social deficits compared to vehicle or untreated animals on day 8 post-administration. These results are in agreement with previous studies demonstrating the efficacy of mGluR5 agonists in ameliorating behavioral deficits in ASD mouse models.

Conclusions: The results of our study argue to explore the efficacy of mGluR5 agonists in developing novel therapeutic strategies for ameliorating core symptoms of ASD. The availability of new treatment modalities will help in improving quality of life of ASD individuals and their families.

177 **208.177** Polypharmacy and Medication Monitoring Among Children and Youth with ASD

K. J. Hewitt[1], *C. Ritter*[2] *and C. A. McMorris*[1], *(1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)School and Applied Child Psychology, University of Calgary, Calgary, AB, Canada*

Background: Pharmacotherapy is commonly used to treat individuals with autism spectrum disorder (ASD). Polypharmacy however—the use of two or more medications simultaneously (psychotropic or non-psychotropic)—remains a relatively underexplored area, and yet as many as 87% of children with ASD may be prescribed polypharmacy intervention (Wink et al. 2017). Despite this high prevalence, it is unknown if and how health practitioners are monitoring the use and associated side effects of multiple medications.
Objectives: A systematic literature review was conducted to establish polypharmacy trends among children and youth with ASD, identify specific factors associated with multiple medication use, and to determine if and how medication use, and commonly experienced side effects are monitored over time.

Methods: Five different electronic databases: PsycINFO, Medline, CINAHL, Embase, and Cochrane were used. A total of 16 studies encompassing over 300,000 children and youth with ASD were included after being evaluated for scientific strength using the Joanna Briggs Institute Prevalence Critical Appraisal Checklist (Joanna Briggs Institute, 2014).

Results: Overall, the majority of participants were male, 25 years of age or younger, and rates of polypharmacy varied from 9% to 87%. While rates of polypharmacy use were similar between males and females, medication type differed by sex. Whereas males were prescribed stimulants more often, females were regularly prescribed antidepressants or mood stabilizers. Factors commonly associated with higher rates of polypharmacy included psychiatric co-morbidities, self-injurious behavior, physical aggression, and age.

Conclusions: This systematic review highlights the considerable number of children and youths with ASD taking multiple psychotropic and non-psychotropic medications, and yet only one study addressed medication monitoring and the possible long-term effects of polypharmacy. Findings emphasize the importance of medication monitoring among children and youth with ASD receiving polypharmacy.

178 **208.178** The Utility of Omnibus Statistical Approaches in Go/No-Go Decision Making in a Phase 2 Study in Adolescents with Autism Spectrum Disorder: A Case Example

E. Anagnostou[1], ***J. P. Horrigan***[2] *and A. Yaroshinsky*[3], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Duke Autism and Brain Development Center, Durham, NC, (3)Vital Systems, Inc., Rolling Meadows, IL*

Background:
The informativeness of Phase 2 clinical trials in autism spectrum disorder (ASD) has been diminished by a lack of gold standard, syndrome-specific outcome measures that render clear, easy-to-interpret results. This shortcoming has undermined confident go/no-go decision-making when deciding whether a drug candidate is worthy of further clinical development, or not.

Objectives:

One potential remedy involves better statistical approaches that improve confidence in results analyses, especially when the size of the study is relatively small. In this example, two omnibus statistical approaches were applied to a recent set of ASD Phase 2 clinical trial results, to determine the likelihood of the pattern of affirming efficacy findings in the study being a reflection of false discovery (i.e. a false positive finding).

Methods:

The efficacy results were derived from a study involving AMO-02/tideglusib. This orally administered new chemical entity is a GSK-3β enzyme inhibitor with multiple converging lines of preclinical evidence that indicate that it may represent a potential therapeutic agent for individuals with ASDs.

In this study, 83 adolescents between 12 and 16 y.o. were blindly randomized 1:1 to placebo or AMO-02/tideglusib which was up-titrated from 400 mg to 1000 mg once-daily, weight-adjusted, during a 12-week active treatment period.

A step-wise omnibus approach was utilized, commencing with a concordant trend analysis that simultaneously considered mean results from 7 pre-specified outcome measures utilized in the study (including the ABC, VABS, RBS, OARS, and Parent Chief Complaint rating scales as well as a biomarker assessment that assessed pAkt levels in blood). The second step utilized permutation testing which involved 1000 computerized simulations in which study participants were randomly re-assigned to a treatment group, although the entire results data set of each subject was left intact.

Results:

The standard, pre-specified results analyses revealed that most measures trended for greater improvement with AMO-02/tideglusib than placebo including measures of social withdrawal (ABC-Social) and repetitive behaviors (RBS-R), as well as daily living skills (Vineland), memory (NEPSY) and sleep quality (CSHQ), with several measures reaching nominal significance.

The concordant trends analysis confirmed efficacy in 3 of the 7 outcome measures/endpoints involved in the analysis, with the remaining endpoints showing no worsening on AMO-02/tideglusib, and a pattern was evident in which AMO-02/tideglusib consistently outperformed placebo. The probability that this pattern occurred by chance alone was lower than 0.09; the exact value of the false-positive rate could be calculated using permutation testing. Two scenarios were run using the permutation testing approach and these revealed p-values of 0.07 and 0.007 in favor of AMO-02/tideglusib over placebo.

Conclusions:

An initial concordant trend analysis and subsequent permutation testing provided reiterative confidence about the affirming study findings that effectively established positive proof-of-concept for AMO-02/tideglusib as a potential treatment for ASD. Accordingly, it can be concluded that AMO-02/tideglusib merits further progression in clinical development in ASD.

179 **209.179** An Open Label and Double Blind Randomized Placebo Controlled Pilot Study of L1-79 [D,L Alpha-Methyl-Para-Tyrosine (DL-AMPT)] for the Treatment of the Core Symptoms of Autism Spectrum Disorder (ASD) in Adolescent and Young Adult Males

*J. Rothman[1], P. Halas[2], E. J. Bartky[3], T. Fischer[1] and **J. T. Megerian**[4,5], (1)Yamo Pharmaceuticals, New York, NY, (2)Sea Girt Pediatrics, Sea Girt, NJ, (3)Bartky HealthCare Center, Livingston, NJ, (4)Yamo Pharmaceuticals, Ladera Ranch, CA, (5)Neurology, CHOC (Childrens Hospital of Orange County), Orange, CA*

Background:

Catecholaminergic neurotransmitters play critical roles in many aspects of social, communication and emotional functions, ranging from regulating mood, anxiety, and pleasure to modulating attention, impulse control and response to sensory stimuli. Many of these functions are noted to overlap with behaviors affected in the Social-Communication Interaction (SCI) domain of ASD. L1-79 is a tyrosine hydroxylase inhibitor known to decrease catecholamine biosynthesis by inhibiting the conversion of tyrosine to dihydroxy-phenylalanine (DOPA), the rate limiting reaction in catecholamine synthesis

Objectives:

To determine if 100 or 200 mg of L1-79 given three times per day (TID) can improve deficits within the core symptom domains in adolescents and young adult males with ASD.

Methods:

Two cohorts of males between ages of 13 and 21, with a diagnosis of ASD confirmed by Autism Diagnostic Observation Scale-2 and Autism Diagnostic Interview-Revised were enrolled in either the 100 mg or 200 mg TID dose group. Five participants in each dose group received open label active drug for 28 days for additional safety testing utilizing EKG, urine and blood sampling. Another 15 and 16 subjects, respectively, were randomized in a 2:1 fashion to receive drug or placebo (PBO) for 28 days. Outcome measures included mean change from baseline to day 28 in the Clinical Global Impression of Severity (CGI-S), standard scores on the Vineland Adaptive Behavior Scale – 2 Socialization Domain (VABS-2-SD), Social responsiveness Scale – 2 (SRS-2), and Repetitive Behavior Scale - Revised (RBS-R). Mixed multiple repeated measures analyses were performed for measures that were taken at interim visits.

Results:

The study drug was well tolerated with no serious AEs or significant laboratory abnormalities. Although no results reached statistical significance for comparison against PBO, multiple assessment measures demonstrated improvements in aspects of social functioning for the 200 mg dose group. Mean changes comparing 200mg to PBO were as follows: CGI-S: -.8 vs. -.4, SRS-2 Social Motivation T-score: -10.6 vs. -3.8, VABS-2-SD: 7.6 vs. 1.5, respectively, SRS-2 Total: -7.7 vs -6.4, SRS-2 SCI: -7.6 vs -5.8, respectively. Additionally, trends of improvement in Repetitive Restrictive behaviors (RRBs) were noted in the SRS-2 RRB T-score (-7.6 vs -5.8) and the RBS-R Total Score (-18.1 vs -12.5) for 200mg vs PBO, respectively. Sameness behavior on the RBS-R was the largest contributor to improvement in the RBS-R (-4.7 vs -2.3, 200mg vs PBO, respectively).

Conclusions:

This small, 28-day pilot study of L1-79 demonstrated trends toward improvement in the core domains of SCI and RRB in ASD in adolescent and young adult males. Results suggest that modulation of catecholaminergic neurotransmitters in ASD may be a viable target for therapeutic intervention. A larger study in male and female adolescents and young adults with ASD is planned.

180 **210.180** Antigen-Driven Rat Model of Maternal Autoantibody Related Autism

***J. Van de Water**, MIND Institute, University of California, Davis, Davis, CA*

Background: Maternal autoantibodies reactive to proteins in the developing fetal brain have been previously described in a subset of mothers of children with autism spectrum disorder (ASD), but not in mothers of typically developing children.
Objectives: We recently developed an active immunization rat model of maternal autoantibody related (MAR) ASD that mimics those found in the mothers of children with ASD to directly assess the pathologic significance of prenatal exposure to epitope-specific autoantibodies, and to evaluate the impact of maternal autoantibody exposure on complex, reciprocal play behavior as well as longitudinal MRI and MRS spectroscopy of the brain.

Methods: We generated epitope-specific autoantibodies in female rats through a series of immunizations containing the immunodominant peptide epitopes of the four primary target proteins of MAR-ASD (LDH A and B, CRMP1, and STIP1). Control females were injected with saline/adjuvant only. Autoantibody-positive females were bred, and male and female offspring were tested for autism-relevant behaviors and developmental milestones from early postnatal through adulthood. We also evaluated adult MAR (N=8) and control offspring (N=8) evaluated with a pro-social motivation assay.

Results: Offspring prenatally exposed to MAR-ASD antibodies emitted fewer ultrasonic vocalizations as pups at postnatal day 12 (p=<0.05), spent less overall time engaged in social interaction as juvenile and young adults (p=<0.05), and specifically spent less time in reciprocal play behavior as juveniles (p=<0.05) and engaged in more self-grooming behavior as adults (p=<0.05). MAR offspring demonstrated differences in time-to-release of their dyad partner from a confinement chamber compared to controls.

Conclusions: The developmental trajectory of social impairments and repetitive behaviors observed in the MAR rats parallels features of human autism and lends support to prenatal autoantibody exposure as a risk factor for ASD. Further, the MAR rats appear to be less interested in the release of their dyad partners based on the **increase** in time to release from the confinement chamber over time.

181 **210.181** The Adaptive Immune Response in Children with ASD Correlates with Behavior Severity

P. Ashwood[1], *D. Rose*[2], *H. Yang*[3] *and M. Careaga*[4], *(1)MIND Institute, University of California, Davis, Davis, CA, (2)UC Davis M.I.N.D. Institute, Sacramento, CA, (3)MMI, UC Davis, sacramento, CA, (4)UC Davis/MIND Institute, Sacramento, CA*

Background: Dysregulated adaptive immune responses have been observed in the blood of individuals with autism spectrum disorders (ASD). These have included higher ratios of CD8:CD4 T cells, increased activation markers on the surface of T cells, increased lymphocyte proliferation in response to stimulation, the presence of antibodies reactive to brain proteins and increased production of inflammatory cytokines. Although the degree of dysregulation is associated with more severe behaviours few studies have tried to determine whether specific subphenotypes within ASD are more affected than others.

Objectives: To address the question of heterogeneity in immune responses, we sought to examine the diversity of immune profiles in young children with ASD and the association with behaviour. Moreover, to determine whether co-morbidity may affect immune response we sought to characterize peripheral T cell subsets in children with and without gastrointestinal (GI) symptoms compared to healthy typically developing children.

Methods: Peripheral blood mononuclear cells from children with ASD and from typically developing age-matched control subjects were stimulated with either lipopolysaccharide or phytohemagglutinin. Cytokine production was assessed after stimulation. Initially, the ASD study population was clustered into subgroups based on immune responses and assessed for behavioural outcomes. Secondly, we evaluated responses based on the presence or absence of GI symptoms.

Results: Children with ASD who had a proinflammatory profile based on lipopolysaccharide stimulation were more developmentally impaired as assessed by the Mullen Scales of Early Learning. They also had greater impairments in social affect as measured by the Autism Diagnostic Observation Schedule. These children also displayed more frequent sleep disturbances and episodes of aggression. Similarly, children with ASD and a more activated T cell cytokine profile after phytohemagglutinin stimulation were more developmentally impaired as measured by the Mullen Scales of Early Learning. Interestingly, children with ASD and GI symptoms displayed elevated T_H17 populations, while children with ASD who did not experience GI symptoms showed increased frequency of T_H2 populations. Both ASD groups showed evidence of reduced regulatory T cell populations compared to typically developing children.

Conclusions: Children with ASD may be phenotypically characterized based upon their immune profile. Those showing increased T cell activation/skewing display a more impaired behavioural profile than children with noninflamed or non-T cell activated immune profiles. These data also suggests that children with ASD may have deficits in immune regulation that leads to differential inflammatory T cell subsets. Overall, there may be several possible immune subphenotypes within the ASD population but that they commonly correlate with more severe behavioral impairments.

182 **210.182** Adaptive Cellular Immunity in the ASD Postmortem Brain

M. P. Anderson[1], *M. M. DiStasio*[2], *I. Nagakura*[3] *and M. J. Nadler*[2], *(1)Pathology and Neurology, Harvard Medical School/Beth Israel Deaconess Medical Center, Boston, MA, (2)Harvard Medical School/Beth Israel Deaconess Medical Center, Boston, MA, (3)University of California Davis, Sacramento, CA*

Background: Autism spectrum disorder (ASD) is estimated to affect 1 in 59 children by 8 years of age in the United States and yet, except for rare genetic causes, the etiology in most ASD cases remains unknown. The presence of increased inflammatory proteins and transcripts in the ASD brain indicates the innate immune response is activated in a large proportion of ASD cases.

Objectives: To evaluate for adaptive immune cells and damage typical of immune cell mediated cytotoxicity that could potentially drive an innate immune response in the ASD brain.

Methods: The quantity of immune cell subtype infiltrates, cytotoxic cellular debris, tissue loss and fibrosis were compared in ASD and control brains. Standard neuropathology diagnostics methods including histology and immunohistochemistry were extended with automated image segmentation to quantify identified pathologic features in the postmortem brains.

Results: Multifocal perivascular lymphocytic cuffs are found that contain increased numbers of lymphocytes in ~65% of ASD compared to control brains in males and females, across a range of ages, in most brain regions, and in white and grey matter, and leptomeninges. $CD3^+$ T-lymphocytes predominate over $CD20^+$ B-lymphocytes and $CD8^+$ over $CD4^+$ T-lymphocytes in the ASD brain. Importantly, the number of lymphocytes in these perivascular cuffs correlates to the quantity of astrocyte-derived round membranous blebs, a known cytotoxic reaction to targeted lymphocyte attack and a histologic feature so far unique to ASD. Consistent with an immune cell-mediated injury at perivascular CSF-brain barriers, a subset of white matter vessels have an expanded perivascular space (with jagged contours) and increased perivascular collagen in ASD compared to control brains. Similar T-lymphocyte and astrocyte bleb pathology is observed in subarachnoid and pial surfaces of the cerebral cortex in ASD.

Conclusions: The findings suggest dysregulated cellular immunity may target the damage of astrocytes at foci along the CSF-brain barrier in many cases of ASD.

183 **210.183** Activation of Microglia Mediates ASD like Phenotype in Mice Following in Utero Exposure to Anti-Caspr2 Antibodies

L. Brimberg[1], *S. Mader*[2], *D. Comoletti*[3], *P. T. Huerta*[4], *B. Volpe*[5] *and B. Diamond*[6], *(1)Center for Autoimmune and Musculoskeletal Diseases, The Feinstein Institute for medical Research, Manhasset, NY, (2)The Feinstein Institute for Medical Research, Manhasset, NY, (3)Department of Neuroscience and Cell Biology Rutgers - Robert Wood Johnson Medical School, Rutgers, NJ, (4)Laboratory of Immune & Neural Networks, Feinstein Institute for Medical Research, Manhasset, NY, (5)Laboratory of Biomedical Science, The Feinstein Institute for Medical Research, Manhasset, NY,*

(6)The Feinstein Institute for Medical Research, Manahasset, NY

Background:
Autism Spectrum Disorder (ASD) is a devastating condition with an incidence that continues to rise worldwide. The rising incidence points to environmental factors. We have been particularly interested in the contribution of maternal antibody to ASD, as we observed that over 10% of mothers of an ASD child harbor anti-brain antibodies. We demonstrated that one such pathogenic maternal antibody is anti-Caspr2 antibody, a monoclonal antibody generated from a mother with anti-brain antibodies and an ASD child. A single in utero exposure to this antibody led to brain and behavior abnormalities in male but not in female mice. Since we determined that approximately 40% of mothers with an ASD-child and with anti-brain reactivity expressed anti-Caspr2 reactivity, anti-Caspr2 reactivity might be dominant brain specificity and have an important translational impact.

Objectives:

To understand how in utero exposure to anti-Caspr2 antibodies causes persistent neurologic abnormalities.

Methods:

We have developed a new model with endogenous antibody production in which dams harbor anti-Caspr2 antibodies throughout gestation, to better mimic the human condition, and to ascertain the pathogenicity of a spectrum of anti-Caspr2 antibodies. Six week old C57Bl/6 female mice were immunized with the extracellular region of human Caspr2. Control female mice are immunized with adjuvant only. IgG titers against Caspr2 are determined by a cell based assay against both human and mouse Caspr2. When antibody titers to mouse Caspr2 are 1:3000 immunized mice are mated with naïve males to generate timed pregnancies. We assessed neuropathology and behavior of mice exposed in utero to polyclonal anti-Caspr2 antibodies.

Results:

Male, but not female, fetuses of dams harboring anti-Caspr2 antibodies showed thinning of the cortical plate, reduced proliferating cells at E15.5, and abnormal neuronal migration similar to our previous results in male fetuses exposed in utero to maternal monoclonal anti-Caspr2 antibody. Adult male but not female mice born to dams harboring anti-Caspr2 antibodies showed an an impaired interest in social novelty in the social preference test, and repetitive/ stereotypic behavior; they buried significantly more marbles than control mice in the marble burying test, and spent more time grooming. We found that the brain of mice exposed in utero to anti-Caspr2 antibodies exhibited decreased dendritic complexity of excitatory neurons. A potential mechanism for decreased dendritic complexity is engulfment of dendritic processes by activated microglia. Indeed, we observed activated microglia identified by localization of CD68 with Iba1, cell shape and number of extended processes. We are currently testing if depletion of microglia in the offspring will prevent the decreased dendritic arborization.

Conclusions:

We show in a new mouse model that exposure in-utero to anti-Caspr2 reactive antibodies induces neurodevelopmental effects in the offspring that can be observed already during the embryonic stage. These antibodies lead to an ongoing activation of microglia in the adult mice. Microglia are druggable targets; therefore modulating microglia might be a potential new therapy.

184 **210.184** Autism and Exposure to Zica Virus: Report of Two Cases

***M. P. Ponde**, BAHIANA School of Medicine and Public Health, Salvador, Brazil*

Background: Some brain lesions have been described in association with maternal exposure to Zika Virus infection and have started with reports of microcephaly. Studies with rats suggest that mild infections in pregnancy can lead to lesions that are not apparent at birth, and then present as neurobehavioral deficits, such as locomotor and cognitive deficits, associated with the brain with thinner cortical layer 1 and increased astrogliosis. The correlation between viral infections in pregnancy and autism has been suggested for rubella, measles, mumps and influenza viruses. To date, no cases of autism related to exposure to Zika virus have been reported in the literature.
Objectives: Described cases of autism in wish mothers were affected by the Zika virus during pregnancy.

Methods: In this article, we described two cases of autism, in both mothers were affected by the Zika virus infection in the first trimester of pregnancy and the children did not present microcephaly.

Results: Case 1. Male child, 3 years old, 41 year old father and 28 year old mother. Autism Spectrum Disorder, nonverbal, presence of oppositional behavior. ADOS-2 score 10 (High); language and communication score 9; reciprocal social interaction score 17; Play score 6; repeated behavior and restricted interest score 7; other abnormal behavior score 1 (tantrums, aggression, negative or disruptive behavior). Case 2 Male child 2 years and 6 months. Age of the father: 30 years; Mother's age: 33 years. Autism Spectrum Disorder Mild, verbal few words. ADOS-2 score 6 (moderate); Language and communication score 5; reciprocal social interaction score 16; Play score 2; repeated behavior and restricted interest score 0; Other abnormal behavior score 0.

Conclusions: Neuro inflammation seems to modulate cortical and cerebellar functions through the activation of microglia and astroglia and the production of proinflammatory cytokines in some cases of autism. In the cases described, both mothers were infected with Zika Virus in the first trimester of pregnancy. In Case 1 autism symptoms are more severe, and the mother was also exposed to repetitive UTIs during pregnancy and to the use of antibiotics. This child also presents an anatomical alteration, with agenesis of fingers, which may be due to the use of antibiotics at the time of the entire pregnancy.

185 **210.185** Cytokine Alterations on Clinical Characteristics in Chinese Children with Autism Spectrum Disorder

ABSTRACT WITHDRAWN

Background:
Autism spectrum disorder (ASD) is a neurodevelopmental disorder in which genetics, together with environmental risk factor play a key aetiological role. Multiple evidence indicates a link between immune dysfunction and ASD. However, few data showed the relationships between cytokine level and clinical characteristics of Chinese ASD patients.

Objectives:

To investigate cytokines alterations in Chinese ASD children with regression and allergy.

Methods:

We reanalyzed our previously published data for case-control study. ASD children who were diagnosed and qualified for the inclusion criteria were recruited in the research as experimental group, typically developing children from a Kindergarten and early childhood education center as control group. Research method: 11 cytokines plasma levels were measured according to Miliplex BMS protocol. The clinical characteristics of ASD group: We recorded the medical history including regression and allergy.

Results:

The cohort included 65(55 male) ASD children and 42(28 male) TD children, aged 19 to 79 months.

1)The results of plasma cytokine levels showed: Plasma TNFα and Eotaxin levels were significantly higher in ASD group (TNFα: median 16.26, range 6.89–28.45pg/mL, P =0.016; Eotaxin: 72.18, 23.87–490.69pg/mL, P=0.045)than in TD group(TNFα: 14.19, range 7.40–25.21pg/mL, P =0.016; Eotaxin:55.72, 19.24-170.94pg/mL). There was a trend for Plasma TGF-β1(ASD: 5337.0, 931.67–34107.0pg/mL; TD: 2680.0, 574.08–18194.0pg/mL, P = 0.066).TGF-β1 was significantly increased in ASD male group than TD group(ASD: 5411.0, 931.67–34107.0pg/mL; TD: 2681.0, 838.28–16695.0pg/mL, P = 0.033).

2) 17 of 65 ASD children had regression. Compared with ASD children with no regression(ASDnr) and TD children, ASD children who had regression(ASDr) had higher trend for plasma TGF-β1(ASDr:7359.0, 1164.0–24649.0pg/mL; ASDnr:3413.0, 931.67–34107.0pg/mL; TD:2680.0, 574.08–18194.0pg/mL, P=0.070) and Eotaxin (ASDr:72.42, 23.87–490.69pg/mL;ASDnr:71.0, 23.87–192.31pg/mL; TD: 55.72, 19.24-170.94pg/mL, P=0.056). For male, the increase of TGF-β1 was most significant in ASDr, almost three-fold higher than TD (ASDr:7359.0, 1164.0–24649.0pg/mL; ASDnr:4452.0, 931.67–34107.0pg/mL; TD: 2681.0, 838.28– 16695.0pg/mL,P=0.039).

3)Since we did not have data of TD children for allergic history, we compared cytokines of ASD children with allergy (ASDa: 29/65) and non-allergy (ASDna: 36/65). Compared to ASDna, ASDa showed higher TNFα level (ASDa:17.14, 6.89–26.60pg/mL; ASDna:15.6, 7.93–28.45pg/mL, P =0.038).

Conclusions:

The pilot findings showed that TGF-β1,TNFα and Eotaxin may have associations with neurodevelopment progression of children, especially in boys. TGF-β1 and TNFα may have potential role in the mechanism of regression and allergy in ASD in Chinese population.

186 **210.186** Systematic Profiling of Viral Antibodies in Children with Autism Spectrum Disorder (ASD)

L. Hewitson[1], *M. Devlin*[1] *and H. B. Larman*[2], *(1)The Johnson Center for Child Health and Development, Austin, TX, (2)Johns Hopkins University, Baltimore, MD*

Background:

Animal studies suggest that maternal viral exposure results in immune activation altering the activity of multiple genes/associated pathways in the developing fetal brain. Importantly, many of these genes are key to developmental processes that occur before birth, demonstrating how maternal viral exposure could increase the risk of having a child with ASD. Similarly, post-natal viral exposures, particularly those that cause respiratory tract infections (RTIs), may also be an ASD risk factor.

Objectives:

The aim of this study was to use VirScan to perform a systematic analysis of viral antibodies in sera from boys (2-9 years) with and without ASD to examine their post-natal viral exposure histories.

Methods:

Subjects included 100 boys with ASD (mean age 5.92, SD 1.95 years) and 100 typically developing (TD) boys as controls (mean age 5.99, SD 2.17 years). An ASD diagnosis was confirmed using the ADOS and ADI-R. Analysis of viral antibodies in serum samples was performed using VirScan, which combines DNA synthesis and bacteriophage display and allows for the systematic detection of over 200 viruses from more than 20 different virus families. Data were analyzed using Fisher, t, and Wilcoxon rank tests.

Results:

VirScan detected antibodies that interacted with peptides from 266/499 (53.3%) viruses. Viral peptide hits reported for children both with and without ASD are shown in Table 1. Not surprisingly, 100% ASD and 99% control subjects had antibodies to rhinovirus, the common cold. There were also high frequencies of viruses that cause various gastrointestinal and RTIs such as adenoviruses, herpesviruses, RSV and enteroviruses. There were no significant differences between ASD and controls for any viral antibodies detected after adjusting for multiple hypothesis testing. Interestingly, very low numbers of viral peptides to hepatitis B, measles, mumps, rubella, and rotavirus (from either the vaccine or viral infection) were detected. This could be due to the original immune response being low, the antibody response to these vaccines waning over time, a depletion of long-lived memory B cells, or that VirScan cannot accurately capture this data. Further analysis of the effects of age on viral exposures in ASD is underway.

Table 1: Summary of the some of the most commonly detected antibodies in children with and without ASD. Data represents the percentage of subjects with antibodies detected against at least one peptide from each virus.

Virus species	**Control %**	**ASD %**
Rhinovirus_A	100.0	99.02
Human adenovirus_C	90.20	71.57
Human respiratory syncytial virus	88.24	87.25
Human herpesvirus-6B	75.49	73.53
Enterovirus_B	63.73	61.76
Human herpes virus-5	52.94	49.02
Enterovirus_A	50.98	51.96
Variola virus	50.00	32.35

Norwalk virus	49.02	53.92
Human herpesvirus-4	42.16	38.24
Enterovirus_C	29.41	33.33
Human adenovirus_B	27.45	14.71
Human influenza virus-3	21.57	16.67
Human herpes virus-7	21.57	22.55
Influenza A virus	20.59	14.71
Rotavirus_A	12.75	7.84

Conclusions:

These data suggest that VirScan may be useful in examining viral histories of children with ASD. Future studies should focus on comparing prenatal maternal samples with those of the newborn to further elucidate putative prenatal viral causes of ASD, as well as performing viral surveillance throughout post-natal development.

187 **211.187** Benefits of a Fitness Program for Individuals with Autism Spectrum Disorder: Physical, Cognitive, and Behavioral Outcomes

***S. L. Jackson**, T. Winkelman, E. Hamo, D. Stahl and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Individuals with autism spectrum disorder (ASD) engage in significantly less physical activities than typically developing peers (e.g. Pan, 2009). This sedentary lifestyle can result in serious negative consequences on physical (e.g. cardiovascular disease, obesity), behavioral (e.g. emotional regulation, sleep disturbance), cognitive (e.g. memory, concentration), and emotional (e.g. stress, depression, anxiety) well-being -- all common areas of difficulty in ASD. While there is an abundance of research demonstrating that regular physical activity can have a positive impact on the above issues in typically developing individuals (Fedewa & Ahn, 2011), research on this topic for individuals with ASD is limited.
Objectives: The current study examined the physical, behavioral, cognitive, and emotional benefits of a specialized physical exercise program in a sample of individuals with ASD.

Methods: Data was collected on 11 individuals with ASD (82% male; mean age=14.73 years, *SD*=6.59) from the ASD Fitness Center in Orange, CT, at baseline and following 15 workout sessions. Physical data (e.g. body mass index (BMI), exercise assessments) were collected by center staff. Behavioral/cognitive/emotional data were collected by research staff via parent-report questionnaires: the Child Sleep Habits Questionnaire (CSHQ; sleep disturbances), Social Responsiveness Scale (SRS-2; social abilities/restricted and repetitive behaviors), and the Behavior Assessment System for Children (BASC-3; behavioral and emotional problems/adaptive skills/executive functioning). The average duration between baseline and follow-up data collection was 14.5 weeks (*SD*=7.23). Additional data collection and BASC-3 analyses are ongoing.

Results: Preliminary analyses found significant improvement in core strength [increased time holding a plank position, $t(10)=-2.4$, $p<.05$] and marginal changes in lower-body strength [increased number of hurdles, $t(10)=-2.1$, $p=.06$; increased hamstring bridge time, $t(10)=-2.2$, $p=.06$]. Restricted and repetitive behaviors were significantly reduced following the 15 workout sessions [$t(10)=2.5$, $p<.05$]. Though average CSHQ scores were reduced from baseline ($M=43.3$, $SD=8.4$) to follow-up ($M=41.6$, $SD=6.8$), this difference was not statistically significant. Reductions in BMI following the program were associated with reduced sleepiness during the day ($r=0.64$, $p<.05$) and improved social cognition ($r=0.61$, $p<.05$).

Conclusions: Preliminary results provide empirical support for the effectiveness of an ASD-specific exercise program in improving physical strength and reducing restricted and repetitive behaviors in individuals with ASD. These preliminary findings additionally suggest that reductions in BMI may improve daytime sleepiness and social cognition in this population. Forthcoming analyses will explore the behavioral and emotional impacts of this exercise program, broadening our understanding of the benefits of regular physical activity for individuals with ASD. Considering the potential wide-ranging benefits that regular physical activity can have on the well-being of individuals with ASD, it is critical for more research to be done on this topic to inform development of, and participation in, exercise programs designed specifically for this population.

188 **211.188** Best Practices in Supporting Social Participation of Young Adults with Autism Spectrum Disorder (ASD) : A Systematic Review.

***M. Couture**[1], E. L. Bussières[2], J. Trépanier[3], O. Laverdière[4], M. H. Poulin[5], D. St-Laurent[6], J. Berbari[7] and C. Dumont[8], (1)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, Canada, (2)Psychology, Université du Quebec à Trois-Rivières, Trois-Rivières, QC, Canada, (3)Faculté de médecine et des sciences de la santé, Université de Sherbrooke, Sherbrooke, QC, Canada, (4)FAculté de Médecine et des sciences de la santé, Université de Sherbrooke, Sherbrooke, QC, Canada, (5)Psychoeducation, UQAT, Rouyn-Noranda, QC, Canada, (6)Psychoeducation, UQAT, Royn-Noranda, QC, Canada, (7)FAculté de médecine, Unviersité de Sherbrooke, Sherbrooke, QC, Canada, (8)Rehabilitation, UQTR, Trois-Rivières, QC, Canada*

Background:

The majority of ASD studies focuses on early childhood and early interventionwhile the challenges associated with autonomy and independent living is a major issue for adults with ASD.

Objectives: The purpose of this systematic review (SR) is to document the effectiveness of interventions to support social participation of young adult with autism (16-40 years old).

Methods:

A comprehensive literature search was conducted to identify published articles and unpublished dissertations, using the following databases

ProQuest, Medline, PsycInfo, Cinhal, ERIC. The research covered the period from 1 January 2000 to 1 September 2018. Two persons independently screened articles for eligibility. Studies were included if they: 1) include more than 10 participants ; 2) focuses on at least one aspect of transition to adulthood, including social relations, employment and independent living. Critical appraisal of included studies was done using the Scientific Merit Rating Scale (National Autism Center, 2015) by two independent persons.

Results: Fourteen studies were retained, evaluating work-related interventions (10 studies), independent living programs (3 studies) and a leisure program (1 study). Methodological quality varies greatly across studies. Among high quality studies, three different interventions appear promising: a leisure program and two programs related to work, including a virtual training to job interviews, and a school-based employability program including an internship.

Conclusions: This SR suggests that interventions targeting transition to adulthood may be beneficial; it also highlights the need for more research, especially regarding the effectiveness of programs targeting independent living

189 **211.189** Beyond Fidelity: Measuring Implementation in a Multi-Faceted School-Based Intervention

J. R. Steinbrenner[1], *S. Odom*[1], *L. J. Hall*[2] *and K. Hume*[1], *(1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)Special Education, San Diego State University, San Diego, CA*

Background: Measuring implementation of interventions is a critical but understudied area in autism research. Many intervention studies report fidelity, but some types of interventions, such as complex service interventions (CSIs; Komro, 2018) warrant a more robust measure of implementation that captures process and content of these multi-faceted interventions (Cordrey et al., 2013. The Center on Secondary Education for Students with ASD (CSESA) developed a comprehensive treatment model for high school students with ASD that is a CSI (Hume & Odom, under review). The CSESA model involves professional development (training and coaching) to support a process of assessment, planning, implementation, and evaluation at the school and student levels. The CSESA model addressed four domains (academics, social, independence & behavior, and transition) using ten intervention components.

Objectives: The objectives of this study are to: (1) describe a multi-featured approach to measuring implementation for CSIs, (2) examine the variability in implementation profiles within the CSESA group, and (3) examine differences in implementation between the CSESA group and services-as-usual (SAU) group.

Methods: This randomized control trial included 60 schools that were randomly assigned to CSESA or SAU. There were 547 student participants and 579 school staff participants across the 60 schools. The CSESA implementation index measured implementation at three different levels of implementation and assessed 7 features across those three levels: (1) delivery of CSESA intervention to schools by CSESA research staff (training, coaching), (2) implementation of CSESA intervention by school staff (intervention quality, teaming, school-level planning), and (3) reception of CSESA interventions by students (intervention dosage, student-level planning). The seven features were measured using a variety of tools (e.g., coaching log, fidelity rating scales, planning artifacts) which provided an implementation profile (see Table 1 for further description). The feature scores were converted to scaled scores (0-3 range) based on a priori decisions about implementation quality for CSESA, and then the scaled scores were weighted and used to calculate a single implementation index score for each school.

Results: The implementation index profile scores for the CSESA schools showed variability within and across the raw and scaled feature scores (see Table 2 for descriptive statistics). Six out of the seven features had scaled scores that spanned from either 0 to 3 or 1 to 3, and the raw scores exhibited similarly wide ranges. However, most schools scored in the good (2) or ideal (3) implementation range for most features. For the single implementation index scores, there was a significant difference between the mean scores for the CSESA (2.07) and SAU (0.47) schools ($t=28.13$, $p<.001$).

Conclusions:

The multi-featured CSESA implementation index was successfully used in the context of a school-based RCT to capture a range of implementation within the intervention group, as well as differences between the intervention and control group. The development and use of an implementation profiles and index that captures information about the process and content of a CSI is critical in supporting intervention research, implementation science, and dissemination of comprehensive treatment models or other similarly complex interventions for individuals with ASD.

190 **211.190** Characteristics of Adolescent Girls with ASD Participating in a Social Skills Intervention

M. Ferland[1], *B. L. Ncube*[2], *J. M. Bebko*[3], *N. Bardikoff*[4], *M. Thompson*[4], *M. Spoelstra*[4], *J. Read*[5] *and S. Molica*[4], *(1)York University, Toronto, ON, CANADA, (2)Psychology, York University, Toronto, ON, Canada, (3)York University, Toronto, ON, Canada, (4)Autism Ontario, Toronto, ON, Canada, (5)Autism Ontario, Richmond Hill, ON, Canada*

Background: Research on the social relationships of adolescent girls with autism spectrum disorder (ASD) is limited. However, girls with ASD may have some social advantages over boys. For example, Kreiser and White (2014) suggests that social and cultural influences encouraging girls to be more empathic and nurturing can have an impact on the expression of ASD characteristics in females, as well as on how the behaviour of females with ASD is perceived by others. Cook, Ogden, and Winstone (2018) found that adolescent girls were able to "mask" their ASD symptoms by successfully adopting the tone and mannerisms of other neurotypical girls to fit in. However, while "masking" provided the girls with a superficial social competence, the girls continued to experience social isolation and peer conflict. Overall, despite some perceived advantages over boys, girls with ASD continue to struggle with social relationships (Fogo & Webster, 2017).

With the preponderance of males in the ASD population, less is known about specific outcomes for girls with ASD following social skills interventions. The Program for the Education and Enrichment of Relationship Skills (PEERS) is a 14-weeks manualized social skills training intervention for adolescents and young adults, which includes a teen and a parent component occurring simultaneously.

Objectives: The present study examines sex differences in the outcomes of adolescents with ASD who participated in the PEERS program through Autism Ontario.

Methods: 33 girls between the ages of 13 and 19 ($M = 14.90$, $SD = 1.44$) and 80 boys between the ages of 13 and 18 ($M = 14.75$, $SD = 1.45$) who participated in the PEERS program in Ontario between Winter 2015 and Summer 2018 were included. Parents and children complete several measures before and after participation in the program. Measures evaluated social skills knowledge, friendship quality, and social anxiety.

Results: At baseline, parents of girls rated their children as having significantly greater social anxiety than parents of boys; $t(51.46) = -3.035$, $p = .004$. Following intervention, both groups demonstrated decreases in social anxiety and, while parents of girls continued to rate their children as having greater social anxiety, the differences between the groups were no longer significant ($p = .182$). At baseline, girls tended to report less conflict between themselves and their "best friend" when compared to boys; however, this difference was not statistically significant ($p = .089$). Differences in how girls and boys rated conflict in their relationships with their best friends were maintained following participation in the PEERS program ($p = .086$). Lastly, adolescents demonstrated similar social skills knowledge at baseline ($p = .553$); however, girls demonstrated significantly greater improvements in social skills knowledge following the PEERS intervention compared to boys; $t(57.15) = -2.687$, $p = .009$.

Conclusions: Our results support the idea that adolescent girls and boys with ASD differ in their social experiences and skills, and, importantly, they may also differ in their response to a time-limited social skills intervention. A more refined approach, with information individualized for boys or girls may be warranted.

191 **211.191** Cognitive Behaviour Therapy for Anxiety in Children with Autism Spectrum Disorder: Predictors of NON-Response to Treatment

K. McFee[1], *J. Baraskewich*[2], *C. A. McMorris*[2], *K. Johnston*[1] *and M. McConnell*[1], *(1)BC Children's Hospital, Vancouver, BC, Canada, (2)Werklund School of Education, University of Calgary, Calgary, AB, Canada*

Background: Internalizing mental health issues, such as anxiety and depression, are common, often debilitating conditions for children and youth with autism spectrum disorder (ASD; Simonoff et al., 2008). The complex, pervasive, and heterogeneous clinical symptoms of youth with ASD and co-occurring psychiatric disorders makes treatment of mental health issues challenging (Wood et al., 2006). Facing Your Fears (FYF) is a well-established, evidence-based modified cognitive behaviour therapy (CBT) group that has been developed for children and youth with ASD (Reaven et al., 2009). Findings from randomized controlled trails have shown that anxiety symptoms, social difficulties, and emotion dysregulation improve in children and youth with ASD who participate in FYF, with these improvements maintained 12 months post-intervention (Reaven et al. 2012). While the majority of FYF participants show reductions in anxiety symptoms and less interference in daily life, a small subset of FYF participants (approximately 20% of children and adolescents) are not responsive to the treatment (Reaven et al., 2009). To date it is unknown why some individuals with ASD are responsive to FYF and others are not.

Objectives: The present study aims to examine the demographic and clinical predictors of responsiveness to FYF. Consistent with previous research in pediatric anxiety, it is expected that sex, type of anxiety disorder, severity of anxiety symptoms at pre-assessment, and presence of parental psychopathology will be associated with poorer outcomes after FYF.

Methods: 51 children and youth between 8 and 13 years of age participated in FYF groups over a 5-year period. Children/youth and their caregivers completed a variety of measures before (pre) and after (post) participating in FYF. Specifically, anxiety type, symptoms, and severity (Spence Children's Anxiety Scale and the Anxiety Disorder Interview Scale [ADIS]), presence of other psychiatric disorders (ADIS, Behaviour Assessment System for Children -2, Child Depression Inventory), parent psychopathology (State Trait Anxiety Inventory), and ASD symptom severity (Social Communication Questionnaire) were assessed. Demographic variables (age, sex) and other clinical variables (IQ) were obtained prior to starting the group.

Results: Data have been collected and analyses will be completed in Winter 2019. Using pairwise correlations and hierarchical logistic regression analyses we will identify which demographic and clinical factors are associated with non-response to FYF.

Conclusions: FYF has shown to be effective in reducing anxiety symptoms for most children and youth with ASD (Reaven et al., 2012). Determining what factors are associated with treatment non-response will be valuable in providing appropriate, effective, targeted treatment for youth with ASD and co-occurring mental health issues, ultimately improving the care, outcomes, and quality of life of youth with ASD.

192 **211.192** Cognitive Behavioural Therapy for Anxiety Disorders in Children with Autism Spectrum Disorder: A Randomized Controlled Trial.

T. R. Kilburn[1], *M. J. Sørensen*[2], *M. Thastum*[3], *R. M. Rapee*[4], *C. U. Rask*[2], *K. B. Arendt*[3] *and P. H. Thomsen*[1], *(1)Department of Child and Adolescent Psychiatry, Research Unit, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (2)Department of Child and Adolescent Psychiatry, Aarhus University Hospital, Psychiatry, Aarhus N, Denmark, (3)Department of Psychology and Behavioural Science, Aarhus University, Aarhus C, Denmark, (4)Centre for Emotional Health, Department of Psychology, Macquarie University, Sydney, Austria*

Background: Autism spectrum disorder (ASD) is found in approx. 1-2% of the population and includes core symptoms that affect general and social development. A high risk of developing co-morbid disorders is prominent. It is thought that up to 60% of children with ASD suffer from different anxiety disorders which can further negatively influence educational, social and general development together with quality of life.
Objectives: The main goal of this study is to examine the effectiveness of a manualised cognitive behavioural therapy program (CBT) adapted to children with ASD in a non-English general psychiatric hospital setting.

Methods: The study is a randomized controlled trial with intention to treat analysis. Forty-nine children with ASD and anxiety, aged 8 to 13 years from a public child psychiatric health clinic are randomly assigned to either an intervention group or a waitlist control group. After the waitlist period the control group will receive intervention as well.

The group based manualised CBT intervention consist of The Cool Kids Anxiety Program: Autism Spectrum Disorder Adaptation, 2nd edition (Cool Kids ASD).

Outcome measures are collected pre, post-treatment and at 3 month follow up and include scores from a semi-structured diagnostic anxiety interview, together with parent, child and teacher questionnaires on children's anxiety symptoms, life interference, children's automatic thoughts, and social and adaptive skills.

Results: This is an ongoing study and final results will be available for presentation at the conference. However, results from a prior feasibility study showed that 55.5% of the children participating recovered and no longer met the criteria for their primary anxiety diagnosis after the treatment. This number rose to 77.7% at follow-up. Compliance to the program was high and 88.8% of the families found the program to be useful and would recommend it to other families in a similar situation.

Conclusions: This feasibility study suggests that the transition of the group program 'Cool Kids ASD' from research environments to non-English standard child psychiatric clinical settings is possible. The randomized study might confirm this efficiency and efficacy of the program in a larger sample.

Structured intervention like the manualised CBT group program might not only improve the main presenting difficulty, but also other aspects of the participants' functioning such as peer relationships. Training anxiety reduction skills and thus, decreasing anxiety in children with ASD using the manualised CBT program has the potential of preventing relapse and ensuring better psychosocial development for the child in general.

193 **211.193** Community Implementation of Facing Your Fears: A Cognitive Behavioural Therapy Program for Anxiety in Children with ASD

***B. Drouillard**, A. Solish, N. Klemencic, A. Ritzema, V. Nolan, M. Pilkington, E. Anagnostou and J. A. Brian, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Comorbid anxiety disorders are common among youth with high functioning Autism Spectrum Disorder (ASD; White, Oswald, Ollendick, & Scahill, 2009); however, there are few interventions demonstrated to be effective with this population. Facing Your Fears (FYF) is a manualized cognitive-behavioural therapy (CBT) program for anxiety, designed specifically for youth with high functioning ASD (Reaven, Blakely-Smith, Nichols, & Hepburn, 2011). Although FYF has demonstrated efficacy in research/hospital settings (Reaven, Blakely-Smith, Culhane-Shelburne, & Hepburn, 2012), its effectiveness when implemented in community settings is not well established.
Objectives: To evaluate the effectiveness of the FYF program implemented in community versus hospital-based settings.

Methods: Participants were 105 parent-child dyads (51 from the hospital setting and 54 from community settings). Children (76 boys, 29 girls; age range = 6.92 – 15.30 years; M_{age} = 10.47 years; *SD* = 1.75) had a diagnosis of ASD, broadly average cognitive functioning, and significant anxiety symptoms. Participants completed the Screen for Child Anxiety-Related Emotional Disorders (SCARED, Child and Parent; Birmaher, Brent, Chiappetta, Bridge, Monga, & Baugher, 1997) and the Spence Children's Anxiety Scale (SCAS, Child and Parent; Spence, 1998) pre- and post-intervention. Examination of baseline participant characteristics, using one-way ANOVAs, revealed that the only pre-treatment characteristic differing significantly across settings was child age, with children in the hospital setting being significantly younger (*M* = 10.08 years, *SD* = 1.71) than children in the community (*M* = 10.87 years, *SD* = 1.72; $F(1, 103) = 5.60$, $p = .02$). One-way ANCOVAs controlling for child age were therefore used to demonstrate pre-intervention equivalence between hospital-based and community-based participants on measures of anxiety and other behavioural difficulties.

Results: Within hospital-based groups, paired samples t-tests revealed significant reductions in anxiety from pre- to post-intervention on the SCAS- Parent Report, $t(50) = 4.75$, $p < .001$; SCAS-Child Report, $t(52) = 4.23$, $p < .001$; SCARED- Parent Report, $t(50) = 6.38$, $p < .001$; and SCARED- Child Report, $t(50) = 3.62$, $p = .001$. Similarly, within community-based groups, paired samples t-tests revealed significant reductions in anxiety from pre- to post-intervention on the SCAS- Parent Report, $t(48) = 3.97$, $p < .001$; SCARED- Parent Report, $t(46) = 5.05$, $p < .001$; and SCARED- Child Report, $t(45) = 2.58$, $p < .05$. Reductions in anxiety noted on the SCAS- Child Report in the community-based sample failed to reach significance, $t(49) = 1.62$, $p = .11$. ANCOVAs controlling for age revealed no significant differences in pre-post intervention change scores between participants in hospital and community-based FYF groups on the SCAS- Parent Report, $F(1, 97) = .189$, *ns*; SCAS- Child Report, $F(1, 100) = 1.124$, *ns*; SCARED- Parent Report, $F(1, 95) = .072$, *ns*; and SCARED- Child Report, $F(1, 94) = 2.139$, *ns*.

Conclusions: Findings provide support for the effectiveness of the FYF program when implemented in community settings. Given the similar reductions in anxiety symptoms observed among participants in hospital- and community-based groups, community implementation of FYF is a feasible and effective means of improving access to evidence-based anxiety intervention for children with high functioning ASD.

194 **211.194** Comparative Effectiveness of Therapeutic Riding and Stress Management Program on Salivary Cortisol and Heart Rate Variability of Youth on the Autism Spectrum

***E. Kemeny**[1], D. Hutchins[2], C. Gramlich[3], S. V. Burk[4], D. Singhabahu[5], E. Jones[2], A. Kronyak[2] and J. Deitrich[1], (1)Slippery Rock University, Slippery Rock, PA, (2)Recreational Therapy, Slippery Rock University, Slippery Rock, PA, (3)College of Health Environment and Science, Storm Harbor Equestrian Center, Slippery Rock, PA, (4)Equine Science, Otterbein University, Westerville, OH, (5)Mathematics and Statistics, Slippery Rock University, Slippery Rock, PA*

Background: For youth who are transitioning into adulthood with autism spectrum disorder (ASD), elevated stress levels and lack of coping mechanisms (Plessow, Fischer, Kirschbaum, & Goschke, 2011) relating to the core symptoms of autism become barriers to health and wellness (Hong, Bishop-Fitzpatrick, Smith, Greenberg, & Mailick, 2016). Limited research with younger children, ages 5-15, suggests that therapeutic riding (TR) improves gross motor and postural skills (Hawkins, Ryan, Cory, & Donaldson, 2014), spontaneous verbalization (Holm et al., 2014), irritability, hyperactivity, social cognition, and receptive communication skills (Ajzenman, Standeven, & Shurtleff , 2013) as well as quality-of-life (Lanning, Baier, Ivey-Hatz, Krenek, & Tubbs, 2014). A paucity of research exists with regard to young adults (from 14-25) and the impact of TR on emotional regulation or stress level (O'Haire, 2012).
Objectives: The research question concerns the comparative effectiveness of stress management (SM) techniques and Therapeutic Riding (TR) on stress levels of adolescents with ASD. The objective was to better understand the impact of TR and SM program as compared to a control phase in the same adolescent.

Methods: The study compares an evidence-based stress management protocol (HeartMath) to a TR protocol to no treatment control for 27 young adults ages 13-22 with ASD in a randomized three-period crossover trial. All interventions were one hour in length for ten consecutive sessions and administered by the same CTRS with a certification appropriate to the intervention (PATH or HeartMath certification). Participants were randomly assigned to the order in which they receive TR, HeartMath (HM), and no treatment control. Before and after each of the three 10-week periods, self-reported stress levels (Cohen et al., 1983) and salivary cortisol levels were measured. Salivary cortisol was measured over two consecutive days at four time points (Rising, 30 minutes after, session, and bedtime). Cortisol levels were also measured before and after each intervention session. Heart rate variability (HRV) was measured during each session using an emwave Pro sensor. Multivariate analysis of variance with one within-groups factor (time) and between-groups factors (TR vs. HM vs. control) was used.

Results: Analysis revealed a greater difference ($p < .05$) of self-reported stress in the TR phase than the HM phase. Coherence levels (HVR) were higher during the HM stress management sessions than TR sessions. There was a statistically significant decrease ($p < .05$) between the pre to

post mean cortisol values for TR sessions and HM sessions. While the mean difference scores between pre and post TR cortisol are larger than mean difference scores for HM, no statistically significant difference exists (p = .17). When comparing mean baseline to follow-up for TR to control, cortisol was reduced during the 30 minutes post awakening in the therapeutic riding. Further analysis will be focused on trends in individual response over phases.

Conclusions: While it is temporary, TR and HM are equally beneficial in decreasing cortisol levels. Both programs are more effective in decreasing salivary cortisol and self-reported stress than a period without intervention. For adolescents with ASD, pre-screening may determine the more effective intervention.

195 **211.195** Comparison of Therapeutic Alliance across Informants: Therapist Versus Independent-Observer Ratings

***F. H. Roudbarani**, C. S. Albaum and J. A. Weiss, Psychology, York University, Toronto, ON, Canada*

Background: The working relationship between a therapist and a client, known as therapeutic alliance, is recognized as an important contributor to treatment change, with a stronger therapeutic alliance predicting better outcomes following therapy (Karver, Handelsman, Fields & Bickman, 2005)**.** However, the association between therapeutic alliance and treatment outcomes has been found to vary depending upon the informant source (McLeod, Southam-Gerow & Kendall, 2017). Research has only recently begun to explore the role of therapeutic alliance in treatment for children with autism. To date, only one study using a multi-informant approach to assess therapeutic alliance exists (Kerns, Collier, Lewin, & Storch, 2017), which included ratings from those directly involved in the therapy process (i.e., child, parent and therapist). Research has yet to examine the association between independent-observer and treatment-involved informants on ratings of therapeutic alliance for children with autism.

Objectives: To examine association between therapist-rated and observer-rated therapeutic alliance in cognitive behaviour therapy (CBT) for school-aged children with autism.

Methods: Data were collected from 48 children with autism (91.7% male) and their therapists (90.9% female) who participated in a 10-session CBT program to improve emotion regulation. Children were 8 to 12 years of age (*M* = 9.60 years, *SD* = 1.25) with at least average IQ. Therapist-rated and observer-rated therapeutic alliances were assessed for four sessions (two early and two late). Therapists rated the alliance on a single-item using a 7-point Likert scale (1 = Very poor; 7 = Very good) at the end of each session. The Therapy Process Observational Coding System for Child Psychotherapy-Alliance Scale (TPOCS-A; McLeod & Weisz, 2005) was used to assess alliance through independent observation. Nine items measuring key aspects of the therapeutic alliance were rated on a 6-point Likert scale (0 = Not at all; 5 = A great deal). Observers reached excellent reliability for all items (ICC = .92, $p < .001$).

Results: Spearman's correlations showed that therapist-rated alliance across early and late sessions were moderately correlated ($rs = .46$, $p = .001$) and observer-rated alliance across early and late sessions was strongly related ($rs = .65$, $p < .001$). Spearman's correlations also indicated moderate, positive relations among therapist ratings and independent-observer ratings of early and late alliance: Session 2 ($rs = .44$, $p = .003$), Session 3 ($rs = .44$, $p = .004$), Session 8 ($rs = .54$, $p < .001$), and Session 9 ($rs = .44$, $p = .003$).

Conclusions: There is a moderate degree of consistency between therapist and independent-observer ratings of the quality of early and late alliance in CBT for children with autism. Differences may in part be related to therapist ratings reflecting subjective and motivational aspects of their alliance and observer ratings not taking this into account. In addition, therapist impression of child improvement during therapy could impact ratings. Future research should explore how parent-reported and child-reported ratings of alliance are associated with observational coding, designed for children with autism, and how these factors account for variability in child outcome.

196 **211.196** Does Participation in a Peer-Mentored Physical Activity Program Increase Health-Related Fitness in College Students with Autism Spectrum Disorder?

***N. Miodrag**[1], T. Todd[2], M. Caris[3], B. Endinjok[4], R. Herrera[5], E. V. Perez[6] and M. Salazar[4], (1)Child and Adolescent Development, California State University Northridge, Northridge, CA, (2)Kinesiology, California State University, Northridge, CA, (3)California State University Northridge, Los Angeles, CA, (4)Kinesiology, California State University Northridge, Northridge, CA, (5)California State University Northridge, Northridge, CA, (6)Psychology, California State University Northridge, Northridge, CA*

Background: Many adults with ASD live sedentary lifestyles, which may contribute to an array of serious health problems including obesity, type 2 diabetes mellitus, cardiovascular disease, gastrointestinal issues, depression, and premature mortality. Individuals with ASD may have difficulty engaging in physical activity (PA) because they have poor motor skills, a lack of motivation to be physically active, and limited opportunities for exercise. Participation in regular PA is recognized as a leading indicator of health and a mediator for lifestyle-related diseases. Yet, to date, there are few PA programs designed specifically for young adults with ASD (even fewer for those in college). It is imperative to offer evidence-based PA interventions for people with ASD to help combat health-related problems and increase physical well-being.

Objectives: The purpose of this study was to examine: 1) the effects of a PA intervention on the health-related fitness (i.e., cardiorespiratory fitness, upper body muscular endurance, core abdominal muscular strength, flexibility) of college students with ASD, and 2) participant experience as a result of their participation in the fitness intervention.

Methods: IFiT (*I*nto *Fi*tness *T*ogether) is a 10-week peer-mentored individualized PA intervention designed to increase health-related fitness among college students with ASD. Data were collected during the Fall and Spring college semesters (2015-2017). A total of 34 college students with ASD (31 male, 3 female) between 18-29 years of age participated in the study. Participants were paired 1:1 with Kinesiology students (called Peer Mentors) and became dyads. Dyads met twice a week to engage in self-selected PA for a minimum of 120 minutes. At pre- and post-intervention we collected: anthropometric measures (height, weight, and waist circumference), fitness levels measured by cardiorespiratory endurance (VO^2 max), muscular endurance (sit-ups and push-ups), and flexibility (sit-and-reach). A subset of qualitative data from the larger dataset were analyzed. InVivo coding was used to generate themes from participant interviews about the IFiT experience.

Results: Twenty-six of 34 participants had Body Mass Index levels in the overweight to obese range. VO^2 max significantly increased from pre- (M = 37.49) to post-intervention (M = 42.50). Sit-and-reach scores significantly increased from pre- (M = 21.83cm) to post-intervention (M = 28.38cm). Upper body muscular endurance measured by total push-ups completed in one minute significantly increased from pre- (M = 10.29) to post-intervention (M = 13.32). There were no significant differences for core abdominal muscular strength, $p > .05$. Three main themes emerged from

participant interviews including their perceived: 1) gains in motor competence and knowledge of exercise, 2) improved overall health, and 3) sense of belonging. Participants expressed feeling "healthy and fit" and physically strong, and reported improved sleep, energy, and gastrointestinal health. Participants reported enjoying time socializing with other students with ASD and valued socializing with their Peer Mentors.

Conclusions: Regular participation in a 10-week physical activity program was beneficial to the physical health of college students with ASD. Our findings indicate that Peer Mentors offer invaluable support in helping young adults with ASD enhance their health-related fitness and social engagement.

197 **211.197** Effect of Mindfulness Training for Adolescents with Autism and Their Parents Moving to a Danish Context

***M. E. Andersen**, Department of Psychology, University of Southern Denmark, Odense M, Denmark*

Background:

High levels of distress and comorbid health difficulties have been reported for persons with autism spectrum disorder (ASD) and their parents. The development and investigation of interventions for persons with ASD is increasing, but there is still a need to expand the access to relevant interventions, and to increase the evidence base of these interventions. There is an emerging evidence suggesting beneficial effects of mindfulness-based programs for children and adolescents with ASD and their parents. MYmind is a group training for adolescents combined with parallel mindfulness training for their parents that has been developed with the cognitive characteristics of ASD in mind.

Objectives:

The study objectives were to investigate the feasibility of the MYmind program for adolescents with ASD and their parents in a Danish context and to investigate the effect of the program on individually specified areas of focus as well as on emotional and behavioral measures.

Methods:

A total of six mindfulness groups were run at two different sites including 38 adolescents with ASD and 47 parents from 37 families. Information on adolescent and parental behaviour and well-being were collected using questionnaires, at baseline, pre- and, post-training, and at 2 and 6 months follow-up. Further, continuous registrations were collected on individually specified areas of interest and general well-being. Moreover, interviews were made with adolescents and parents focusing on their experience with the training. In this presentation analyses of the repeated emotional and behavioral measures will be presented.

Results:

Of the enrolled participants 24 adolescents (63%) and 26 parents (55%) stayed in the program while 14 adolescents and 21 parents dropped out of the program. Four families dropped out before the first session and seven dropped out after taking part in only one or two sessions. The reason for withdrawing was primarily due to difficulties fitting in the training without too much stress to the family.

Comparison of pre- and post-intervention measures of parent reports on the strength and difficulties questionnaire (SDQ) showed a significant reduction in adolescent psychological distress (SDQ total: p<.000) and the impact of this distress (SDQ impact: p=.001), but not in adolescent self-report on the SDQ (SDQ total: p=.083; SDQ impact: p=.806). A significant increase in well-being was found in adolescent self-report on WHO-5 (p=.030), but no significant difference was seen on self-report of stress (Chronic stress Questionnaire, p=.457).

A significant decrease was found in parental stress (Perceived stress scale: p=.004) but no significant change was found in parental well-being (WHO-5: p=.072).

To further investigate the change over time in the whole sample results from multilevel modelling will be presented. This analyses will look at the nesting of the subject within the family and group.

Conclusions:

Challenges with recruitment and high dropout were experienced. However the results show support the existing evidence base of beneficial effects of mindfulness based intervention for adolescents with ASD and their parents.

198 **211.198** Effectiveness of ABA Parent Training in Spanish for Children with ASD

***E. Rotheram-Fuller**[1] and K. Turner[2], (1)Arizona State University, Tempe, AZ, (2)Simmons University, Boston, MA*

Background: Training in Applied Behavior Analysis for parents of children with ASD can be a critical support for both parents and their children (Bearss, Johnson, Smith, Lecavalier, & Swiezy, 2015). Parent trainings have been shown to be effective in helping improve problem behavior (Bearss et al., 2015), reducing feeding issues and parental stress (Sharp, Burrell, & Jaquess, 2014), and increasing children's skill generalization across settings (Ingersoll & Dvortcsak, 2006). Unfortunately, however, these trainings have not been extensively studied with non-English speaking populations.

Objectives: The current study seeks to examine the effectiveness in improving target problem behaviors using a 10 week parent training intervention program conducted in Spanish, for Spanish-speaking parents of school-aged children with ASD.

Methods: This study was conducted at a clinical site where 75% of families were exclusively Spanish-speaking. Families were recruited who had at least one child with ASD, aged 6-8 years old. Nine families participated in the training program (n = 11 parents overall, with two spouses attending), which consisted of 6 group sessions, followed by 4 individual sessions. Sessions focused on teaching ABA terms, strategies, and application for issues with their own children. Families completed both parent and child measures before the training began (Vineland-II, Aberrant Behavior Checklist, Parent Stress Inventory, Home-Situations Questionnaire, etc.), including a diagnostic evaluation (ADOS-2 and KBIT-2) with their child. Throughout the intervention, ABC data and parent implementation efforts were recorded, and parents repeated the self-report surveys at the end of the training.

Results: The majority of parents consistently attended sessions (84.46% attendance) and reported changes in their use of behavior strategies as a result of participation. Participating children had a variety of behavioral challenges, from non-compliance to toileting, pulling hair, or problems with outbursts at school. Each family successfully collected information on their child's behavior. Of the nine target behaviors, seven children (77.8%) showed improvements as a result of the intervention. Two parents did not report progress, as one family did not implement the intervention, and the other family discontinued participation before the end of the parent training sessions.

Conclusions: Parent training on ABA interventions was effective at reducing parent-nominated problem behavior in the vast majority of cases. Within this parent-group, there was a wide variety of parent knowledge, which was increasingly difficult for them to obtain with the language barrier. The parents who did not observe changes were those who did not choose to implement the interventions as designed. Additional resources are needed to better support non-English speaking families in learning about and implementing ABA interventions.

199 **211.199** Effectiveness of Improvisational Theater Intervention in a Community Setting in Improving Social Skills and Reducing Personal Distress

K. Paszek[1], *M. Kinnear*[1], *M. Deyski*[1], *G. Kramer*[2], *R. Ploesch*[2] *and I. Fishman*[1], *(1)SDSU Center for Autism and Developmental Disorders, San Diego State University, San Diego, CA, (2)Unscripted Learning, San Diego, CA*

Background: In the context of a community-university partnership we examined the effectiveness of an improvisational comedy theater in improving social interaction skills in teens with autism spectrum disorders (ASDs). These skills are taught during the 6-week program through various games and improvised scenarios designed to help individuals explore and laugh with each other. There is early evidence that theater interventions such as musical theater productions can improve socioemotional functioning in children with ASDs, including social awareness, social assertion, trait anxiety, and even cortisol levels (Corbett et al., 2013).

Objectives: To evaluate effectiveness of the Unscripted Learning (UL) Connections program, a community-based intervention program rooted in improv theater and comedy, on anxiety, social competence, empathy, and cognitive flexibility in teens with ASDs, using pre- and post-intervention design.

Methods: To date, thirteen youth with ASDs participating in the Connections program have been enrolled (with the new participants continuing to enroll as new Connections sessions commence). Results reported here are based on the longitudinal data from 9 adolescents who have completed the pre- and post-intervention assessments to date. Prior to the start of the program (baseline) and at the completion of the program (post-intervention) students completed the Social Skills Improvement System, Self-Report (SSIS-RS) and the Multidimensional Anxiety Scale for Children, 2nd Edition (MASC-2). Parents completed the MASC-2 parent-report, Social Responsiveness Scale, 2nd Edition (SRS-2), Behavior Rating Inventory of Executive Function, 2nd Edition (BRIEF 2), Social Communication Questionnaire, Current (SCQ), the Interpersonal Reactivity Index (IRI), and demographic forms. Follow-up assessment (at 4 months following the program completion) will be completed to test the long-term effects of the intervention.

This sample includes thirteen adolescents (10 male, 3 females) ages 13-19 years (mean = 16). Four out of thirteen participants indicated comorbid Bipolar Disorder, Global Delay, Brain Injury and Cerebral Palsy, and two of thirteen reported a diagnosis of Intellectual Disability.

Paired sample t-tests were conducted to examine the effects of the program on the SSIS-RS Social Skills, the MASC-2 Social Anxiety (measured with both self- and parent-reports), BRIEF-2 Shift and Self-Monitor subscales, SCQ Total Score, all four IRI subscales, and SRS-2 Social Awareness and Social Communication.

Results: Significant improvements post-treatment have been detected on the SSIS-RS Social Skills (effect size=0.99) and the IRI Personal Distress Subscale (effect size=0.84). Measures of Social Awareness (SRS-2), Self-Monitoring (BRIEF-2) and Shift (BRIEF-2) revealed moderate change (effect sizes=0.33-0.57). Other measures of socioemotional functioning did not reveal significant change.

Conclusions: These preliminary findings demonstrate that teens with ASDs showed some improvement in social competence, social anxiety, social responsiveness, empathy and executive function, following a 6-week improvisational theater program. This community-based improv theater intervention shows promise in improving the socioemotional functioning in teens with ASDs. These results are consistent with previously demonstrated effects of theater intervention on social awareness (e.g., Corbett et al., 2013) and further contribute to our understanding of improv theater as an effective intervention significantly impacting social skills and reducing personal distress in teens on the spectrum.

200 **211.200** Effectiveness of a Supports-Based Approach in Facilitating Peer Interactions in the Classroom Including Students on the Autism Spectrum

V. G. Vidal Velasco[1] *and L. S. DeThorne*[2], *(1)Department of Speech Language Pahtology, Los Andes University, Santiago, Chile, (2)Department of Speech, Language and Hearing Sciences, University of Western Michigan, Kalamazoo, MI*

Background: Peer interactions have been considered a major issue for students on the autism. They commonly experience challenges in developing friendships, and they have frequently been exposed to negative peer interactions (e.g., APA, 2013; Robertson, 2010). Several intervention programs have been proposed to address this issue. Most of them have taken a skills-based approach, which focuses on working toward normalizing individual skills. Despite reported effectiveness in changing individual behaviors, skills-based programs offer relatively limited evidence for successfully building peer friendships and expose concerns about social-emotional harms that have been associated with pressure to behave neurotypically (Bellini et al., 2007; DiSalvo & Oswald, 2002; Pellicano & Stears, 2011; Sibley, 2015). These Limitations have led to the development of a supports-based approach—based largely on a distributed model of communication (DeThorne et al., 2014, DeThorne et al., 2015, Hengst, 2015)—as an alternative way to facilitate peer interactions involving students on the autism spectrum (Vidal, Robertson, & DeThorne, 2018). This supports-based approach prioritizes egalitarian interactions, participation in shared activities, and flexible access to multimodal communicative resources.

Objectives: Because therapeutic programs that align with a supports-based approach are scarce, the present study uses a single-case experimental design to examine the effectiveness of a supports-based approach in promoting peer interactions in two children on the autism spectrum. For this purpose, the following research question was developed: Is there a functional relation between social supports and the increase of frequency of communicative offers between two children on the autism spectrum and one of their neurotypical classmates?

Methods: This presentation focuses on the analysis conducted within an ABAB design to measure the effectiveness on providing classroom-based social supports in increasing communicative offers observed within 2 peer dyads. Specifically, John and Ethan were a dyad of 8-9-yr-old boys observed in the context of a 3rd-grade art class. Max and Reagan were a dyad of 5-6-yr-olds observed within the context math class. Baseline phases (4-7 sessions per phase) consisted of video-recorded observations of peer interaction during classroom activities without any explicit support by the examiner. Support phases (3-7 sessions per phase) consisted in the implementation of 4 clinician strategies (i.e., direct prompt, scaffolding, behavioral interpretation, and environmental arrangement) during classroom activities. Analysis was conducted through visual

inspection.

Results: Increased communicative offers were observed during supports phases for both dyads (relative to baseline phases), which indicates a functional relation between the social support provided and the increased frequency of communicative offers. In both dyads, the average number of communicative offers doubled between baseline and social support phases. Additionally, for Max & Reagan dyad, a rise of communicative offers was observed during the second baseline phase compared to the first baseline phase, which might be indicative of a degree of generalization.

Conclusions: This is one of the first studies to provide experimental evidence for a supports-based approach to peer interaction in students on the autism spectrum. Generalizations results are encouraging in showing how this approach has impact on quality of life indicators such as friendship.

201 **211.201** Effects of Transdiagnostic Versus ASD-Only Therapy Groups for Children with ASD

M. Reid[1], *A. A. Pallathra*[2], *B. Rich*[1] *and M. K. Alvord*[3], *(1)Catholic University of America, Washington, DC, (2)Department of Psychiatry, Catholic University of America, Washington, DC, (3)Alvord, Baker & Associates. LLC, Rockville, MD*

Background: Transdiagnostic approaches to social competence group interventions may best benefit children with ASD so that they learn to interact with children with disorders other than ASD. Weiss (2014) suggested that a transdiagnostic approach may be most efficacious for children with ASD because a disorder-specific approach may miss the underlying mechanisms that lead to co-occurring problems. Clarifying this issue may help inform both treatment and academic decisions, as parents and school administrators must determine whether a child with ASD should be placed in 'mainstream' or ASD-specific classrooms.
Objectives: The current study examines whether therapeutic effects are similar for a child with ASD whether they are in an ASD-only group or a transdiagnostic therapy group.

Methods: A sample of 45 children ages 7-12 years were enrolled in the Resilience Builder Program® (RBP) intervention, a 14-week, manualized, group intervention for children with social competence and self-regulation challenges (Alvord, Zucker, & Grados, 2011). Treatment was completed at a private practice in Maryland. RBP is a cognitive behavior therapy (CBT) group program designed for children with social deficits. Two types of groups were conducted: a 'mainstream' group wherein a child with ASD was integrated into a group with children with diagnoses other than ASD, including social anxiety and ADHD, or a group comprised of only children with ASD. Group assignment was based on severity of social deficits and ASD symptoms. 24 children with ASD were enrolled in 'mainstream' groups (mean age = 9.83 ± 1.93 years; 75% male; 79% Caucasian) while 21 children with ASD were enrolled in ASD-only groups (mean age = 9.24 ± 1.58 years; 81% male; 62% Caucasian). Parents completed the Behavior Assessment System for Children (BASC-2; Reynolds & Kamphaus, 2004) pre- and post-therapy to evaluate treatment impact on social, emotional, and behavioral functioning. Change scores of select subscales of the BASC-2 from pre- to post-therapy were calculated to compare groups on treatment efficacy.

Results: Groups were not significantly different based on gender, race, age, or family income. Independent samples t-tests indicated no significant difference in change scores between groups on multiple domains, including Social Skills, $t(29) = -.70$, $p = .224$, Adaptive Skills, $t(29) = -.46$, $p = .088$, Developmental Social Disorders, $t(29) = 1.02$, $p = .282$, Internalizing Problems $t(29) = -.44$, $p = .444$, and Externalizing Problems, $t(29) = -.67$, $p = .461$.

Conclusions: Change scores did not differ between the groups on multiple domains of functioning, including social skills, affect, and behavior. The results suggest that the efficacy of a resilience-based CBT group therapy may be comparable regardless of whether children with ASD are enrolled in transdiagnostic versus ASD-specific groups. This research may speak to the idea that it may be more beneficial to match children with ASD based on skill-level as opposed to diagnosis only.

202 **211.202** Efficacy of Synergized Cognitive-Physical Training for Children with Inattention

M. R. Gerdes[1], *B. G. Jurigova*[1], *A. J. Simon*[1], *D. R. Mittermaier*[1], *J. Sandling*[1], *A. Gazzaley*[1], *J. Anguera*[1,2] *and E. J. Marco*[1,3], *(1)Neurology, University of California San Francisco, San Francisco, CA, (2)Psychiatry, University of California San Francisco, San Francisco, CA, (3)Cortica Healthcare, San Diego, CA*

Background: Children with issues of attention have difficulties in their everyday life and school function due to deficiencies in these abilities. Cognitive training and physical exercise have both been shown to improve attention, providing an alternative approach to prescribed medications. Here we posit that a synergistic training platform for children across the inattention spectrum, including children with ASD, may lead to improved cognitive control abilities.
Objectives: To use a custom-designed, motion-capture, video game-based intervention (pediatric body-brain trainer (pediBBT)) adapted for school-aged children and deployed at a local elementary school to evidence potential improvements in cognitive control. Our first aim was to determine whether pediBBT is feasible in a school based setting. Aim 2 was to determine if this platform improves cognitive control abilities in children with and without clinically significant inattention as measured behaviorally and neurally via electroencephalography (EEG).

Methods: Eight children (7 boys), aged 7-12 years, underwent 24 pediBBT sessions across eight weeks. 7 out of 8 completed all pre and post assessments. PediBBT consists of three modules aimed at training attention, working memory, and goal management in which subjects respond to stimuli by reaching, squatting, or running. ADHD symptoms and cognitive abilities, specifically sustained attention, response inhibition, and working memory, were assessed prior to and following intervention using parent report (Vanderbilt ADHD Diagnostic Parent Rating Scale) and direct assessment (Test of Variables of Attention (TOVA), Attend-Ignore Distractor (AID)). Additionally, we assessed for changes in midline frontal theta, an EEG marker associated with focused attention processing, using a custom designed perceptual discrimination task.

Results: Regarding Aim 1 (feasibility), 100% of children completed all 24 sessions. In response to the question: "Overall, how would you rate you/your child's experience with pediBBT?" on a scale of 1-100, the mean score was 87, with a range of 70-100. On parent report measures of inattention, 3 out of 8 participants scored in the clinically significant range for ADHD at baseline -- 1 Inattentive, 1 Hyperactive, and 1 Combined type. Out of the 3 participants with parent-report based ADHD, 2 participants no longer meet criteria after pediBBT intervention. Direct assessment using TOVA showed statistically significant improvement in response time in 6 out of 7 children ($p=.027$) and response time variability ($p=.01$) in all 7 children. On our test of working memory, all 3 of the children with issues of inattention showed improvement. Our neural analyses

using EEG event related spectral analysis showed an increase of midline frontal theta across the cohort.

Conclusions: These findings provide initial evidence that an eight week, in-school, synergistic cognitive-physical training is feasible in children 7-12 years of age. Furthermore, it may improve cognitive abilities in children with attention challenges. We continue to enroll participants and analyze data and will be able to present outcomes of a larger sample in May of 2019. We also plan to recruit control groups with cognitive only and physical only training to determine the most effective outcome.

203 **211.203** Emotion Regulation and Empathy in an Adult Social Skills Intervention

***E. F. Ferguson**, J. A. Ko, E. McGarry, S. J. Cohen, A. R. Miller and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Empathy and emotion regulation (ER) are critical contributors to success in social and vocational settings for adults with autism spectrum disorder (ASD). Individuals with ASD often have difficulties both reading and regulating emotional states, which may interfere with their ability to react appropriately in social situations (Mazefsky, Pelphrey, & Dahl, 2012; Mazefsky & White, 2014). It is believed that impairments in ER may relate to challenges with perspective-taking, which is key to empathy (Baron-Cohen & Wheelwright, 2004). Empathy and ER are two treatment considerations and potential targets that may help to optimize outcomes in psychosocial interventions for adults with ASD.
Objectives: To examine baseline levels and resulting changes in empathy and emotion regulation endorsements in the context of the Social Tools and Rules for Transitions (START) Program for Young Adults with ASD.

Methods: Twenty-eight young adults with ASD and fluent language use (18-25 years, *M* = 20.72) participated in a young adult version of the START program, an experiential social competence and motivation intervention (Vernon, Miller, Ko, Barrett, McGarry, 2017). Participants were randomly assigned to immediate treatment (*n* = 12) or waitlist control (*n* = 16) groups for 20 weeks. The peer-mediated START sessions were facilitated by undergraduates and consisted of individual check-in/check-out meetings, free socializing periods, interactive topic discussions (e.g., conversation skills, relationships, social momentum, and employment), and structured social games. Participants and mentors also went on weekly social community outings. Participants completed self-report measures at baseline and post-intervention/post-waitlist, including the Empathy Quotient (EQ) and BASC-3. Higher scores on the EQ are associated with greater levels of empathy, while higher scores on the Emotional Symptoms Index (ESI) composite of the BASC-3 are associated with greater internal distress and emotional disturbance.

Results: For all participants, there was a significant negative correlation between the EQ and the BASC-3 ESI at baseline ($r(26) = -.543$, $p = .003$; Figure 1). For the treatment group, a linear regression revealed that baseline ESI scores predicted change in empathy scores from baseline to post-intervention ($r^2 = .595$, $F(1,9) = 13.25$, $p = .005$; Figure 2). A repeated measures ANOVA yielded a significant *Group x Time* interaction for the EQ, $F(1,23) = 5.41$, $p = .029$. The BASC-3 ESI scores did not change significantly from baseline to post-intervention.

Conclusions: Results indicate significant improvements in empathy in the context of the START socialization program. Findings also indicate that individuals with fewer symptoms of emotional dysregulation at baseline report higher empathy, suggesting a possible relationship between emotional control and the ability to infer and relate to the emotional states of others. Greater ER difficulties at baseline were linked to greater improvements in empathy scores. This finding suggests that ER profiles may be one predictor of individual difference in response to psychosocial interventions. ER may be addressed indirectly through practice enhancing emotional language in the START intervention (Mazefsky & White, 2014). Future research will explore ER as an important treatment target that underlies increased social understanding and relatedness for adults with ASD.

204 **211.204** Establishing Best Practices in the Implementation and Evaluation of Novel Employment Programs for High School Students with ASD: A Case Study

***B. Di Rezze**[1], I. O'Connor[2], G. B. Hall[3], R. Brennan[4], S. Georgiades[1], E. Badone[5], A. DiFazio[6], M. Maric[7], A. N. Cantelmi-Cicchi[8], C. Carroll[9], K. St. Pierre[10], K. Shanmugarajah[1], K. Fish[1] and T. Bennett[11], (1)McMaster University, Hamilton, ON, Canada, (2)McMaster Universtiy-Offord Centre, Dundas, ON, Canada, (3)Psychology, Neuroscience & Behaviour, McMaster University, Hamilton, ON, Canada, (4)Woodview Mental Health and Autism Services, Burlington, ON, Canada, (5)Anthropology, McMaster University, Hamilton, ON, Canada, (6)Hamilton-Wentworth District School Board, Hamilton, ON, Canada, (7)Student Support Services, Hamilton-Wentworth Catholiic District School Board, Hamilton, ON, Canada, (8)Student Support Services, Hamilton-Wentworth Catholic District School Board, Hamilton, ON, Canada, (9)Autism Nova Scotia, Halifax, NS, Canada, (10)Hamilton Health Sciences, Hamilton, ON, Canada, (11)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA*

Background:
Employment initiatives for youth with autism spectrum disorder (ASD) have increased within clinical, educational and community settings. Rigorous implementation and evaluation procedures are essential for advancing evidence-based research on effective vocational training and supports for individuals with ASD. Knowing how to demonstrate fidelity in program delivery, specifically with job supports, and what outcomes are identified to examine participant progress are critical but underdeveloped in research. This study describes the measurement model, outcomes, and lessons learned from the Job-Train Program (JTP), a community-based employment program that involved paid-summer employment for high school students with ASD on a university campus.

Objectives:

(1) Examine the implementation of job supports within JTP.

(2) Evaluate student participant outcomes within JTP.

Methods:

Examining employment supports involved procedures to prepare job coaches and worksites for their role with JTP participants. Job coach training and ongoing online support were provided through a manualized job coaching program. Fidelity evaluation of coaches supporting participants on job placements was measured using a fidelity checklist of 14 behaviours to evaluate 5-10 minute videos from the worksite. Fidelity checklists were completed twice for job coaches, at the start and towards the end of work placements.

Student primary outcome measures were collected to: examine performance and satisfaction in employment-related issues measured through the Canadian Occupational Performance Measure; and evaluate emotional and behavioral problems, measured by the Child Behavior Checklist. Secondary outcomes included areas of work readiness and everyday functioning of participants within JTP. Weekly observational data of

participants (over 5 weeks) were rated on a 5-point scale by Job Coaches, regarding job performance, conversation skills and safety awareness. Qualitative outcome data were collected from students, parents, and job coaches.

Results:

A total of 12 credit-bearing high school students with ASD participated in JTP (age: 16.2 [0.8] years; 92% males). Secondary diagnoses included anxiety (33%) and ADHD (42%). Campus job placements included roles within the library, office settings at various departments and research centers, campus mailroom and residential suites. Students were supported by three Job Coaches. Fidelity checklist ratings of multiple videos across all Job Coaches included an average score of 45.2% early on in job placement, and 90.5% towards the end. Qualitative feedback was provided by job coaches on job placement videos and the fidelity checklist (to be analyzed and presented at conference). Primary and secondary outcomes are currently being collected based on pre-post measures and will be analyzed using parametric and non-parametric methods (to be analyzed and presented at conference). Average participant observational data in the workplace demonstrated positive improvements from time 1 to time 5 for areas of job performance (2.7 to 4.5), conversation skills (2.9 to 4.1), and safety awareness (3.2 to 4.3).

Conclusions:

Evaluation of fidelity checklist outcomes demonstrated gradual improvement in Job Coaches' implementation of key behaviours when comparing ratings at two time points over job placement. JTP students improved in their job and conversation skills and safety awareness on their job placements. Quantitative and qualitative outcomes will be analyzed and reported in conference presentation.

205 **211.205** Examining Children with Autism Spectrum Disorder's Negativity/Lability: Teaching Emotion Regulation Strategies through the Stress and Anger Management Program (STAMP)

R. S. Factor[1,2], *D. Swain*[1,2], *L. Antezana*[1,2], *A. Muskett*[1,2], *A. J. Gatto*[3], *S. R. Radtke*[1] *and A. Scarpa*[2,3], *(1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech Center for Autism Research, Blacksburg, VA, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA*

Background: Emotion Regulation (ER) is critical in children's social and emotional development and is often delayed or impaired in children with Autism Spectrum Disorder (ASD). Poor ER has been associated with increased anxiety, irritability, and poor self-regulation, leading to behavioral outbursts and potentially more restricted and repetitive behaviors. The Stress and Anger Management Program (STAMP) adapts Cognitive Behavioral Therapy (CBT) for younger children with ASD (4-7 years; preschool/kindergarten developmental level) and adds a parent training component. STAMP teaches children ER strategies, specifically what they can do to manage their emotions, and views parents as co-facilitators. A pilot study indicated group level differences (STAMP vs. Waitlist control) in ER measured post-treatment.

Objectives: The current study expands the original sample (from 11 to 23 participants) to test if STAMP decreases negative affect expression in young children with ASD compared to a Waitlist group in order to provide stronger evidence of the efficacy of STAMP in a Randomized Control Trial (RCT) design.

Methods: Twenty-three parent/child dyads (19 boys; 100% Caucasian) ranging from 4 to 7 years old (M = 5.46; SD = 1.01) participated in STAMP groups. Each dyad was randomly assigned to the Treatment (TX; i.e., STAMP; n = 12) or Waitlist control (WL; n = 11) group. All completed more than 50% of sessions. Eleven families participated in the original pilot study (n = 5 TX, 6 WL), and 12 families were added post-pilot (n = 6 per group). To qualify, children were required to meet criteria for ASD on the ADOS or ADOS-2, communicate verbally, understand basic verbal instructions (e.g., sit here), have parent-reported difficulties managing anger or anxiety, and be able to tolerate a group setting. Parents completed the Emotion Regulation Checklist (ERC), which assesses two dimensions of ER: regulation (ER) and negativity (Lability/Negativity; L/N). The L/N subscale targets expression of negative emotions, inflexibility, and mood, which is the focus of the STAMP intervention. The ER subscale was not examined.

Results: Paired samples t-test for TX revealed a significant difference in L/N for Time 1 vs. Time 2, $t(9) = 2.45$, $p = .03$, with decreased L/N at Time 2. For WL, there was no significant difference in L/N for Time 1 vs. Time 2, $t(7) = 1.02$, $p = .34$. TX gains for all participants revealed a significant difference in L/N pre-treatment (Time 1 for Treatment group and Time 2 for WL combined; M = 39.28, SD = 5.34) to post-treatment (Time 2 for TX and Time 3 for WL combined; M= 35.11, SD = 4.46), $t(17) = 3.26$, $p < .01$, Cohen's d = .77, suggesting a medium effect size.

Conclusions: Results support previous findings regarding benefits of STAMP in improving ER in young children with ASD. This study provides further support for using CBT with young children's ER skills. Improvements in children's ER skills may be important in the development of social relationships as well as reductions in psychopathology and therefore, it is critical that future research continue to explore the most effective way to elicit these skills.

206 **211.206** Examining Use of CBT Strategies for Anxiety: A Pilot Study with Adolescents with ASD and Intellectual Disability

A. T. Meyer[1], *R. E. Boles*[2], *K. Pickard*[1], *J. Reaven*[3] *and A. Blakeley-Smith*[4], *(1)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (2)University of Colorado School of Medicine, Aurora, CO, (3)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (4)Univ. of Colo. Denver-JFK Partners, Aurora, CO*

Background: Cognitive Behavioral Therapy (CBT) has been used to address anxiety symptoms in youth with ASD with promising results (Reaven et al., 2012, 2018; Wood et al., 2009). However, few treatment programs have specifically used CBT to reduce anxiety in individuals with ASD *and* Intellectual Disability (ID; Rosen et al., 2016). The extent to which individuals with ASD and ID are able to learn and use CBT strategies is unclear, particularly given of the heterogeneity of this population. A pilot intervention assessing the initial feasibility, acceptability and efficacy of CBT for adolescents with ASD, ID, and anxiety was completed (Blakeley-Smith et al., submitted INSAR 2019). The purpose of this study is to evaluate the attainment of CBT skills in a subsample of this study.

Objectives: To determine whether adolescents with ASD, ID, and anxiety are able to develop core skills and strategies from a CBT program for anxiety as documented through individualized Goal Attainment Scaling (GAS; Ruble et al., 2013) and evaluate anxiety and mood in this subsample.

Methods: Seven adolescents (Mage=16.60 years, SD=2.13, range=12-18 years) with ASD, ID, and anxiety participated in a larger pilot study evaluating an adaptation of Facing Your Fears (Reaven et al., 2011), a 14-week group CBT program to treat anxiety. All participants completed treatment and met criteria for ID: Full Scale IQ (M=64.00, SD=9.17; range=54-79) and adaptive behavior scores (M=57.29, SD=20.48) and anxiety based on parent report on either the Screen for Childhood Anxiety and Related Disorders (SCARED; Birmaher et al.,1999) or the Anxiety, Depression, and Mood Scale (ADAMS; Esbensen et al., 2003).

GAS goals and ratings were determined for each participant across 5 treatment domains: somatic management, emotion identification and regulation, cognitive strategies, exposure practice, and behavior management. Ratings were based on a parent interview conducted pre- and post-treatment and direct observation based on recommended GAS procedures (Ruble et al., 2013). Two to five goals per domain were created for each participant with total number of goals ranging from 11-17. See Table 1 for scoring information.

Results: Results from GAS scores indicated variability in use of CBT skills within participants and across subdomains after participating in treatment (See Table 2). In addition, dependent samples t-test indicated significant differences on the ADAMS (pre-treatment=42.00, SD=11.66; post-treatment=26.14, SD=8.61; $t(6)=3.87$, $p=.008$), suggesting decreased mood and anxiety symptoms.

Conclusions: GAS scoring showed that all participants made gains in CBT strategy use following participation in modified CBT program for anxiety. Of note, six of the seven participants exhibited 'expected' or 'greater than expected' use of cognitive strategies. This is noteworthy as cognitive strategies are not well researched or addressed in this underserved population (Rosen et al., 2016). Decreases were also noted in anxiety and mood symptoms, although it is unclear to what extent this reduction is tied to increased strategy use. Further research is needed to examine the active ingredients of treatment and if GAS ratings can best capture teens' use of these skills. Limitations include a small sample size and lack of independent raters for the GAS scores.

207 **211.207** Examining the Impact of Physical Activity on Sleep Quality in Children with Autism through Melatonin-Mediated Model: A RCT

A. C. Y. Tse[1], *P. H. Lee*[2], *J. Zhang*[3] *and E. W. H. Lai*[4], *(1)Department of Health and Physical Education, The Education University of Hong Kong, Hong Kong, Hong Kong, (2)School of Nursing, Hong Kong Polytechnic University, Hong Kong, Hong Kong, (3)Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong, (4)Department of Psychiatry, Castle Peak Hospirtal, Hong Kong, Hong Kong*

Background: Sleep disturbance is commonly found in children with autism spectrum disorder (ASD) and is often accompanied by family distress. Disturbed sleep may exacerbate the core symptoms of ASD, including stereotypic behaviors, social interactions, and health problems. Therefore, it is important to develop effective intervention strategies to ameliorate sleep disturbance in children with ASD. Traditionally, behavioral interventions and supplemental melatonin medication are used to improve sleep quality. However, the poor sustainability of behavioral intervention effects and use of other medications (e.g., antidepressants and stimulants) that metabolize melatonin may degrade the effectiveness of these interventions. Alternatively, previous research supported physical activity as an effective intervention for treating sleep disturbance in typically developing (TD) children. It is therefore natural to extend the study to examine whether such intervention is also effective in children with ASD.

Objectives: In the present study, we aimed to investigate whether physical activity is an effective intervention to improve sleep quality for children with ASD. Moreover, we also investigated how physical activity impacts on sleep in children with ASD through a melatonin-mediated mechanism model. According to this model, it is suggested that physical activity could affect circadian rhythm by altering melatonin levels. Melatonin levels are generally lower in children with ASD than in their typically developing counterparts and supplemental melatonin medication is often used to treat sleep disturbance in this population.

Methods: We conducted a parallel-group randomized controlled trial of 28 child participants with ASD that compared a jogging intervention group and a control group receiving standard care. We have monitored the changes of their sleep quality as depicted by four sleep parameters (sleep onset latency, sleep efficiency, wake after sleep onset and sleep duration) through objective actigraphic assessment and parental sleep logs. To measure melatonin level, all participants were instructed to collect a 24-h urine sample. 6-sulfatoxymelatonin, a creatinine-adjusted morning urinary melatonin representative of the participant's melatonin levels, were measured from the sample. All assessments were carried out before the intervention (T1) and immediately after the 12 weeks of physical activity or regular treatment (T2).

Results: The present study revealed a significant improvement between T1 and T2 in sleep efficiency, sleep onset latency and sleep duration in the intervention group (all $ps < .05$) but not in the control group (all $ps > .05$). More significantly, there was a significant increase of the urinary 6-sulfatoxymelatonin (ng/ml) ($p < .05$) between T1 and T2 in the intervention group (4.65±5.27 vs 8.09±5.24) but not in the control group (3.31±4.87 vs 4.09±3.38) ($p > .05$).

Conclusions: The findings of this proposed study provided an insight to the mechanism by which physical activity impacts on sleep in children with ASD, which may ultimately lead to the design of an effective intervention to improve the sleep quality of children with ASD.

208 **211.208** Exploring New Outcome Measures to Assess Effectiveness of the PEERS® Social Skills Intervention

N. L. Matthews[1], *C. Mortensen*[1], *S. N. Rife*[1], *B. Orr*[1], *K. Warriner*[2], *M. DeCarlo*[1] *and C. J. Smith*[3], *(1)Southwest Autism Research and Resource Center, Phoenix, AZ, (2)Comprehensive Behavioral Programs, Southwest Autism Research and Resource Center, Phoenix, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Most studies that indicate effectiveness of PEERS®, a manualized social skills intervention for adolescents with autism (ASD; Laugeson & Frankel, 2010), rely on parent-, adolescent-, and/or teacher-report questionnaires to document outcomes. This may introduce bias because participants are not blind to their study group.

Objectives: To utilize structured conversation probes coded by raters blind to study group and time point to compare change in (a) adherence to the rules for two-way conversations taught during PEERS, and (b) social likeability among participants who were randomly assigned to complete PEERS, a peer-mediated model of PEERS (PMP), or a delayed treatment control (DTC) group.

Methods: Participants were 34 adolescents with ASD (age $M = 15.23$, $SD = 1.18$; 82% male) and 16 typically developing (TD) peer mentors (age $M = 15.50$, $SD = 1.27$; 44% male). Participants with ASD met criteria for autism/autism spectrum on the ADOS-2 and had an overall or verbal IQ ≥ 70. PEERS was delivered as manualized to the PEERS group. It was delivered identically to participants in PMP, with the exception of the inclusion of TD peer mentors. DTC was assessed at 3 time points over 9 months.

Participants (ASD and TD) completed a videotaped 10-minute structured conversation probe with a novel research assistant pre- and post-intervention. Participants with ASD completed additional probes at 4-month and 1-year follow-ups. It was not possible to collect 1-year probes from DTC participants because they had already started treatment.

Adherence to 16 rules for two-way conversations was coded by trained raters using whole and partial interval recording. Higher scores indicated

greater adherence (second rater coded 43%: ICC = .92). To assess social likeability, four novice research assistants watched each video and responded to the statement "What is the likelihood that similar-aged teenagers would enjoy socializing with the participant" using a Likert scale ranging from 1-unlikely to 10-likely. Scores were averaged across raters (ICC = .88).

Results: There was a significant group by time interaction for adherence (Figure 1; $F(4, 62) = 2.95$, $p = .03$) and the group by time interaction for social likeability approached significance (Figure 2; $F(4, 62) = 2.42$, $p = .06$). Bonferroni post-hoc comparisons indicated that PMP demonstrated greater adherence at immediate and 4-month follow-ups (Times 2 and 3) compared to pre-intervention ($ps = .01$) and had higher social likeability scores at 4-month follow-up compared to pre-intervention ($p = .02$). Results from 1-year follow-up (Time 4) data indicated a significant increase from pre-intervention in adherence ($p = .01$) and social likeability ($p < .001$) in the PMP group. Adherence and social likeability in PEERS and DTC groups did not differ across time points.

Conclusions: Findings suggest that adolescents in PMP increased adherence to rules for two-way conversations, and that treatment gains were maintained at 4-month and 1-year follow-ups. Treatment gains in adherence were partially corroborated by gains in social likeability. Findings are consistent with previously reported results from adolescent- and parent-report questionnaires from the same sample that indicated a modest advantage for PMP relative to PEERS (blinded).

209 **211.209** Exploring the Factor Structure of Child- and Caregiver-Directed Treatment Strategy Delivery in an Individualized Mental Health Intervention for ASD (AIM HI)

K. Martinez[1], *E. Hurwich-Reiss*[2], *T. Lind*[2], *C. Chlebowski*[3] *and L. Brookman-Frazee*[4,5], *(1)Clinical Psychology, San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, (2)University of California, San Diego, La Jolla, CA, (3)National Institute of Mental Health, Bethesda, MD, (4)Psychiatry, University of California, San Diego, San Diego, CA, (5)Child and Adolescent Services Research Center, San Diego, CA*

Background: AIMHI ("*An Individualized Mental Health Intervention for ASD*"), a parent mediated and child-focused behavioral intervention for children 5-13 years of age with ASD, has been shown to have a long-lasting impact in reducing challenging behaviors when delivered by therapists in publicly-funded mental health (MH) settings (Brookman-Frazee et al., under review). AIMHI intervention strategies are theoretically conceptualized into two broad categories (*Active Teaching* & *Within Session Elements*); however, statistical exploration of the factor structure of these treatment elements has not been conducted.

Objectives: The current study aimed to explore the factor structure of therapists' delivery of child- and parent-directed AIMHI intervention strategies during therapy sessions.

Methods: Data were drawn from a large-scale effectiveness trial of AIMHI; in the intervention condition therapists received training in AIMHI and delivered the intervention to their client for 6 months. Therapists' use of child- and parent-directed AIMHI strategy delivery was evaluated using observational coding of therapy sessions. Participants included 143 therapist-child dyads in the intervention condition of the trial. The child sample (n=143) consisted of 83% males, with a mean age of 9.05 (SD=2.5). Therapists (n=126) were 34 years of age (SD=8.30), and ranged in experience (0-55 years). Seventy-two percent of the children and fifty-nine percent of the therapists were from an ethnic minority background. The number of coded sessions per child was 8.06 sessions (SD=3.2). Multilevel exploratory factor analyses (MEFA) with geomin rotation were run on Mplus to explore the factor structure of child-directed and parent-directed therapist strategies in the delivery of AIMHI.

Results: The Root Mean Square Error of Approximation (RMSEA) and the Comparative Fit Index (CFI) were used to evaluate model fit, with an RMSEA of ≤ 0.08 and a CFI > 0.95 indicative of good model fit. For the child-directed strategies, MEFA indicated preference for a two-factor model with unrestricted within-level covariance. The two-factor model demonstrated excellent fit $X^2(19) = 97.55$, $p < .001$; CFI = .96., RMSEA = .02. Six items loaded onto the first factor, termed Engagement Strategies, while three items loaded onto the second factor, termed Active Teaching Strategies (see Table 1). For the parent-directed therapist strategies, a one-factor model with unrestricted covariance was revealed. Model fit was excellent $X^2(20) = 36.24$, $p < .05$; CFI = .99, RMSEA = .00. The factor included 8 items. See Table 1 for more details.

Conclusions: Findings based on MEFA suggest that AIMHI child-directed strategies are best characterized by a two-factor model, whereas a unidimensional model best captures parent directed strategies. These results confirm the importance of using active teaching strategies (modeling, behavioral rehearsal, feedback and reinforcement) to teach child and parent skills and highlight the importance of using specific engagement strategies in MH delivery for an ASD population. Next steps will include confirming the factor structure of child- and parent-directed strategy delivery in AIMHI using multilevel confirmatory factor analyses. Long-term, these factors might be used to understand which factors best predict AIMHI treatment response as well as to understand which child and parent characteristics best predict strategy delivery.

210 **211.210** Feasibility/Pilot Study of a School-Based Adaptive Intervention for Children with HFASD

S. L. Andrews*, A. J. Booth, M. Thomeer, C. Lopata, J. D. Rodgers and S. L. Brennan, Institute for Autism Research, Canisius College, Buffalo, NY*

Background:

The core deficits of students with high-functioning autism spectrum disorder (HFASD) negatively affect social and academic performance (Kasari et al., 2016). Problems with skill generalization from clinic-based interventions have prompted calls for development and testing of social skills interventions within school environments (Kasari et al., 2012; Kretzmann et al., 2015). Adaptive school-based social interventions may be a viable option for students with HFASD, as they can be tailored to the student's needs, and the intensity can be adjusted based on treatment response (Reichow & Barton, 2014). However, no studies have examined the feasibility of a school-based adaptive social skills intervention for students with HFASD.

Objectives:

This study examined the feasibility and initial efficacy of an adaptive school-based social intervention for 1st through 5th grade students with HFASD.

Methods:

Participants. Thirteen children, aged 6-11 years with HFASD, were included. Specific inclusion criteria were: (1) short form IQ >70 (one major index score >80); (2) expressive or receptive language score >75; and (3) diagnostic confirmation using an ASD diagnostic interview, screening measure,

and/or clinical consensus.

Measures. Skillstreaming Knowledge Assessment (SKA); Adapted Skillstreaming Checklist (ASC); Social Responsiveness Scale, 2nd Ed., (SRS-2); Clinical Global Impression scale (CGI)

Procedures. After baseline testing, all participants received a low intensity social skills intervention (LI-SSI; 1x/30 min per week social skills group [SSG]) for 10 weeks. Following 10 weeks of LI-SSI, responders to the LI-SSI continued to receive the LI-SSI. Non-responders were randomly re-allocated to one of two intensified SSI conditions including a Moderate Intensity SSI (MI-SSI; 2x/30 min per week SSG) or a High Intensity SSI (HI-SSI; 2x/30 min per week SSG plus behavioral reinforcement system) for the remaining eight weeks of intervention. Rating scales, a global impairment rating of clinical progress, and child testing of social skills knowledge were completed pre- and post-treatment.

Results:

Feasibility was supported in high levels of treatment fidelity (SSG component >93%) and parent and SSG facilitator satisfaction. Satisfaction ratings averaged 61.5 out of 70 points for parents and 62.3 out of 70 points for SSG facilitators. Pre-post comparisons indicated a significant decrease in parent (SRS-2 p=.041, d=-.58) and teacher (SRS-2 p=.011, d=-.70) rated ASD symptoms, an increase in parent (ASC p=.002, d=1.05) and teacher (ASC p=.041, d=.59) rated social skills, and a decrease in parent (CGI p < .001, d=-1.22) and teacher (CGI p < .001, d =-1.49) global impairment ratings. Child testing showed an overall increase in number of social skills known (SKA p=.001, d=.91) and knowledge of the steps for the skills (SKA p=.002, d =.76)

Conclusions:

Results suggest the intervention can be conducted with a high degree of fidelity, parents/school staff find it acceptable, and participation is associated with significant symptom and skills improvements. These findings are especially promising as the effect sizes on some of the parent, teacher, and child measures were large. However, the small sample limits the ability to test the adaptive component of the intervention. Future work using a fully-powered sequential, multiple assignment, randomized trial (SMART) design (Nahum-Shani et al., 2012) is needed.

211 **211.211** How Do We Care for Children with Autism Spektrum Disorder When Coming for a Procedure Requiring Anesthesia?

I. Gimbler Berglund[1], *K. Huus*[2], *K. Enskär*[2], *B. Møller Christensen*[3], *M. Faresjö*[4] *and B. Jacobsson*[4], *(1)Department of Nursing, Jönköping University, Jönköping, Sweden, (2)Nursing, School of Health and Welfare, Jönköping University, Jönköping, Sweden, (3)department of natural Sciences and Biomedicine, Jönköping University, Jönköping, Sweden, (4)Natural sciences, School of Health and Welfare, Jönköping University, Jönköping, Sweden*

Background: Children with Autism Spectrum Disorder (ASD) have problems with communication and social interaction. They are also dependent on routines and sensitive to sensory stimuli. Due to the problem's children with ASD have it can be a challenge for the Health Care Professionals (HCP) to establish a rapport with the child. This can lead to an uncooperative behavior during anesthesia induction which might result in the child being physically restrained for anesthesia induction. Such a traumatic event can exaggerate a child's anxiety for the next anesthesia induction. Children with ASD pose a challenge for the HCPs tasked to provide the child with care. Preparing both the child and the environment to suit the child's needs may decrease anxiety in children with ASD. In order to achieve this, the use of family-centered care and evidence-based guidelines would be beneficial.

Objectives: The aim of this study was to describe current ways to prepare and care for children with ASD for procedures and oral health care with sedation or general anesthesia.

Methods: A web-based questionnaire was distributed to the head of Swedish dental departments of pediatric dentistry and to anesthesia departments in Sweden. The questionnaire investigated the existence of guidelines for preparing and care of children with ASD for procedures and dental treatment under sedation or general anesthesia. Descriptive statistics and content analyses was used to analyze the answers from the questionnaires.

Results: Six pediatric dental departments out of 37 had guidelines on how to prepare children with ASD for sedation or general anesthesia and 7 out of 68 anesthesia departments caring for children with ASD had guidelines on how to prepare and care for these children. The guidelines in the pediatric dental departments consisted of comprehensive planning together with the parents for the entire health care visit to suit the individual child. Many departments left the preparation of the child to the anesthesia department when it came to anesthesia for dental care for these children. From the anesthesia departments three categories emerged, those were: "care with specific consideration for children with ASD", "lacking the necessary conditions," and "no extra consideration needed". These three categories span a continuum in the care from a care that was based on family-centered care tailored for the specific child to actually have as a routine to physical restraining a child for an anesthesia induction.

Conclusions: Considering the lack of guidelines for preparation of children with ASD for procedures and dental treatment in sedation or general anesthesia, there is a necessity for evidence-based, guidelines that are specifically designed to meet the needs of children with ASD in order to give high quality care and avoid a traumatizing experience for the children.

212 **211.212** Human-Companion Animal Interaction and Parent Stress in Families of Children with Autism

G. K. Carlisle[1], *R. A. Johnson*[2], *A. Hutchison*[1], *T. Brosi*[3] *and E. Rife*[4], *(1)College of Veterinary Medicine, University of Missouri, Columbia, MO, (2)College of Veterinary Medicine and Sinclair School of Nursing, University of Missouri, Columbia, MO, (3)University of Missouri, Columbia, MO, (4)Veterinary Medicine, University of Missouri, Columbia, MO*

Background:

Extant literature on interaction of children with Autism Spectrum Disorder (ASD) and Companion Animals (CAs) found animals to be an alternative/adjunctive method of alleviating social skills deficits and anxiety. Parents report benefits of companionship, unconditional love, happiness and learning responsibility from animal care-taking. In one study, lower stress was associated with living with CAs for parents of children with ASD.

Objectives:

This study aimed to examine CA ownership patterns in families of children with ASD, and to identify potential health and safety risks to the CAs. We also explored the relationship between CA ownership and parental stress among families of children with ASD. Additionally, we sought to

assess characteristics of the relationship between children with ASD and the family CA, along with parental perceptions of potential benefits and barriers of human-CA interaction.

Methods:

Participants (N=747) were recruited via the Interactive Autism Network (IAN) Research Database at the Kennedy Krieger Institute, Baltimore. Instruments included a demographic survey, Parenting Stress Index Short Form, Animal Ownership for Families of Children with ASD Scale, Lexington Attachment to Pets Scale and the Companion Animal Bonding Scale. Participants who access the IAN were invited to complete the instruments anonymously online.

Results:

Preliminary descriptive findings revealed the following information: Parent age (Mean=44.9 years, SD=7.3), Gender (90% female), Child age (Mean=12.8 years, SD=7.3), Child Gender (78% male), CA ownership: (82% CA owners). Of the CA, 34% were dogs, 23% cats and 42% of participants had both a dog and cat. The Parenting Stress Index data revealed that 52% of parents believed their children were a major source of stress in their life. Health and safety risks to the CA include the report of 5% of all parents that a CA would be in danger in their household. Among CA owners 9% reported that their child "sometimes" harmed their pet. Barriers of CA ownership were also found for parents. Parents (25%) reported that their children were bothered or irritated by their pet. A small percentage (13%) of parents reported that their children were fearful of some CAs, and of those 9% identified dogs. Benefits of CA ownership included increased parental exercise, social interaction and relaxation. Parents reported that their children were attached to their CA (58%). The CA-owning children were reported most attached to dogs (38%) and cats (28%). A close relationship with their CA was reported by 78% of parents, and 94% reported that their CA made them feel happy. Parents (87%) indicated that their CA helped them stay healthy, and 82% reported their CA knew when they felt bad.

Conclusions:

Our findings reveal that CAs may be of particular benefit to parents of children with ASD by providing friendship and promoting health. This may be especially helpful given that the parents were under considerable stress, perceived to be largely associated with parenting.

213 **211.213** Impact of Autism-Focused Public Speech Training Using Simple Virtual Audience

H. Kumazaki[1], *T. Sumiyoshi*[2], *B. Yamagata*[3], *T. Muramatsu*[4], *M. Mimura*[3] *and M. Kikuchi*[1], *(1)Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan, (2)National Center of Neurology and Psychiatry, Kodaira, Japan, (3)Keio University, Tokyo, Japan, (4)Department of Neuropsychiatry, Keio University, School of Medicine, Tokyo, Japan*

Background: The employment rate for adults with autism spectrum disorders (ASD) is quite low, highlighting the need for support, programs, and tools that can assist them in acquiring and retaining jobs. In their employment, they are required to engage in public speaking from time to time. In the public speaking situation, interpreting the facial expressions of the audience, awareness of their own body language as projected to others, and sensory overload issues caused by the speaking environment might be challenging for individuals with ASD. Previous studies have shown that many individuals with ASD show motivation and an aptitude for using technology. They have been shown to have a preference for electronic media, game-like elements, and computer-generated speech, and those with particular visual strengths may be especially adept at engaging with digital modalities. In an effort to help facilitate public speaking training for individuals with ASD, we developed the Autism-Focused Public Speech Training using Simple Virtual Audience (APSV).

Objectives: The present study was carried out to evaluate the efficacy of APSV for individuals with ASD.

Methods: The virtual audiences used in APSV were simple human face as shown in Figure 1. They could nod, smile, and blink eyes. Young adults with ASD (ages 18–25 years) were randomly assigned to the following two groups: one group received "APSV" and the other group received "independent training" The subsequent trial procedures were conducted from day 1 to day 7. On days 1 and 7, the participants in both groups participated in an approximately 10-min mock public speaking trial in front of ten people at the same time of day. Baseline and outcome measurement of self-reported performance/efficacy and salivary cortisol were obtained before and after the mock public speaking respectively. From day 2 to day 6, participants in the APSV group were encouraged to undergo APSV for a minimum of 10 minutes. Participants in the independent study group were encouraged to read and answer materials about responding effectively to questions frequently asked in public speaking daily for a minimum of 10 minutes.

Results: In total, 23 individuals with ASD participated in the study. In the APSV group (n=11), all participants completed the trial procedures without technological challenges or distress that could lead to session termination. In the independent study group (n=12), two participants dropped out of the trial procedures. Young adults with ASD participating in the APSV sessions reported improved self-confidence and demonstrated lower levels of salivary cortisol compared to controls.

Conclusions: The study provides preliminary evidence that use of virtual agent-mediated systems, such as simple avatar, may be acceptable/feasible and contribute to tangible improvements in public speaking performance. Future studies need to examine whether APSV is associated with completing more job interviews and obtaining employment.

214 **211.214** Improving Daily Living Skills in College Students with Autism Spectrum Disorder Using a Peer-Mediated Daily Living Checklist Intervention

E. Engstrom[1], *R. L. Koegel*[2] *and T. W. Vernon*[3], *(1)Koegel Autism Center, UCSB Koegel Autism Center, Santa Barbara, CA, (2)Stanford Medical School, Stanford, CA, (3)University of California Santa Barbara, Santa Barbara, CA*

Background:

Research suggests individuals with Autism Spectrum Disorder (ASD) have difficulties with daily living skills that affect adaptive behavior, which are a major barrier to success in higher education settings and beyond. Few interventions target the improvement of daily living skills within this population, with even fewer targeting college students. Since interventions that integrate motivational and peer-mediated components have improved social communication in college students with ASD, it is possible that incorporating these methods into a daily living checklist, a type of self-management intervention, may lead to greater improvements in daily living skills for this population as well.

Objectives:

The purpose of this study is to assess whether the use of peer-mediated motivational components would increase the percentage of targeted daily living tasks completed per week. In addition, data was collected to systematically examine if this intervention will improve overall adaptive behavior, mental health, quality of life, and academics.

Methods:

Participants included three adults between 18 and 26 years diagnosed with ASD according to DSM-5 criteria. Participants were full time students in a four-year university, had average intellectual functioning, and demonstrated difficulties in at least one domain of daily living skills as measured by the Vineland Adaptive Behavior Scales- 3rd Edition (VABS-3).

A multiple baseline across participants design was used, where a baseline condition with a self-management daily living checklist without peer-mediation was compared to a peer-mediated intervention condition where individualized prompts are provided to complete the self-management daily living checklist. Participants were randomized to each baseline condition.

The primary dependent measure is the percentage of targeted daily living tasks completed per week. Additionally, secondary data was collected for the following measures pre and post intervention: (1) VABS-3 (2) Beck Depression Inventory-II (BDI-II); (3) Beck Anxiety Inventory (BAI); (4) Quality of Life Assessment for Adults with ASD; and (5) quarterly grade reports.

Results:

Preliminary data from two participants suggest that a peer-mediated daily living checklist intervention is effective in increasing frequency of daily living skills in college students with ASD (See Figure 1). At baseline, Participant 1 completed an average of 24% of targeted tasks per week. After the peer-mediated intervention began, Participant 1 increased the percentage of total targeted tasks to an average of 65%, which was maintained at one-month follow up. At baseline, Participant 2 completed an average 29% of targeted tasks per week. Preliminary data shows that Participant 2 is increasing in percentage of completed tasks, with an average of 78%. Additional analyses will confirm these findings in three participants and across pre-post measures.

Conclusions:

Preliminary results show promise that this peer-mediated intervention may be more effective in improving daily living skills among college students with ASD than without peer-mediation. The results suggest that future research on improving daily living skills for college students with ASD is likely to be successful.

215 **211.215** Improving the Social Interactions and Peer Perceptions of Adolescents with ASD: Results from a Randomized Clinical Trial of the START Socialization Program

***J. A. Ko**, A. R. Miller, A. Chiu, M. Allison, R. Graef, S. Said, A. Rathore, R. Rincon, A. Barrett, E. McGarry and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Social skill programs for adolescents with ASD rarely use live, real-world peer interactions as an outcome measure when these interactions are arguably the most important and socially valid evidence for meaningful socialization improvements. Instead, parent and self-report survey measures and structured social assessments are commonly used instruments to measure social skill gains (Miller et al., 2014). However, these tools may have limited value without converging evidence of real-world social improvements (Cunningham, 2012). Specifically, when these adolescents interact with similarly aged social partners, how are they perceived? Do they use the verbal and non-verbal skills that are generally associated with social competence? To date, no studies have examined if third party, untrained observers perceive social competence improvements in live peer interactions after completing a randomized clinical trial (RCT) of a social skills program.

Objectives: The current study evaluated the efficacy of an RCT of the Social Tools And Rules for Teens (START) program through directly observing and coding social skill use and obtaining peer perceptions of social ability based on brief video-recorded conversations.

Methods: Thirty-five adolescents (ages 12-17) and their parents participated in the RCT of the START program, which is a 20-week experiential social competence and motivation intervention. At pre- and post-intervention, adolescents engaged in 5-minute dyadic conversations with two unfamiliar, typically developing peers (one male and one female). Video-recorded conversations were coded for various social skills (i.e. questions asked, mutual engagement, speaking contributions, eye contact, listening behaviors, and positive facial expressions). Two video coders coded each behavior and reliability was established for 30% of the videos. The video-recorded conversations were also shown to peer observers (unknown to participants and blind to study objectives), who rated participants along several social domains (i.e. social skills, comfort during the interaction, awkwardness during the interaction, and perceived quality of existing relationships). Videos were counterbalanced to ensure that the pre-intervention video was not always viewed before the post-intervention video. Every participant video was rated five times by different raters to ensure consistency of ratings.

Results: Two-way mixed ANOVAs were performed to examine differences between the treatment and waitlist groups on video-coded social skills and peer perceptions of social ability across time. Results revealed significant improvements for adolescents who participated in the START program in the following social skills: questions asked (p = .035; medium-large effect), eye contact (p = .003; large effect), listening behaviors (p = <.001; large effect), and positive facial expressions (p = .009; large effect). Compared to a waitlist control group, adolescents who participated in the START program also demonstrated significant improvements peer perceptions of social ability made by observers unfamiliar with the study (p = <.001; large effect).

Conclusions: The START program resulted in significant gains in the adolescents' use of specific social skills, which in turn increased peer perceptions of their social competence. This is particularly promising, given that the social strategies one utilizes dictates how favorably one is perceived as a potential conversation partner and sets the foundation for building successful social connections and relationships.

216 **211.216** Inhibition Control Outcomes of a Music Intervention for Autism

***K. Jamey**[1,2,3], N. Foster[1,2,3], M. Sharda[1,2], C. Tuerk[1,2], R. Chowdhury[4,5], M. Tan[6], A. Nadig[7,8] and K. L. Hyde[1,2,3,7], (1)International Laboratory of Brain, Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada, (2)Psychology, University of Montreal, Montreal, QC, Canada, (3)Faculty of Medicine, Centre for Research on Brain, Language and Music, McGill University, Montreal, QC, Canada, (4)Psychology, International Laboratory of Brain, Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada, (5)See Things My Way Centre for Innovation in Autism and Intellectual Disabilities, Montreal, QC, Canada, (6)Westmount Music Therapy, Westmount, QC, Canada, (7)Faculty of Medicine, McGill University,*

Montreal, QC, Canada, (8)Centre for Research on Brain, Language and Music, Montreal, QC, Canada

Background: Music is a complex, multimodal activity which depends on and may in turn enhance inhibition control (IC) during cognitive development (Holochwost et al., 2017; Jaschke, 2018). IC is an executive function important for regulating appropriate and inappropriate responses and for adapting behavior to shifting situational demands. Individuals with autism spectrum disorder (ASD) have shown impairments on standard IC tasks such as the Go-NoGo (Geurts et al., 2014) and Eriksen Flanker tasks (Christ et al., 2011). However, no study has yet examined the effects of a music-based intervention for children with ASD using IC measures.

Objectives: The object of this study was to evaluate changes in IC measures in children with ASD after 8-12 weeks of a music or non-music intervention, using the Go-NoGo and Eriksen Flanker tasks.

Methods: Data were collected as part of a larger 8-12 week randomized controlled trial of music for school-age children with autism (Sharda et al, 2018). Both the music and non-music therapies targeted social and communication outcomes. Music sessions were individual, semi-improvisational and participants could choose from several instruments. The Go-NoGo task consisted of 160 Go and 40 NoGo trials, and the Flanker task consisted of 100 congruent and 100 incongruent trials. Both tasks were adapted for children. The IC analysis was run on 32 participants who had pre- and post-intervention data for the Go-NoGo task (MT, n=18; NM, n=14) and 29 for the Flanker task (MT, n=15; NM, n=14). Groups had average IQ and were matched on age, sex, IQ and socioeconomic status in both analyses ($p \geq .274$). Mixed-effects analyses tested changes in IC performance in the NoGo and incongruent conditions of the Go-NoGo and Flanker tasks respectively. Main effects of time-point and treatment by time-point interactions were examined for both accuracy and reaction time.

Results: On the Go-NoGo task, 8-12 weeks of therapy showed no significant treatment by time-point interaction on NoGo accuracy ($p = .393$; Figure 1). On the Flanker task, there were no significant treatment by time-point interactions for incongruent condition reaction times ($p = .519$) or accuracy ($p = .869$; Figure 2). There were also no overall main effects of time-point for the NoGo trials or for the Flanker task conditions on either reaction time or accuracy ($p \geq .260$).

Conclusions: IC performance was not significantly greater in children with ASD who participated in 8-12 weeks of music intervention compared to those in the non-musical intervention, and overall no changes in IC performance were found in either intervention. In the larger RCT, positive effects were previously found on communication scores for the music group compared to the non-music group (Sharda et al., 2018). Although the intervention may simply have been too short to observe IC improvements, previous work on music and IC suggests that a greater focus on rhythmic activities and rhythm-based interaction may be beneficial in music-based interventions where IC is a targeted outcome (Holochwost et al., 2017; Vuust et al., 2011). As such, these results may help guide the effectiveness of future music-based interventions in ASD.

217 **211.217** Interventions for Transition-Age Students with Autism Spectrum Disorder: A Meta-Analysis

S. M. Crowley[1]*, S. Y. Kim*[2] *and K. Bottema-Beutel*[2]*, (1)Boston College, Chestnut Hill, MA, (2)Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: The Individuals with Disabilities Education Act (Individuals with Disabilities Education Act [IDEA], 2004) is a legislative mandate that was passed to enhance the educational opportunities available for students with disabilities. This law outlines the necessary steps to prepare students for a transitional period from high school to adulthood. Special educators are required to develop appropriate goals with each student that will assist them throughout this transitional period. Despite these advances, students with Autism Spectrum Disorder (ASD) consistently lag behind their peers in terms of educational achievement. When compared to typically developing peers, these students have lower rates of competitive employment, post-secondary school attendance, independent living, and opportunities for success within the community (Taylor & Seltzer, 2011). Synthesizing the available research that targets transition-age students with ASD will aid in determining whether these interventions have a positive impact on students with ASD, and the particular domains in which these interventions show evidence of effectiveness.

Objectives: In this meta-analysis we examined high school intervention studies, considered broadly, for individuals diagnosed with ASD, Intellectual Disability, or Severe/Multiple Disabilities. Our primary aim was to determine the summary effect of high school interventions, and the effect size estimates across all intervention types. For the purpose of this presentation, we will focus solely on the reports that included individuals with ASD.

Methods: Electronic databases were the primary method to search for published journal articles and dissertations/theses. Attempts to locate "grey literature" were also employed through hand searching past conference proceedings and peer-reviewed journals. Researchers who previously presented on topics related to transition-age youth, were emailed with a request to provide unpublished data relevant to the current analysis. A graduate student screened each article based on inclusion criteria. If studies did not meet the criteria, they were eliminated from the meta-analysis; however, articles that appeared to meet this inclusion criteria, went on for a complete review of the text.

Results: Our search yielded a total of 18 reports and 208 effect sizes (see Figure 1 for a detailed description of the elimination process). Of the 18 studies included in the overall analysis, 8 included adolescent or young adult participants with ASD ($n = 78$). The forest plot in Figure 2 reveals a significant summary effect size for studies that introduced interventions for high school students with ASD. Because there were fewer than five studies in each intervention category, the findings could not be parsed out based on the type of intervention that was administered.

Conclusions: The small number of studies included in this meta-analysis further highlights the lack of knowledge there is regarding the benefits of interventions for individuals with ASD as they prepare for adulthood. Future research should continue to use rigorous methodologies to investigate transition interventions, and their impact on social-ecological factors that are considered important to autistic adults (Anderson, Roux, Kuo, & Shattuck, 2018).

218 **211.218** Is It Enough?: Challenges Generalizing Social Skills Gains into Community Settings

T. P. Gabrielsen[1] *and T. W. Jackson*[2]*, (1)Counseling & Special Education, Brigham Young University, Provo, UT, (2)Counseling Psychology and Special Education, Brigham Young University, Provo, UT*

Background: Group social skills training (GSST) is an important intervention approach to help children and adolescents with autism spectrum disorder (ASD) find more success in social engagement and inclusion. There are a number of well-established interventions that have been shown to help adolescents with ASD foster social relationships and improve in their skills relating to social interaction. However, there is a lack of

research reporting how the gains reported as a result of GSST generalize to other settings. Social knowledge gains have been observed, but social competence gains may not necessarily follow.

Objectives: The objective of this exploratory study was to see how well participants who had received an evidence-based social skills curriculum could generalize the skills learned to a community group setting. To enhance the likelihood of generalization, we designed the study to observe social gains before and after implementing a brief peer inclusion intervention involving the participant and their peers in their community group.

Methods: We provided GSST to 25 adolescents with ASD (ages 12-17) using a curriculum shown to have positive effects (the UCLA PEERS® curriculum) and measured the effect of training by parent report via two questionnaires: The Autism Social Skills Profile (ASSP) and Social Communication Questionnaire – Current (SCQ-Current). We then provided seven participants (six males, one female) and their peers in their community groups with a brief intervention teaching principles and strategies for peers, aimed at inclusion of those with disabilities without focusing on autism or our participants exclusively (e.g. Boy Scouts of America Disability Awareness Merit Badge). We analyzed each of these seven participants' level of social engagement in their community groups before and after the intervention using a multiple baseline design.

Results: Per parent report, GSST showed minor improvements in some areas of social engagement such as reciprocal conversation, reciprocal smiling, and a decrease in socially inappropriate questions or comments. Overall social engagement of participants in the community groups was not significantly changed, however. Peer inclusion instruction produced mixed results across participants, but generally there was no significant effect as a result of additional intervention for peers in the community setting.

Conclusions: Results from this exploratory study show that GSST can result in positive effects in areas of social communication quality and reciprocity as reported by parents. However, GSST may not be sufficient to produce desired levels of social engagement in generalized settings such as community peer groups. A number of challenges were encountered, especially in working with community group leaders. Considerations put forth as a result of this study include the importance of adult community group leaders as models for social engagement, providing opportunities for social engagement in novel peer groups, as well as consideration of parents of the possible benefits of having their child's disability disclosed to such peer groups to improve the potential gains of a peer inclusion intervention such as that proposed here. These considerations highlight the important role of families of individuals with ASD in providing opportunities for their teen with ASD to thrive socially.

219 **211.219** Is Sensory Integration Treatment an Evidence-Based Intervention for Children with Autism?

R. Schaaf[1], *S. A. Schoen*[2], *S. J. Lane*[3], *Z. Mailloux*[4], *T. A. May-Benson*[5], *D. Parham*[6] *and S. Smith Roley*[7], *(1)Thomas Jefferson University, Philadelphia, PA, (2)Sensory Processing Disorder Foundation, Greenwood, CO, (3)Occupational Therapy, Newcastle University, Newcastle, Australia, (4)Occupational Therapy, Thomas Jefferson University, Philadelphia, PA, (5)Spiral Foundation, Newton, MA, (6)Occupational Therapy, University of New Mexico, Albuquerque, NM, (7)CLASI - Collaborative Leadership in Ayres Sensory Integration., Aliso Viejo, CA*

Background:

The DSM-5 identifies sensory features (hypo and hyper reactivity, and unusual sensory interests) as a diagnostic characteristic of Autism Spectrum Disorders. These sensory features often interfere with functional skills, socialization and the development of higher-level behaviors. One intervention that is often recommended for addressing sensory features and their related impact on function and behavior is Ayres Sensory Integration© (ASI). ASI consists of principles and practices that provide clear guidelines for appropriate implementation. Despite the literature and guidance for using ASI, controversy continues to exists regarding its effectiveness. This session will present data from an analysis of evidence for ASI using 3 sets of standards designed to evaluate evidence-based practices for ASD. These standards provide specific criteria that are used to evaluate existing research, and are designed to guide educators, therapists, researchers, parents, policy makers, and others to identify effective interventions.

Objectives: To report on findings from a systematic analysis of literature regarding the effectiveness of ASI for children with ASD, 4-12 years old, published from 2006 to 2017; and to extend these finding by subjecting studies to two additional standards for evidence based practices reviews and adding any new data from 2018.

Methods:

METHOD: An extensive database search was conducted in CINAHL, Cochrane Reviews, Cochrane Trials, Embase, ERIC, Medline, and PsychINFO databases to identify relevant studies using the following search terms: sensory integration, autism, interventions suggesting a sensory integration approach. A total of 4,930 references were retrieved after removing duplicates. Only studies that used a high quality study designs (described below) were included. The iterative process of record reduction resulted in nineteen studies that were identified for further evaluation of fit with inclusion criteria. Only six of those studies met criteria for inclusion: e.g. peer-reviewed, written in English, intervention that is consistent with ASI intervention, provided an assessment of sensory functions prior to intervention, and used a comparison group design or single subject design. Prior to further analyses, three articles were excluded because the study intervention was not consistent with the core principles of ASI, or because of major methodological flaws. The remaining three studies were rated by three independent evaluators using the Council for Exceptional Children's Standards for evidence-based practice in special education (CEC, 2014).

Results: Two randomized controlled trials met 100% and 85% respectively of the CEC criteria with moderate to strong average intervention outcome effect sizes; Cohen's *d* equals .93, eta squared equals .21. One additional study met more than 50% of the criteria with an effect size of .23 which was calculated from the data.

Conclusions:

This analysis concludes that Ayres Sensory Integration meets the criteria for an evidence-based intervention for children with ASD. Additional data will be added and it will include a recently published(Kashefimehr, Kayihan, & Huri, 2018) and the application of additional review standards using the U.S. Preventive Services Task Force criteria and the National Clearinghouse on Autism Evidence and Practice Standards. Findings will be discussed in light of their implications for practice and research.

220 **211.220** Autism Spectrum Disorder Interventions in Mainland China: A Systematic Review

O. A. Sullivan *and C. Wang, Nankai University, Tianjin, China*

Background: Research on effective interventions for autism spectrum disorder (ASD) has historically been focused on Western populations.However, research in low- and middle-income countries is severely limited.This issue is particularly relevant given the majority of ASD measures and interventions were developed in high-income countries, with potentially limited relevance to low- and middle-income countries such as China(Elsabbagh et al. 2012).

Objectives: In light of the growing interest in ASD interventions in China, we systematically reviewed the academic literature to identify interventions to support individuals with ASD and their families in mainland China. This literature review seeked to determine the current state of ASD intervention research in mainland China, as well as trends from the past 25 years.

Methods: Using an identical search string, four databases – PubMed, PsycINFO, ScienceDirect, and Web of Science – were methodically searched for peer-reviewed studies conducted in mainland China on ASD interventions from 1995 to August 8th, 2018. Although 1,012 studies were initially found, reading abstracts from each study yielded 35 potentially suitable papers. After removing duplicates and reading full texts, only 13 English-language articles and nine Chinese-language articles were found to be suitable for inclusion.

Results: Half of included studies (*n* = 11) were published in 2017 and 2018, indicating a recent surge in research. Participants in all studies were either children or adolescents. The most popular interventions researched included acupoint-based (*n*= 5) and theory of mind (TOM)-based (*n* = 5) interventions. Studies demonstrated a spectrum of cultural adaptation of each intervention. All but one study concluded that their interventions were effective in mitigating specific ASD symptoms.

Conclusions: Although there has been a recent surge in research on interventions for ASD in mainland China, future studies must be longer, randomized, and placebo-controlled if possible. Additionally, studies should strive to include larger sample sizes consisting of participants of more diverse geographic and ethnic backgrounds throughout the country. Meanwhile, increased support must be given to teachers, therapeutic specialists, and caregivers of dependents with ASD.

221 **211.221** Home-School Collaboration and IEP and Postsecondary Goal Attainment of Students with ASD

L. A. Ruble[1], *J. H. McGrew*[2] *and M. Adams*[1], *(1)University of Kentucky, Lexington, KY, (2)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background: The school, student and family factors underlying poor postsecondary outcomes of students with autism spectrum disorder (ASD) are not well understood. Factors contributing to success for students with ASD who obtain employment or postsecondary education encompass three broad categories associated with transition planning: school, student, and parent-related variables. We collected measures representing each of these categories as part of an intervention to improve transition outcomes for students with ASD using the Collaborative Model for Promoting Competence and Success (COMPASS) a student-centered planning and teacher coaching intervention designed to support home-school collaboration. Because of the divergence of abilities in transition age youth with ASD, this framework accounts for the heterogeneity observed across the spectrum by emphasizing personalization of intervention plans and adaptation of EBPs.

Objectives: Our goal was to understand the relative contribution of student (IQ, adaptive and externalizing behaviors), parent (activation) and school variables (transition planning quality (TPQ), parent-teacher alliance) in predicting IEP and postsecondary goal attainment (a) in general and (b) by domain of postsecondary outcomes. We also wanted to know (c) who was responsible for implementation of plans for postsecondary goals? and (d) how progress of implementation of plans changed over time?

Methods: Twenty special education teachers and 20 students with ASD and their parents were recruited for an RCT of COMPASS. All students received special services under the educational category of autism and met the DSM criteria. Students mean age was 18.2 years. Forty percent were taught in general education full time; 20% in general and special education; and 40% in special education full time. Ninety percent of the students were male, 70% were White, 15% Black, 5% Asian, and 10% multi-racial.

Parents and teachers completed reliable measures of TPQ (Ruble et al., 2018), parent activation (Hibbard et al., 2005), and parent-teacher alliance (Abidin & Brunner, 1995). IEP goal attainment was evaluated at the end of the year by a rater unaware of group assignment. Postsecondary goal attainment was reported by teachers and parents. Pearson correlations controlling for group assignment were used to examine concurrent associations between variables. Friedman's multiple comparison test was used to understand progress in implementation of transition plans over time.

Results: Student IQ and adaptive behavior, TPQ, and alliance correlated with IEP progress, with postsecondary goal attainment generally and with student participation in training/education, specifically. However, only parent activation and student externalizing behavior correlated with employment. Families and students, rather than school personnel, were the primary persons in charge and in control of the implementation of postsecondary plans and required help across multiple coaching sessions to implement plans fully.

Conclusions: This preliminary study suggests that transition planning that integrates both home and school goals and implementation strategies is necessary. Interventions that support families and students should promote the accomplishment of postsecondary goals. These strategies include approaches that improve home-school alliance and transition planning quality.

222 **211.222** Trait Mindfulness in Treatment-Seeking Adolescents with Autism Spectrum Disorder and Comorbid Anxiety

T. M. Rutter[1,2], *S. Pickering*[2] *and R. Oti*[2], *(1)Seattle Pacific University, Seattle, WA, (2)Seattle Children's Hospital, Seattle, WA*

Background: Adolescents diagnosed with autism spectrum disorder (ASD) may face significant challenges in meeting social environment demands, potentially leading to distress (Russell, 2011). The co-occurrence of anxiety symptoms are common in adolescents with ASD; approximately 40% of youth with ASD have at least one comorbid anxiety diagnoses (van Steesel, 2011). Comorbidity in individuals with ASD shows relations to reduced quality of life (Chang & Wineman, 2014); thus, treatment to address comorbid diagnoses is crucial. Mindfulness-based stress reduction (MBSR) programs have shown promise as effective treatment for anxiety among both typically developing (TD) children (Zoogman, Goldberg, & Miller, 2015) and individuals with ASD (Conner & White, 2018; Sizoo & Kuiper, 2017). However, little is known about the clinical profiles of adolescents with ASD who present for MSBR treatment. Investigating these profiles may provide insight into factors impacting effective treatment for adolescents with ASD.

Objectives: Our aim was to develop an understanding of the relation between core symptoms of ASD and trait mindfulness in adolescents with comorbid anxiety presenting for MBSR treatment. We hypothesized that lower trait mindfulness would be related to higher pre-treatment

perceived stress scores and more severe autism symptoms.

Methods: A total of 27 patients participated in a group therapy that implemented the Mindfulness Based Stress Reduction for Teens curriculum (MBSR-T; Biegel, Chang, Garrett, & Edwards, 2014) for 10-12 sessions. Nine adolescents (M_{age} = 15.33 SD_{age} = 2.34) were included in this preliminary analysis. Prior to beginning the intervention, the Perceived Stress Scale (PSS; Cohen, 1994) was collected to determine perception of stress, the Social Responsiveness Scale -Second Edition (SRS-2; Constantino & Gruber, 2012) was completed by parents to measure ASD symptoms, and the Mindful Attention Awareness Scale-Adolescent version (MAAS-A; Brown, West, Loverich, & Biegel, 2011) was collected to determine trait mindfulness.

Results: An average PSS total score of 23.88 (n = 9; SD = 5.23) was in the moderate range at the beginning of intervention. The average pre-treatment MAAS-A score was 3.76 (n = 9; SD = 1.22), indicating moderate levels of trait mindfulness with a wide range across the clinical sample. The MAAS-A and PSS were negatively correlated (r = -0.86, p = .003). The SRS-2 Restricted and Repetitive Behaviors (RRBs) subscale had a negative association with the MAAS-A (r = -0.79, p = .010). A trend was observed between the Awareness subscale of the SRS-2 and the MAAS-A (r = -0.66, p = .053). No other SRS-2 treatment subscales were significantly correlated with the MAAS-A.

Conclusions: Results support prior research that reduced trait mindfulness is associated with greater perceived stress among adolescents with ASD. Average trait mindfulness for adolescents with ASD appears similar to TD peers (Brown, Loverich, & Biegel, 2011). Our study also provides preliminary evidence that lower trait mindfulness is associated with more RRBs in adolescents and less social awareness. Future research should examine whether RRBs and deficits in social awareness are impacted by mindfulness training or if these core autism symptoms function to moderate the therapeutic efficacy of MBSR.

Poster Session
212 - Late phase drug development
5:30 PM - 7:00 PM - Room: 710

223 **212.223** A Phase 2 Randomized, Placebo-Controlled Trial of Intranasal Oxytocin in Adults with Autism Spectrum Disorder

E. Anagnostou[1], *J. A. Brian*[1], *J. Goldberg*[2], *S. Prat*[3], *L. Capano*[4], *A. Iaboni*[1], *A. Solish*[1], *D. Frisch*[5], *R. Hastie Adams*[5], *L. Genore*[6], *I. Patriciu*[7], *F. Tran*[2,8] *and M. Woodbury-Smith*[9], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Psychiatry, McMaster University, Hamilton, ON, Canada, (3)McMaster University, Hamilton, ON, Canada, (4)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Holland Bloorview Kids Rehab Hospital, toronto, ON, Canada, (6)Holland Bloorview Kids Rehab Hospital - ARC, Toronto, ON, Canada, (7)McMaster University, toronto, ON, Canada, (8)Neurology, Sunnybrook Hospital, Toronto, ON, Canada, (9)Newcastle University, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland*

Background:
There are currently no medications with evidence supporting their use to treat the core symptoms of autism spectrum disorder (ASD). Convergent evidence, however, suggests a role for oxytocin in social function. Still, the data regarding potentially therapeutic potential of this compound remains mixed. Methodological limitations of previous studies include small sample sizes (median n = 18), variability in assay sensitivity of outcome measures used, and variability in dosing among others.

Objectives:

To evaluate the efficacy of intranasal oxytocin vs. placebo for the treatment of social deficits in adults with ASD, using a phase II Randomized controlled trial design

Methods: This is a phase II randomized, placebo controlled, multisite trial. Participants were recruited across 2 sites and were randomized to drug or placebo in 1:1 fashion. Safety was evaluated using the SMURF, safety blood work and ECG. Efficacy was evaluated using the CGI as a primary measure. Secondary measures included the ABC, SRS, WHOQOL, Vineland, and SCL-90 anxiety.

Results:

70 participants were randomized across 2 sites. Intranasal oxytocin was well tolerated with no related serious adverse events reported. Improvements were noted in self reported SRS (p=0.0006), WHOQOL psychological scale (p=0.08), anxiety (p=0.04) and Vineland total score (p=0.05)

Conclusions: Intranasal oxytocin was well tolerated in adults with ASD. Efficacy data is supportive of therapeutic potential for this mechanism.

224 **213.224** Family History of Autism and Assisted Reproductive Technology As Risk Factors for Pregnancy Complications in the Chatterbaby Autism Risk Survey

J. A. Estabillo[1,2], *P. Kaur*[3], *B. H. Dang*[4], *D. Montoya-Williams*[5], *J. Parga*[5], *C. Kasari*[3], *S. Jeste*[3], *M. Dapretto*[6], *S. Y. Bookheimer*[6], *Y. Quezada*[3], *S. J. Poulhazan*[7], *S. Zhang*[3], *A. Razzak*[3], *S. Yoon*[3] *and A. Anderson*[3], *(1)Psychiatry, UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Psychology, LSU, Baton Rouge, LA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Department of Neuroscience and Psychiatry, UCLA, Los Angeles, CA, (5)Division of Neonatology, CHOP, Philadelphia, PA, (6)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (7)Biology, University of California, Los Angeles, Los Angeles, CA*

Background: Mothers who use assisted reproductive technology (ART) are at higher risk for pregnancy and birth complications. Use of ART, family history of autism spectrum disorder (ASD), and pregnancy complications such as hypertension and abnormal bleeding have all been associated with increased risk for ASD. Given that ART pregnancies share many correlates with ASD risk factors (e.g., increased parental age, higher education

level, pregnancy and birth complications), we examined whether ASD family history may be associated with an increased risk of pregnancy complications, after adjusting for ART, maternal age, and maternal education, and tested whether various ART methods showed different risk profiles for pregnancy complications.

Objectives: Examine the relationship between ASD family history, ART, and pregnancy complications, and assess whether survey participants with self-reported ASD family history had more pregnancy complications (holding constant ART, maternal age, and maternal education).

Methods: Data were collected as part of a voluntary survey completed by any user of the infant cry translation app, ChatterBaby (n = 1,782, infant age M= 91 days). The "ChatterBaby Autism Risk Survey" obtains participants' consent for their information to be used in research, and queries demographic information, family history, and pregnancy and delivery complications (Figure 1). Of the total participants, 7.6% reported using any ART, 12.5% reported a family history of ASD, and 52.6% endorsed maternal pregnancy problems. To examine the general relationship between ART and pregnancy complications, a binomial logistic regression predicted pregnancy complications based on ART, maternal age, maternal education level, and family history of ASD. Secondary models examined specific relationships within type of ART.

Results: Pregnancy complications were significantly increased for mothers who used any ART (OR=1.66;p<0.05) and for those who had a family history of ASD (OR=1.66;p<0.001), holding constant maternal age and education (Figure 2). Mothers with a family history of ASD were not more likely to use ART (p>0.05) after holding constant maternal age and education. The relationships between maternal age, education, and pregnancy complications were specific to the nature of the complications. Different ART types showed different risk profiles for pregnancy complications. IVF, sperm donation, and embryo adoption did not result in a significantly higher risk for various pregnancy complications. However, mothers who used ICSI were more likely to experience depression requiring use of antidepressants[a]; hypertension[a]; preterm labor[b]; cerclage, cervical incompetence or insufficiency[c]; placental abruption[b]; placenta accreta[a]; hyperemesis gravidarium[a]; treatment with opioids[b]; perinatal or post-partum psychosis[c]; use of anticonvulsants to treat seizures[c]; intrauterine growth restriction[b]; preeclampsia/eclampsia[b]; and anemia[b]. Mothers who used egg donation were more likely to have hypertension[a]. Mothers who used IUI were more likely to have a history of miscarriage[b] and experience cerclage, cervical incompetence or insufficiency[a]. [Note: [a] = p<.05, [b] = p<.01, [c] = p<.001].

Conclusions: Mothers who use ART or with an ASD family history were significantly more likely to experience pregnancy complications, but mothers with ASD family history were not more likely to use ART. This suggests that ASD family history is a unique risk factor for pregnancy complications.

225 **213.225** From Early Childhood to Adolescence: Persistence and Impact of Emotional and Behavioural Problems in ASD

S. Chandler[1], *G. Baird*[2], *T. Charman*[3], *P. White*[1], *I. Yorke*[1] *and E. Simonoff*[1], *(1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:

High rates of co-occurring psychiatric disorders have been reported in adolescents and adults with autism spectrum disorder (ASD), and recent studies have also shown high rates of emotional and behavioural problems (EBPs) in young children with ASD. These problems can have a significant impact on the individual's ability to cope with daily life, over and above their core ASD symptoms. While additional psychiatric problems have been shown to persist in older children with ASD, far less is known about the stability and impact of EBPs in young children with ASD. This study seeks to address this issue using a three time-point community cohort with repeated measures.

Objectives:

As part of the Improving Autism Mental Health (IAMHealth; www.iamhealth.kcl.net) research programme, we aimed to: (1) assess the stability of EBPs across three time-points from early childhood to adolescence; (2) consider the association between early EBPs and later outcomes such as adaptive functioning.

Methods:

Participants were part of the QUEST cohort, a community-based sample of children with a diagnosis of ASD. Children were assessed at a mean age of 6-years 9-months (time 1, total n=277), 13-years 5-months (time 2, total n=211), and 15-years 4-months (time 3, total n=207). Parent/carers completed the Developmental Behaviour Questionnaire at time 1 and 2, and the Strengths and Difficulties Questionnaire at times 2 and 3 as a measure of their child's EBPs. Children's IQ was assessed at time 1, and (on a stratified subsample) at time 2. The Adaptive Behaviour Assessment System (ABAS-II) was completed at time 2, and psychiatric outcomes were assessed at time 3. This study focuses on 185 participants with data at all 3 time-points.

Results:

Parent reports of EBPs showed an overall decrease in total scores from time 1 to time 2 (t=4.18, p<.0001), but no significant difference was found between scores at time 2 and time 3. However, for those with high levels of EBPs at time 1, these problems persisted through to adolescence: 74% of those above the clinical cut-off on the DBC at time 1, remained above cut-off at time 2 (X^2 (1) = 27.0, p<.001); and of these, 81% scored in the high/very high range on the SDQ at time 3. Furthermore, higher levels of EBPs at time 1 were associated with poorer adaptive functioning at time 2, independent of IQ (β = -.19, (SE .08, p=.014).

Conclusions:

Within this community sample of children with ASD, we found a high level of EBPs in early childhood, with 76% scoring above the clinical cut-off on the DBC. For the majority, these EBPs persisted into late childhood and adolescence and were associated with lower adaptive functioning. These findings highlight the importance of identifying co-existing EBPs in children with ASD at an early stage, to enable timely interventions to be put in place, potentially reducing impact on the individual and their families.

226 **213.226** Gender Identity in Autism Spectrum Disorder and Attention Deficit Hyperactivity Disorder

J. H. Leef[1], *J. A. Brian*[2], *R. Easterbrook*[3], *J. Nguyen*[2], *A. Iaboni*[2], *A. Kushki*[4], *M. C. Lai*[5] *and E. Anagnostou*[2], *(1)Department of Applied Psychology and Human Development, University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)University of Guelph, Guelph, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada*

Background: Evidence suggests a higher-than-expected co-occurrence of autism spectrum disorder (ASD) and gender dysphoria (GD) in children, adolescents and adults (van der Miesen et al., 2015). GD is characterized by distress due to incongruence between assigned gender and experienced/expressed gender. Recent studies have found that ASD is more common among children who are clinically referred for GD compared to those referred for other psychiatric/psychological concerns (Leef et al., in preparation). Among youth with ASD, elevated traits of GD have also been found (e.g., May et al., 2017). These findings imply a unique relationship between ASD and GD. However, one study reported similarly elevated GD traits among youth with ADHD (Strang et al., 2014), suggesting that elevated rates of GD traits may not be unique to ASD versus other neurodevelopmental conditions.
Objectives: To explore whether traits of GD are elevated in children and adolescents with ASD relative to ADHD and controls.

Methods: Data from 644 participants enrolled in the Province of Ontario Neurodevelopmental (POND) Network were analyzed: ASD (*n*=370, *M* age=11.02, *SD*=3.32), ADHD (*n*=115, *M* age=10.03, *SD*=2.90), and typically developing controls (TD; *n*=159, *M* age=11.35, *SD*=3.20). We used one conventional method of assessing the propensity towards GD by analyzing a parent-reported item on the Child Behavior Checklist (CBCL) "wishes to be of opposite sex" (Item 110).

Results: Fisher's Exact Test revealed no significant association between endorsement of Item 110 and group (Fisher's Exact=1.38, *p*=.48; 2.2% in ASD, 1.7% in ADHD, and .6% in controls). Notably, of those for whom this item was endorsed, 73% had ASD, 18% had ADHD, and 9% were controls. Compared directly to controls, the ASD group had an Odds Ratio of 3.50; compared to ADHD, the Odds Ratio for ASD was close to 1 (.80).

Conclusions: This is one of the largest studies to explore a specific GD trait in a research-based sample of youth with ASD, ADHD and TD controls. The rate of endorsement of CBCL Item 110 did not significantly differ between ASD and ADHD. This finding is in line with Strang et al.'s (2014) report of clinically-referred youth with ASD and ADHD. The rate in the current controls was consistent with the CBCL non-referred standardization sample (i.e., .7%). It is noteworthy that, among those with this particular GD trait, the vast majority had ASD, and participants with ASD were 3.5 times more likely to have this GD trait than controls. This is consistent with recent findings that a significant proportion of children with GD have ASD (>20%; Leef et al., in preparation). Although this is a large sample, the number of individuals with this GD trait was quite small, making it difficult to conclude whether the link between ASD and GD is unique to ASD compared to other neurodevelopmental conditions. Further analyses will explore associations with other characteristics, including participant sex (i.e., birth-assigned gender), birth weight, repetitive behaviours, and pubertal stage.

227 **213.227** Higher Rates of Gender Diversity in Children with ASD Based on Self-Report, Not Parent Report

B. A. Corbett[1], *S. Ioannou*[1], *E. McGinn*[1], *R. A. Muscatello*[2] *and J. F. Strang*[3], *(1)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (2)Neuroscience Graduate Program, Vanderbilt University, Nashville, TN, (3)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC*

Background: Gender diversity refers to gender experiences that vary from common experiences of gender. One form of gender diversity is gender dysphoria, an incongruence between one's experienced gender and gender assumed at birth. Emerging research suggests an increased proportion of gender diversity in individuals with autism spectrum disorder (ASD), and over-representation of autism among individuals clinically referred for gender diversity and dysphoria. Previous research with youth has predominantly relied on parent-report based on a single parent-report item. Furthermore, the extent to which parent perceptions are consistent with child-report of gender diversity experiences is unknown.
Objectives: The current study compared the endorsement of gender diversity (i.e. dysphoria and agender experiences) in 147 children 10-to-13 years of age with ASD (11.31) and typical development (TD; 11.46). Additionally, parent perceptions of their child's gender diversity was compared between the groups. The prevalence of gender diversity and associations between self-and parent-report measures were investigated.

Methods: The Gender Development Scale Short Report (GDSSR) is a self-report (GDSSR-S) and parent-report (GDSSR-P) measure assessing the broad spectrum of gender-related characteristics in youth (Strang et al., 2017). Using the GDSSR, gender dysphoria and agender GDSSR-S variables were collected on 147 children with high-functioning ASD (N = 94) and TD (N = 53) and GDSSR-P from 122 parents of children with ASD (N = 78) and TD (N = 44). Item-level analysis of Child Behavior Checklist (CBCL) item 110, "Wishes to be the opposite sex" was also collected. Independent sample t-tests were used to compare group differences, Pearson correlations to examine associations, and cross-tab calculations to determine group proportions.

Results: There were significant differences between the groups showing children with ASD endorsing higher rates of experienced gender dysphoria t(145) = -2.63, p = 0.0001 and agender experiences, t(145) = -3.97, p = 0.0001. In contrast, there were no significant differences between the groups for GDSSR-P for gender dysphoria t(122) = -.73, p = 0.47 or agender experiences t(122) = -.52, p = 0.61 or CBCL Item 110 t(121)= -0.86, p = 0.39. Despite a lack of difference in parent reports between diagnostic groups, there were small-to-medium correlations between GDSSR-S and GDSSR-P dysphoria r = .26, p = 0.004; and CBCL Item 110 and GDSSR-S dysphoria r = .39, p = 0.0001 and GDSSR-P dysphoria r = .45, p = 0.0001. Using cross tabulation, the proportion of the ASD sample that reported gender dysphoria based on a strict cut-off of greater than 6 (Goldstein et al., 2017) was 4.3% whereas the TD sample was 0%.

Conclusions: Results extend recent reports showing increased rates of experienced gender diversity in children with ASD albeit based on self-report. There were no significant differences on parent-reports for children with and without ASD. Importantly, not all parents elected to complete the GDSSR-P due to religious or undisclosed reasons. Therefore, under-reporting of gender diversity is plausible. Findings corroborate clinical and research observations and underscore the need to better understand and support the unique and complex needs of children with ASD who experience gender diversity.

228 **213.228** Physical Exercise and Bone Fracture Rates in North American Children with Autism Spectrum Disorder

J. G. Gehricke[1], *J. Chan*[2], *J. G. Farmer*[3], *R. M. Fenning*[4], *R. steinberg Epstein*[1], *M. Misra*[5], *R. A. Parker*[6] *and A. M. Neumeyer*[7], *(1)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (2)Massachusetts General Hospital, Boston, MA, (3)General Academic Pediatrics, Massachusetts General Hospital for Children, Harvard Medical School, Boston, MA, (4)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (5)Pediatrics, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (6)Biostatistics, Massachusetts General Hospital and Harvard Medical School, Boston, MA, (7)Pediatrics and Neurology, Massachusetts General Hospital, Lexington, MA*

Background: Physical exercise has been shown to improve motor skills, physical fitness and social skills in youth with autism. However, children with autism may not exercise as much and have lower bone density than their typically developing peers.
Objectives: The study examined the frequency of physical exercise and bone fracture rates as well as underlying factors in children with Autism Spectrum Disorder (ASD).

Methods: We compared the reported frequency of recent physical exercise activity between children with ASD in the Autism Treatment Network (ATN) sample and national data derived from the National Survey of Children's Health (NSCH). In addition, we compared lifetime bone fracture rates in children with ASD in the ATN sample with relevant prior publications. Furthermore, we examined the contribution of demographic, child, and family (parent) factors on reported frequency of recent physical exercise activity and lifetime prevalence of bone fractures in children with autism.

Results: The results confirmed that the overall distribution of physical exercise rates were significantly different between the ATN and NSCH samples for 6-11 year old males ($p < 0.001$). Compared to the NSCH sample in the male 6-11 year old group, children with autism tended to exercise less often. A similar effect was seen across other age groups and in females, which was not statistically significant. Although the fracture prevalence rate increased by age group, no differences were found between children with autism and the general population.

Conclusions: The findings confirm that 6-11 year old boys with autism exercise less frequently compared to the NSCH sample. Although older children and girls with autism showed decreased frequencies in physical exercise compared to NSCH, the findings did not reach statistical significance. Fracture rates depend on both bone density and nature and frequency of physical activity. Fracture rates for children with autism increased by age group, similar to reported fracture rates in the general population, despite a lower frequency of exercise in children with autism. Demographic, child, and family (parent) factors did not contribute to the findings in a meaningful way. Future studies should include more heterogeneous samples as well as objective measures of physical exercise activity and bone density assessments to better understand predictors of physical exercise and bone fracture rates in this population.

229 **213.229** Identifying Underlying Sources of Distress for Adolescents and Adults with Autism Spectrum Disorders and Other Neurodevelopmental Disabilities

W. Worsham[1], *J. Davis*[2] *and D. A. Bilder*[3], *(1)University of Utah School of Medicine, Salt Lake City, UT, (2)Educational Psychology, University of Utah, Salt Lake City, UT, (3)Psychiatry, University of Utah, Salt Lake City, UT*

Background:
Individuals with Autism Spectrum Disorders (ASD) and other Developmental Disabilities (DD) who have low verbal ability often have difficulty communicating their sources of distress, discomfort or frustration. Often times these individuals communicate their needs indirectly through irritability and disruptive behavior. These behaviors can create a substantial barrier in their capacity to access appropriate medical care, participate in their community, and maintain residence with their parents or other caregivers. To address the needs of this population, medical providers must develop facility in translating observable behaviors to appropriate treatment protocols.

Objectives:

The primary objective of the current project is to convert parent and caregiver social capital (i.e. resources and knowledge) into improved behavioral and health outcomes for adolescents and adults with ASD and/or DD with minimal verbal ability. In addition, this project seeks to improve medical provider efficiency via a carefully designed and sequenced delivery of questions that focus on known behaviors associated with specific psychiatric and medical conditions in this population.

Methods:

The current study reports on qualitative data from six focus groups with 14 parents or caregivers of adolescents or adults with ASD and/or DD. Study participants completed an online assessment that was designed to indicate psychiatric or medical conditions using discreet behavioral indicators. The computer adaptive measure was created to follow a branching logic scheme where positive answers lead to expanded questions on specific topics. Our analysis followed a qualitative data methods outlined by Ritchie and Spencer (1994). Atlas.ti (version 5.1) software was used to organize and analyze the focus group data. The data interpretation plan followed several steps. First, we utilized inductive reasoning and the constant comparative method (Strauss & Corbin, 1998) by systematically comparing parent and caregiver statements within and across focus groups. Then, we focused on cross-group saturation in order to identify perspectives that represented community-wide beliefs among parents and caretakers. By analyzing data across the five focus groups, we were able to assess whether the perspectives that emerged from one group also emerged for the others, subsequently serving as a proxy for theoretical sampling in order to assess the meaningfulness of participant perspectives.

Results:

In the current study, all participants reported positive acceptability of the content of the measure. All participants also reported positive acceptability of the time required to complete the measure. Despite consistent positive remarks regarding the existing content, participants indicated a desire to expand content in several categories (e.g. gastrointestinal, self-injurious behavior, dental) and add categories that were not previously included (e.g. gynecological/menstruation).

Conclusions:

The current project documents the development and initial validation of a measure designed to support medical providers in caring for minimally verbal adolescents and adults with ASD and/or DD. This initial study showed positive acceptability for the content and structure of the question algorithm. While efficiency of the measure was a goal in the initial design, focus group participants called for expanded content in several key areas. This feedback has led to more comprehensive coverage of medical and psychiatric considerations that impact individuals with ASD and/or DD.

230 **213.230** Initial Somatic Assessment during the Autism Spectrum Disorder Diagnostic Process : A Systematic Review of International Clinical Guidelines

T. Dauchez[1], *A. Amestoy*[2] *and M. P. Bouvard*[3], *(1)Pôle Universitaire de Psychiatrie de l'Enfant et de l'Adolescent, Centre Ressources Autisme Aquitaine, Centre hospitalier Charles Perrens, Bordeaux, France, (2)Centre hospitalier Charles Perrens, Pôle Universitaire de Psychiatrie de l'Enfant et de*

l'Adolescent, Centre Ressources Autisme Aquitaine, Bordeaux, France, (3)Centre hospitalier Charles Perrens, Pôle Universitaire de Psychiatrie de l'enfant et de l'adolescent, Centre Ressources Autisme Aquitaine, Bordeaux, France

Background: Autism Spectrum Disorders (ASD) are neurodevelopmental disorders highly associated with various somatic conditions that can be hidden by core symptoms of ASD and complicate diagnosis.
Objectives: Identifying co-occuring disorders challenges the best effective health and social care in this population and influence the long-term outcome[1,2]. Process of ASD diagnosis have to integrate systematic somatics investigations in order to adjust medical and social supports.

Methods: A systematic review of international clinical guidelines for ASD diagnosis assessment published from 1 January 2005 was performed. Thirteen international guides were selected. We first conducted a quality appraisal selection, according to the Appraisal of Guidelines Research and Evaluation, second edition tool[3]. Then, we performed a comparative analysis of selected documents on the basis of co-occurring somatic disorders investigations process.

Results: Although the international clinical guidelines are heterogenous in quality (methodological score lies between 33 for the American Academy of Pediatrics clinical report[4] and up to almost 100 for National Institute for Health and Care Excellence guideline[5,6]), they share homogeneous content concerning initial somatic assessment. Somatic disorders described in all guidelines are frequent and achieve consensus. In all guidelines, initial diagnosis processes are mainly recommended to be performed by a multidisciplinary team involving pediatric, neuropediatric and genetic specialists. Clinicals examinations appeared to be base for the assessment of somatic conditions in the guidelines. Systematic genetic investigations are recommended by 40% of the guidelines, and metabolic, electroencephalographic or imaging investigations were mostly recommanded when indicated by the presence of warning signs for clinicians.

Conclusions: In accordance with this results, to perform a systematic and comprehensive initial somatic assessment during the ASD diagnostic process, multiple specialists are required and consensuel warning signs must be screened. In order to help clinicians and coordinate between professionals in the process, an « addressing tool » that could be a coordination tool between professionals would be helpfull. This tool may provide support for a systematic screening that can reinforce epidemiological data on somatics co-occurring disorders in ASD.

231 **213.231** Investigating the Relationship between Social Anxiety and Social Insight in Autistic and Neurotypical Adults, Using a Novel Experimental Task.

H. R. Pickard[1] *and F. Happé*[2]*, (1)Social, Genetic and Developmental Psychiatry, King's College London, London, United Kingdom, (2)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Social anxiety is elevated amongst autistic adults. Despite the high prevalence rates, there is limited research exploring the cognitive mechanisms underpinning the development of social anxiety in autistic adults. Recent research has proposed that autistic individuals who show an enhanced awareness of their own social difficulties, termed social insight, may be at an increased risk of developing social anxiety. This enhanced social insight may bring to light the difficulties a person faces during social interactions, thus contributing towards increased anxiety of future social situations where these known difficulties may lead to a failure to interact with others. To date no research has explored the relationship between social insight and social anxiety at either a clinical or subclinical level. This is primarily due to the lack of robust experimental measures of social insight, compared to theory of mind or emotion recognition measures.
Objectives: In the present study, we developed a novel online dynamic video-based experimental task to measure social insight, called the Social Signals Task. Using our novel Social Signals Task, we aim to explore the relationship between social insight and social anxiety in autistic and neurotypical adults who experience varying degrees of social anxiety.

Methods: We employed a mixed experimental design using both cognitive tasks (Social Signals Task, word recognition task) and questionnaires (social anxiety, autistic traits, anxiety, depression, alexithymia and self-esteem). The Social Signals Task consists of 60 videos showing a listener in a conversational dialogue. Participants are asked to judge the non-verbal social cues of the person in the video across three dimensions 1) interest, 2) understanding and 3) agreement. Participants also rate their level of confidence in their response. The Social Signals Task measures an individual's ability to recognise naturalistic social cues, as well as an individual's awareness of their ability to recognise these social cues. A sample of 141 adults (81 autistic adults, $Mean_{age}$ = 39.16) took part in our online study.

Results: We have recently completed data collection for this project. As such, we will conduct analyses at both a group-level and individual-level to examine the relationship between social insight and social anxiety for autistic and neurotypical adults. Correlational analyses, multiple linear regressions and Receiver Operating Curve analysis will be reported and presented.

Conclusions: The present research will have important implications for understanding the cognitive mechanisms associated with social anxiety in autistic and neurotypical adults. Research investigating the impact of social insight in socially anxious autistic adults is important for understanding whether social insight is a distinct mechanism contributing towards the development of social anxiety in this population. This research hopes to inform interventions used to help alleviate symptoms of social anxiety in autistic adults, who often experience increased insight into their own social difficulties.

232 **213.232** Kids Who Are Missed: Parent and Provider Perspectives on the Challenges Identifying Anxiety Difficulties in Youth with ASD within School Setting

M. Morris[1], *N. Reyes*[2], *K. Pickard*[3], *T. Tanda*[4] *and J. Reaven*[2], *(1)University of Colorado Anschutz Medical Campus, Aurora, CO, (2)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (3)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (4)Developmental Pediatrics, Children's Hospital Colorado, Aurora, CO*

Background: Children with autism spectrum disorder (ASD) tend to experience high rates of co-occurring anxiety disorders that impact their functioning across home and school settings. Identifying co-occurring anxiety symptoms within school settings is critical, and particularly for underserved and diverse youth who may not receive services elsewhere. Currently, little is known about parent and school personnel views regarding challenges tied to identifying anxiety in diverse youth within school settings.

Objectives: This study aimed to understand key stakeholders' (i.e., parents, school personnel) views regarding: 1) children with ASD whose anxiety symptoms tend to be missed; 2) why they perceive that these children are missed; and 3) potential strategies to better identify anxiety in diverse youth with ASD within school settings.

Methods: The present study presents a subset of data from the first phase of a large-scale, community-engaged implementation trial aimed at adapting a group CBT program for youth with ASD and co-occurring anxiety (i.e., Facing Your Fears-FYF; Reaven et al., 2018). A total of 14 focus groups were convened with parents (n=8) and school personnel (n=6) across three underserved school districts. Parents had at least one child with ASD and co-occurring anxiety and school personnel included a range of backgrounds (e.g., special education teachers, speech and language pathologists, school psychologists), but all had experienced working with youth with ASD. The focus group guide included semi-structured questions around identification of children with ASD who show anxiety related difficulties. Focus groups were audio-recorded and transcribed verbatim. Using an inductive, team-based approach, the transcripts were coded and analyzed by a multi-disciplinary team using standard qualitative methodology.

Results: Stakeholders reported that children with ASD have anxiety symptoms that are missed when they are: (1) from diverse backgrounds; (2) within a general education setting, and (3) not attending school due to avoidance. Stakeholders also indicated that children are missed because anxiety related difficulties are misinterpreted by school personnel as behavioral problems, and this misinterpretation might happen more with students of color, as school personnel may attribute anxiety related difficulties to problems in the students' home environment (e.g., living in poor neighborhoods). Additional factors affecting under-identification of anxiety symptoms include: (1) parents' lack of awareness or denial of their child's anxiety symptoms; (2) reluctance to label their child due to mental health stigma, and (3) limited knowledge on how to best advocate for their child. Finally, stakeholders noted that better training in identifying anxiety is needed for school personnel, as well as building families' understanding of mental health needs through family partnerships.

Conclusions: Findings from the present study suggest that a portion of children with ASD who experience anxiety are not identified. The findings highlight the challenges identifying anxiety in diverse youth with ASD, including biases associated with mental health and behavior. Strategies to better identify children with ASD and anxiety related difficulties were also identified. Future research is needed to explore ways to support school staff in identifying anxiety symptoms in children from diverse backgrounds and to support families in anxiety knowledge and mental health stigma.

233 **213.233** Links between Autism Spectrum Disorder and Sleep Difficulties

D. Crocetti[1], *C. Holingue*[2,3], *A. Spira*[3,4,5], *S. H. Mostofsky*[1,6] *and H. E. Volk*[2,3,7], *(1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (4)Department of Psychiatry and Behavioral Sciences, Johns Hopkins School of Medicine, Baltimore, MD, (5)Johns Hopkins Center on Aging and Health, Johns Hopkins University, Baltimore, MD, (6)Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, (7)Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background:

Disturbed sleep is very common among children with ASD and can be conceptualized as a consequence of ASD. However, poor sleep may also influence behavioral or cognitive traits among individual with ASD.

Objectives:

To compare sleep of children with autism spectrum disorder (ASD) with that of typically developing (TD) children and to assess associations of sleep with quantitative measures of ASD-related traits and with intellectual disability.

Methods:

Participants included 151 children with high-functioning ASD and 294 TD children (ages 8-12 years) whose parents completed the Children's Sleep Habits Questionnaire (CSHQ). Multivariable linear regression models were used to: 1) Examine associations between ASD and CSHQ subscales and total CSHQ score, and 2) Examine associations of CSHQ total score with social responsive scale (SRS) total score and the WISC-5 full scale IQ, within both ASD and TD groups. All models were adjusted for age, sex, race, ethnicity, and family socioeconomic status.

Results:

Among children with ASD, 64% reached the CSHQ threshold for a pediatric sleep disorder (score >41) compared to 27% in the TD group (χ^2=56, p<0.00001). After adjusting for potential confounders, ASD was significantly associated with all CSHQ subscales and the total score. Specifically, compared to children with TD, those with ASD exhibited greater bedtime resistance (Beta=1.1), greater delays in sleep onset (Beta=0.5), shorter sleep duration (Beta=0.8), higher sleep anxiety (Beta=1.2), more night wakings (Beta=0.6) and parasomnias (Beta=0.8), greater daytime sleepiness (Beta=2.2), and a higher total score for sleep problems (Beta=6.7) (all p<0.00001). Children with ASD also had 5 times the odds of meeting the clinical threshold for a pediatric sleep disorder (OR = 5.0, p<0.00001). The only sleep item not significantly associated with ASD status was sleep-disordered breathing (Beta=0.1, p=0.4). In both the ASD and TD groups, CSHQ total score was significantly associated with SRS total score (ASD Beta=0.2, p<0.05; TD Beta=0.3, p=0.003). In both the ASD and TD groups, there was no significant association between IQ (WISC-V full scale) and CSHQ total score.

Conclusions:

Compared with TD peers, children with ASD show significantly worse parent-reported sleep problems, including: bedtime resistance, shorter sleep, greater delays in sleep onset, more sleep anxiety and wakings, as well as greater daytime sleepiness. Reports of sleep-disordered breathing did not differ between children with ASD and TD, consistent with previous literature showing low endorsement of sleep-disordered breathing items in ASD samples. We also found significant associations between total CSHQ score and total SRS score within both the ASD and TD groups, suggesting a relationship between sleep health and social-communicative behavior that is not specific to ASD. We did not find any evidence of an association between total CSHQ and IQ in either the ASD or TD group. Further research is needed to examine the role of sleep problems in ASD behaviors, comorbid psychopathology, and medical conditions.

234 **213.234** Links of Comorbid Medical Conditions for Autism Spectrum Disorders between Parents and Their Affected Children

ABSTRACT WITHDRAWN

Background:

Many medical conditions have been reported to co-occur with autism spectrum disorder (ASD) in the same individual. However, it is not well known if these conditions also present in the parents of ASD children and if the parents' conditions are directly associated with the medical conditions in their children. Given the prevailing broad autistic phenotypes in the parents of ASD children, we hypothesize that there is a shared etiology between ASD and some of its comorbid medical conditions, which links these conditions across generations in families with ASD-affected individuals.

Objectives:

To investigate if comorbid medical conditions in ASD-affected individuals could be attributed to the conditions in their fathers and/or mothers.

Methods:

From the Manitoba Population Research Data Repositoryin Canada, we identified all the ASD-affected individuals who were born between April 1979 and March 2010 and had the universal health care coverage for at least five years since birth. The ASD-affected individuals were matched with up to six controls using the propensity score method. An individual was regarded as an ASD case if he/she had at least two hospital and/or medical claims for ASD (based on the International Classification of Diseases, 9thedition code 299) after age two and at least one of the claims was made by a paediatrician or psychiatrist.

Information about the medical conditions, which affect the gastrointestinal, mental health, and neurological systems, was also collected from the Data Repository. Generalized linear mixed models were used to identify the ASD-associated medical conditions using the cases and their matched controls. Logistic regression was performed to estimate the contribution from the parents to the occurrence of the medical condition in the ASD-affected individuals.

Results:

After quality control, 1,933 ASD-affected individuals, 11,390 matched controls, and their parents were selected. Of the 100 medical conditions from the three disease categories, 30 had a prevalence ≥1% in either the ASD-affected individuals or their matched controls. Of these, 22 conditions were significantly associated with the increased ASD risk ($p<0.0016$ after Bonferroni correction for 30 multiple comparisons).

Five of the 22 medical conditions in the ASD cases could be attributed to one or both parents (all $p<0.001$): episodic mood disorders (ICD9 code 296 –mothers), anxiety, dissociative and somatoform disorders (ICD9 code 300 –mothers), depressive disorder, not elsewhere classified (ICD9 code 311 –mothers), and hyperkinetic syndrome of childhood (ICD9 code 314 –both parents), and functional digestive disorders, not elsewhere classified (ICD9 code 564 –both parents). The estimated effects (odds ratios) ranged from 1.93 to 3.45 for the mothers and from 1.59 to 5.42 for the fathers. Similar findings were obtained when our analyses focused on the parents' medical conditions before the birth of their first child and when the parents of the cases were compared to the parents of the controls.

Conclusions:

Our preliminary results show that some of the comorbid medical conditions in ASD-affected individuals could be linked to their parents' conditions, which suggests that genetic and/or environmental factors shared between parents and children may cause the occurrence of comorbid medical conditions in ASD-affected individuals.

235 **213.235** Loneliness Mediates the Association between Friendship, Autism Symptoms, and Mental Health in Young Adults with Autism

H. K. Schiltz[1], *A. J. McVey*[1], *B. Dolan*[2], *K. Willar*[3], *S. Pleiss*[4], *M. Baalbaki*[1], *N. Gordon*[5] *and A. V. Van Hecke*[5], *(1)Marquette University, Milwaukee, WI, (2)Medical College of Wisconsin, Milwaukee, WI, (3)Stanford University, Stanford, CA, (4)Great Lakes Neurobehavioral Center, Edina, MN, (5)Psychology, Marquette University, Milwaukee, WI*

Background: Mental health concerns are often tied to social experiences; psychological health can be supported by friendship and deteriorated by loneliness. Core challenges of Autism Spectrum Disorder (ASD) may hinder the development and maintenance of friendships, and, in turn, elicit loneliness and poor mental health. Few studies, however, have explored these associations. In adults with ASD, one study found that loneliness and friendship each explained unique variance in anxiety and depression (Mazurek, 2014). Another study identified a mediating role of social connectedness and loneliness in the association between the Broader Autism Phenotype (BAP) and internalizing symptoms among typically developing young adults (Stice & Lavner, 2018).

Objectives: The current study sought to replicate and extend these findings in a sample of young adults with ASD, and more specifically, test the mediating role of loneliness in the associations between 1) friendship and mental health and 2) ASD symptoms and mental health (Figure 1).

Methods: Fifty-two young adults with ASD completed a battery of questionnaires assessing social and emotional functioning as part of a larger study of the PEERS® intervention; pre-intervention data was used in the present analyses. ASD was confirmed using the ADOS-G (Lord et al., 2000). Measures included in the current study were the Friendship Questionnaire (FQ), the Social Phobia Inventory (SPIN), the Autism Quotient (AQ), the Beck Depression Inventory (BDI), and the Social and Emotional Loneliness Scale for Adults (SELSA). Analyses in MPlus Version 7.4 involved composite scores on the SPIN, AQ, and BDI, an item on the FQ on number of get-togethers, and the social loneliness subscale of the SELSA.

Results: A series of path analyses were used to test the hypothesized model for each anxiety and depression (Figure 1). Friendship (*b*=-0.47,

p=0.01) and autism symptoms (*b*=0.27, *p*=0.03) explained unique variance in social loneliness. Loneliness was a significant predictor of anxiety (*b*=0.53, *p*=0.00) and depression (*b*=0.50, *p*=0.00), controlling for the effect of friendship and autism symptoms (both *ns*). Results also indicated that there were indirect effects of friendship (anxiety: *b*=-0.25, *p*=0.01; depression: *b*=-0.23, *p*=0.02) and autism symptoms (anxiety: *b*=0.14, *p*=0.05; depression *b*=0.14, *p*=0.07) on mental health through loneliness. All direct and indirect effects were significant, except the marginally significant indirect effect of friendship on depression through loneliness.

Conclusions: Findings of the present study suggest that loneliness may be a vulnerability factor for mental health concerns among young adults with ASD. Based on the current analyses, loneliness may stem from a combination of core autism symptoms as well as secondary effects of autism, namely, less social contact. While these effects are likely related, they appear to contribute independently to loneliness. Moreover, in contrast to previous results in ASD and in parallel with findings on the BAP, the current study did not identify friendship and loneliness as independent predictors of mental health concerns, but instead found a mediational pathway. Thus, the current study highlights that loneliness is a core contributor of mental health concerns in ASD, which may be ameliorated by improving social challenges and facilitating the development of meaningful friendships.

236 **213.236** Medical and Physical Health in Children with Intellectual Disability of Genetic Aetiology with and without ASD

A. C. Watkins[1], *H. R. Denyer*[1], *J. Wolstencroft*[2], *M. Erwood*[1], *R. Srinivasan*[3], *I. D. Imagine*[1] *and D. H. Skuse*[4], *(1)UCL GOS Institute of Child Health, London, United Kingdom, (2)UCL GOS ICH, London, United Kingdom, (3)UCL GOS ICH, London, United Kingdom of Great Britain and Northern Ireland, (4)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Background: Intellectual disability (ID) is characterised by limited cognitive ability and adaptive behaviour. Children with ID of genomic origin have an excess of physical health problems, but little is known about the quality and severity of medical complications in those with an associated Autism Spectrum Disorder.
IMAGINE-ID is a national UK study of over 3000 children with ID of known genetic origin (CNV or SNV). Here, we present preliminary data on the frequency of physical health difficulties of a subset of children with and without ASD.

Objectives: To ascertain whether the range and severity of physical health problems is different in children with ID/ASD of genetic origin from those without associated ASD. To compare the genetic aetiology of physical health difficulties in these groups.

Methods: Caregivers of 209 participants (aged 4-18) completed the Development and Wellbeing Assessment (DAWBA) and a comprehensive Medical Questionnaire online (62.2% had a CNV and 37.8% an SNV). Diagnoses of ASD were made by experienced clinicians, based on the DAWBA standardized interview, which has been validated by ADI/ADOS algorithms. A standardized Medical Questionnaire was administered to record medical history, current physical health and developmental milestones.

Results: Most participants had moderate to severe ID**.** 44.5% met diagnostic criteria for ASD, 62.4% of whom were male (53.4% of non-ASD). Mean age was 9.36 (SD 4, range 4-18) years. There were no significant group differences in chronological, developmental or language age between those with and without ASD. Children with ASD had more stomach and/or gut problems (46.2% vs 29.3%, p = .035), sleep difficulties (75.3% vs 57.8%, p = .006) and food and/or eating problems (60.2% vs 39.7%, p = .007) than those with ID alone. ASD was also associated with extreme food rituals, habits or preferences (50% vs 26.1%, p = .016).

Eye problems were more frequently associated with SNVs than CNVs (66.2% vs 50%, p = .024), as were muscle or movement difficulties (79.7% vs 56.6%, p = .003), seizures (39.2% vs 18.9%, p = .005), genital problems (23% vs 11.5%, p = .025) and bone or skeletal difficulties (29.7% vs 14.8%, p = .036). A higher proportion of SNV-carriers (48.6%) than CNV-carriers (43.4%) met criteria for an ASD, but the difference was not statistically significant.

Conclusions: Our findings indicate that high rates of physical health problems are associated with ID caused by a pathogenic CNV or SNV. Children with ID of genetic origin with associated ASD are at much higher risk of gastrointestinal problems, disturbed sleep patterns and eating difficulties than those with ID alone. Regardless of ASD diagnostic status, children with SNVs are at an enhanced risk of physical health difficulties, including muscle/movement difficulties, bone/skeletal difficulties and genital problems compared to children with CNVs. Children with SNVs had twice the risk of developing seizures compared to those with pathogenic CNVs. Recent findings by others have identified a higher proportion of pathogenic SNVs than CNVs among families with an epileptic child (Tsuchida et al., 2018).

237 **213.237** Parental Perspectives on Psychiatric Comorbidities in 989 Preschoolers with Autism Spectrum Disorder: Findings from an Italian Multi-Centric Study

F. Muratori[1,2], *M. Turi*[3], ***M. Prosperi***[1,2], *A. Narzisi*[2], *G. Valeri*[4], *S. Guerrera*[4], *E. Santocchi*[2], *F. Apicella*[2], *C. Lattarulo*[3], *S. Calderoni*[1,2] *and S. Vicari*[4], *(1)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (2)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (3)Fondazione Stella Maris Mediterraneo, Chiaromonte (Potenza), Italy, (4)Child and Adolescence Neuropsychiatry Unit, Department of Neuroscience, Children Hospital Bambino Gesù, Roma, Italy*

Background: An increased prevalence of psychiatric comorbidity (PC) in individuals with Autism Spectrum Disorders (ASD) is consistently reported and it is associated with a poorer prognosis and with a great psychological distress in families. While several studies have examined PC in school-aged children, adolescents and adults with ASD, investigations on PC in preschoolers are lacking. The difficulty to find properly and easy-to-use diagnostic tools to detect PC in ASD preschoolers could contribute to the relatively sparse studies in this area.
Objectives: We explore the prevalence and type of PC in a wide sample of ASD preschoolers through the DSM-Oriented Scales (DOS) of the Child Behaviour Checklist (CBCL 1.5-5) and their possible links with the core features of ASD and cognitive functioning. The role of the psychiatric Multi-Comorbidity was also discussed.

Methods: The sample included 989 ASD preschoolers (age-range: 16-75 months; M: 44.0 months; SD: 13.8 months) recruited by three different Italian care centers for children. These children were selected among individuals who received a diagnosis of ASD based on DSM 5 criteria. Included subjects were assessed using ADOS (ADOS-G or ADOS-2) and a standardized cognitive evaluation (LIPS-R, GMDS-ER or WPPSI tests) while their mothers completed the CBCL 1.5-5. The severity of autism was measured through the Calibrated Severity Score based on ADOS Total score and Social Affect (SA) and Restricted Repetitive Behaviors (RRB) sub-scores. The borderline and clinical DSM-Oriented Scales (DOS) scores of CBCL

1.5-5 were used to explore psychiatric comorbidity.

Results: About 37.8% of the sample had at least one PC in addition to ASD; these subjects displayed significantly higher Total score (p=0.02) and Social Affect score (p=0.003) on the ADOS-based calibrated severity scores (CSS), as well as lower (p=<0.0001) performance IQ (pIQ) compared to ASD individuals without PC. As far as the specific DOS, Affective Problems (AP) were detected in 23.4% of the whole sample, ADHD Problems (ADHD) in 17.3%, Anxiety Problems (ANXP) in 16.7%, and Oppositional Problems (OP) in 7.9%. These different comorbidities were isolated in 195 subjects (Mono-Comorbid group: 19.7% of the whole sample), while 179 subjects (18.1% of the whole sample) had two or more types of PC (Multi-Comorbid group). One-way ANOVA revealed that the Multi-Comorbid group had statistically significant lower pIQ and higher Total score and Social Affect score on CSS-ADOS. The 10% of total sample had relevant sleep problems.

Conclusions: This study suggests that in people with ASD, PC occur early in life worsening ASD symptoms and cognitive functioning necessitating the need for their early detection in order to plan tailored interventions. The use of parental questionnaires as screening tools to investigate PC could anticipate the individuation of psychiatric symptoms different from autism, contributing in diminishing the consistent risk for mis- or under-diagnosis PC in young children with "ASD and PC".

238 **213.238** Parents' Perspectives of Physical Activity Participation Among Adolescents with Autism Spectrum Disorder

*S. Gregor[1], N. Bruni[1], P. Grkinic[1], A. Mcdonald[1], L. Schwartz[1], S. Gabison[1], P. Thille[2], B. Gibson[3] and **P. Jachyra**[4], (1)Physical Therapy, University of Toronto, Toronto, ON, Canada, (2)College of Rehabilitation Science, University of Manitoba, Winnipeg, MB, Canada, (3)Physical Therapy and Bloorview Research Institute, University of Toronto and Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Adolescents with Autism Spectrum Disorder (ASD) are less likely to be physically active compared to their age-related peers. Given that adolescents with ASD become even less active during adolescence, they are at higher risk of developing debilitating health conditions. As such, they are more likely to develop obesity, cardiovascular disease, diabetes, musculoskeletal disorders, anxiety, and depression due in part to lower levels of physical activity. Given these potential health challenges among adolescents with ASD, there is a need to examine how to potentially enhance physical activity participation.

Objectives: Despite the health and social benefits of participation, little is known why they are predominantly physically inactive. Furthermore, there is a paucity of research that has examined the psychological, social, personal and structural mechanisms that influence their participation. With no previous research in Canada, this study examined parents' perspectives and experiences of physical activity participation to examine the barriers and facilitators of participation.

Methods: Ten in-depth interviews were conducted with parents of adolescents with ASD. Interviews were analyzed thematically.

Results: Findings suggest that parents prioritized behavioural and communication interventions over physical activity throughout their adolescent's life. This prioritization was most pronounced during childhood, and the lack of participation during their formative years shaped physical activity interests in adolescence. Second, parents also described experiencing systemic challenges when accessing physical activity programs, including a lack of awareness of ASD among service providers, funding challenges, and limited/few program options. Third, the lack of physical activity individualization and competing commitments contributed to tremendous strain on families. Fourth, the findings suggest early guidance is needed to help parents balance family life, schooling, and therapies with physical activity, as this may improve physical health and facilitate social development with peers.

Conclusions: The study suggests that a family-centred, multidisciplinary collaborative approach that includes health care practitioners such as physical therapists can potentially be used to facilitate the incorporation of physical activity into everyday life. Policy and community efforts are required to break down systemic barriers, along with training community service providers about ASD to potentially enhance participation.

239 **213.239** How Should We Talk about Obesity and Weight-Related Topics with Children with Autism Spectrum Disorders and Their Families?

*A. C. McPherson[1], **P. Jachyra**[2], C. Petta[1], S. Cosgrove[1], L. Chen[1], L. Capano[3], L. Moltisanti[4], T. J. Knibbe[5] and E. Anagnostou[4], (1)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Research, Abilities Centre, Whitby, ON, Canada*

Background: Obesity is a global health concern and can significantly impact the physical and psycho-social health of children. Children with Autism Spectrum Disorder (ASD) appear to be at a higher risk of having obesity than their typically developing peers. Although it has been recommended that health care providers (HCPs) speak to families about the potential health risks of unhealthy weight in ASD, no previous research has explored exactly how HCPs communicate with children with ASD and their families about this topic.

Objectives: To explore the experiences of children with ASD, their families and HCPs when discussing weight-related topics in healthcare consultations.

Methods: Individual, in-depth qualitative interviews were conducted with children with ASD aged 10-18 years with verbal fluency who were attending a tertiary psycho-pharmacology clinic and whose Body Mass Index was greater than the 85th percentile. Their parents were also invited to take part in a separate interview, as were all HCPs who worked in the clinic. Thematic analysis using an interpretive phenomenological approach was used to analyze the verbatim transcripts. Themes were analyzed and discussed by the whole team comprising multi-disciplinary HCPs, researchers and a parent of two children with ASD.

Results: Eight children with ASD, eight parents, and five HCPs were interviewed. Three main themes were identified: 1) Layers of complexity: Weight and health issues were complicated by a combination of medication side-effects, social dynamics within the home, and overall quality of life considerations. Narratives of 'the lazy child' and 'non-compliant parent' were strongly rejected; 2) Uncertainties of communication: Clinicians were often hesitant to start weight-related conversations when families came to see them for other issues. Others worried what impact such a discussion would have on the therapeutic relationship with the families. Parents wanted HCPs to raise the topic early, but were frustrated when realistic solutions were not offered; 3) Wellness over weight: Parents, children and HCPs all identified a need to move from predominantly focusing on a child's weight, and instead promoting overall wellness throughout the life course. Overall recommendations included:

Acknowledging the complexity of the situation; Engaging child in the discussion where possible; Using clear visuals and examples; Establishing a trusting relationship with the family; Using a strengths-based approach.

Conclusions: Children, caregivers and HCPs all recognized the potential short and long-term health risks of overweight/obesity, and identified a need to work collaboratively to positively impact the health status of children. Tools are needed to help HCPs foster positive conversations about weight-related topics and lifelong wellness.

240 **213.240** Physical Health of Autistic Adults

E. Weir, *S. Baron-Cohen and C. Allison, Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

Currently, there are very few large-scale studies of physical health of autistic adults, despite evidence that autistic individuals have increased risk of premature mortality (Hirvikoski et al 2016; Pickett et al 2006). Previous research has found a higher health burden among autistic individuals in general, and specifically for neurological, psychiatric, gastrointestinal, muscular, metabolic, sleep, immune, and endocrine conditions (Croen et al 2015; Davignon et al 2018; Diallo et al 2017; Kohane et al 2012). In addition, it has been suggested that autistic females may be at even higher risk for medical comorbidities than autistic males (Croen et al 2015). Unfortunately, nearly all existing studies fail to sample autistic adults over the age of 35 years.

Objectives:

To identify common physical health comorbidities of autistic adults over the age of 35, and to determine if a sex bias exists regarding physical health conditions within this population.

Methods:

We developed an anonymous, online physical health survey via Qualtrics that inquired about demographics, lifestyle choices/ daily habits, personal medical history, and family medical history for first-degree biological relatives. As the survey attempted to be comprehensive regarding physical health conditions, it contained 512 questions on over 161 medical conditions and lifestyle choices, though it used a tiered structure to avoid survey fatigue. The survey was administered to individuals over the age of 16 years and individuals were asked to self-report any previous autism diagnosis. The AQ-10 was administered to individuals who did not report an autism diagnosis (henceforth 'controls') and individuals with an AQ score ≥6 were excluded. Participants included n=642 autistic individuals and n=361 controls, comprising a total of n=1,003 individuals. The mean age across both groups was approximately 43 years and there was a strong bias towards females, UK residents, and white individuals. Recruitment is ongoing, with efforts to recruit under-sampled demographics.

Results:

We conducted sex-stratified Fisher's exact tests to determine the prevalence of four non-communicable diseases identified by the WHO as accounting for nearly 70% of worldwide mortality (cancer, cardiovascular conditions, respiratory conditions, diabetes). Autistic females were significantly more likely to have respiratory conditions (OR: 1.92; p-value: 0.0015; FDR: 0.0059), with additional trends toward significance for both diabetes (OR: 1.65; p-value: 0.086; FDR: 0.114) and cardiovascular conditions (OR: 1.47; p-value: 0.060; FDR: 0.114), as compared with control females.

Conclusions:

The results suggest that autistic females may be at greater risk of non-communicable diseases than others, particularly for respiratory conditions. These results confirm previous findings; however, it is essential to conduct additional studies in larger samples and with more representative populations. As we are still recruiting participants for this study, we hope to recruit a total sample size of 4,200 individuals, with a greater number of controls in particular.

241 **213.241** Predicting Anxiety from Developmental Trajectories of Temperament in Children at Risk for Autism Spectrum Disorder: The Role of Reactivity and Regulation

M. Ersoy[1], *T. Charman*[2], *G. Pasco*[3], *E. Carr*[4], *M. H. Johnson*[5], *E. J. Jones*[6] *and &. the BASIS Team*[7], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK, London, United Kingdom of Great Britain and Northern Ireland, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Biostatistics & Health Informatics, King's College London, London, United Kingdom, (5)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (6)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (7)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: The mechanisms underlying heightened levels of co-occurring anxiety in children and adolescents with ASD have been poorly understood. Evidence suggests that interplay between temperamental reactivity (behavioural inhibition; BI) and regulation (effortful control; EC) in the early years of life plays a substantial role in anxiety problems in the general population. Determining whether anxiety traits in ASD are underpinned by the same developmental mechanisms in the context of a cohort at familial risk for ASD as anxiety in the general population is important because it may impact on appropriate treatment strategies.

Objectives: To investigate this, we used structural equation modelling to (1) assess whether higher levels of BI predicts anxiety; (2) examine how BI and EC interrelate over the first two years of life and how this interrelation associates with later anxiety and ASD (Figure 1); also we used mediation analyses to (4) probe the relationship between BI, EC (24 months), and later anxiety/ASD (36 months).

Methods: The sample in this study includes 116 high-risk (due to having an older sibling with ASD) and 27 low-risk (due to having no family members with ASD) children. Parent-report measures used to measure temperament (9, 15 and 24 months), anxiety and ASD traits (36 months).

Results: Successful EC at 15 months was associated with lower levels of BI at 24 months and both lower levels of BI and higher levels of EC at 24 months were related to less anxiety as well as ASD traits at 36 months (Figure 1). Exploratory mediation analyses also showed that BI was more strongly associated with anxiety whereas EC more strongly related to ASD symptoms.

Conclusions: The findings suggest that BI may be an early predictor of later anxiety in children at high and low risk of ASD, and that lower levels of EC in children who later develop ASD may contribute to the higher expression of anxiety within this population.

242 **213.242** Predicting Response to Sleep Aids Using Genetic and Comorbidity Data

***L. Brueggeman**, N. R. Pottschmidt and J. J. Michaelson, Psychiatry, University of Iowa, Iowa City, IA*

Background:

Individuals with autism spectrum disorder (ASD) are significantly more likely to endorse challenges with sleep than their peers. In the setting of ASD, sleep has been found to modulate numerous other comorbidities, such as causing flares in aggressivity and anxiety. The symptom-burden of individuals with ASD and the challenges for caretakers can increase significantly if relief from sleep challenges is not found. Despite our increasing understanding of medical factors influencing sleep in ASD, a recent analysis was could only explain~19% of the variance in sleep dysfunction using environmental and medical comorbidity factors. Additionally, while many studies incorporate drug-usage features, to our knowledge, no study has modeled risk factors influencing sleep-associated drug response.

Objectives:

To begin to address these shortcomings, we (1) estimated the heritability of sleep dysfunction in ASD, and (2) performed a comorbidity analysis of sleep-associated drug-response.

Methods:

The foundation of this proposal is an unpublished dataset we generated by re-contacting 5,686 families enrolled in the SPARK genetic study of ASD. SPARK is the largest study of its kind, with whole exome sequencing, genotypes, and medical comorbidity data recently released (November 2018) on over 27,000 individuals. Our unpublished dataset expands the SPARK medical comorbidity data to include quantitative measure of sleep dysfunction (CSHQ; children's sleep habits questionnaire) and questions regarding drug-response to five major classes of drugs used to treat sleep dysfunction in ASD (melatonin, antihistamines, non-benzodiazepines, antidepressants, PM-variant over the counter (OTC) medicines).

Results:

Within our dataset, ~50% of individuals reported sleeping issues, with a further 14% not finding relief of their sleep symptoms through any medicines they tried. Interestingly, we found that melatonin and antidepressant sleep-associated drug response could be significantly modeled using medical comorbidity data (P < 5.6E-06 & 4.4E-02, respectively). These outcomes were influenced by a range of comorbid diagnoses, such as schizophrenia, intellectual disability, and blindness. Through modeling sleep dysfunction, we found a significant SNP-based heritability for the CSHQ score in our cohort (h2 = 0.26; S.E. = 0.15), suggesting that polygenic, common variant risk influences sleep dysfunction in ASD.

Conclusions:

From our analysis of the largest genetic sleep cohort of ASD to date, we find significant evidence for the SNP-based heritability of sleep traits in ASD. Further, by modeling the success of leading therapeutic options for sleep dysfunction in ASD, we gain valuable insights into the ideal medical profile of individuals taking either melatonin or antidepressants to alleviate their sleeping issues. Going forward, this dataset will be used to model the polygenic risk profiles of traits influencing sleep dysfunction and drug response, bringing a novel genetic-based approach to comorbidity analyses. These findings advance our understanding of the etiology of sleep dysfunction in ASD, and provide an early glimpse of factors which could be leveraged in a personalized-medicine treatment strategy for sleep dysfunction.

243 **213.243** Predictors of Psychiatric Hospital Readmission for Children and Adolescents with Autism Spectrum Disorder

***G. Righi**[1], E. Appleton[2], M. Trevino[2], K. Pedersen[3] and M. Siegel[4], (1)Department of Psychiatry and Human Behavior, The Warren Alpert Medical School of Brown University, Providence, RI, (2)Bradley Hospital, Riverside, RI, (3)Department of Psychiatry, Maine Medical Center, Portland, ME, (4)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

Background:

Previous research has shown that children and adolescents with ASD have higher rates of inpatient psychiatric hospitalizations than children with intellectual disability or other psychiatric diagnoses, and youth with ASD have longer psychiatric hospital stays on average. Though recent studies suggest that specialized inpatient units may produce positive treatment outcomes for serious behavioral problems in children and adolescents with ASD, readmissions remain a problem and contribute to the ongoing shortage of adequate psychiatric beds for this population.

Objectives:

To examine the demographic and clinical predictors of short-term hospital readmissions after an inpatient stay in a specialized inpatient psychiatry unit.

Methods:

Participants were selected from the Autism Inpatient Collection (AIC): a multi-site study enrolling children and adolescents admitted to six specialized psychiatric inpatient units. Data include demographic information, medical and psychiatric histories, parent rating scales at time of admission, discharge, and 2 months after discharge, direct assessments performed on the participants during stay, and repeated measures for those who are readmitted. The sample (n = 236; 79% male; mean age = 12.9) was divided to compare differences between participants who were re-hospitalized within 2 months of discharge(n = 59) and those who were not (n = 177). A multiple logistic regression model was applied to examine the relative contribution of different demographic and clinical factors to the likelihood of being readmitted.

Results:

No differences were found among the demographic characteristics of the two groups (age, gender, IQ, minimally verbal status, adaptive functioning, severity of autism symptoms, caregivers' marital status, place of residence). Re-hospitalized participants had significantly more lifetime psychiatric hospitalizations (t (226) = 3.18, p = 0.002). At time of discharge, re-hospitalized participants had higher ABC-Irritability scores (t(198) = 1.9, p = 0.05) and ABC-Hyperactivity scores (t(195) = 2.1, p = 0.047). No differences were found in the type of psychiatric diagnoses given at discharge, nor number of psychotropic medications, but re-hospitalized participants had more psychiatric diagnoses overall (t(234) = 2.6, p = 0.01). A logistic regression model revealed that the total number of psychiatric diagnoses at discharge (OR = 1.66, p = 0.013) and previous psychiatric hospital admissions (OR = 1.15 , p = 0.014) independently predicted the likelihood of being re-hospitalized within 2 months of discharge.

Conclusions:

Results indicate that approximately 25% of participants admitted to one of six specialized inpatient psychiatry units across the country were re-hospitalized within 2 months of discharge. Re-hospitalized participants had a higher number of lifetime psychiatric hospitalizations, more

psychiatric diagnoses at discharge, and higher irritability and hyperactivity scores at discharge. An improved understanding of patients at risk for short-term readmissions could help guide providers to better individualize plans for discharge and follow-up care, and, in turn, lead to a reduction in short-term readmissions. Further research is needed to better understand the needs of this subset of individuals and how to promote improved outcomes.

244 **213.244** Psychiatric Comorbidities in Children with Autism Spectrum Disorder and Intellectual Disability

H. R. Denyer[1], *A. C. Watkins*[1], *M. Erwood*[1], *J. Wolstencroft*[2], *R. Srinivasan*[3], *I. D. Imagine*[1] *and D. H. Skuse*[4], *(1)UCL GOS Institute of Child Health, London, United Kingdom, (2)UCL GOS ICH, London, United Kingdom, (3)UCL GOS ICH, London, United Kingdom of Great Britain and Northern Ireland, (4)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Background: Intellectual disability (ID) is characterised by significant limitations in cognitive functioning, adaptive behaviour, and with significant behavioural difficulties or mental health problems. IMAGINE-ID is a UK national cohort study exploring psychiatric risk in children with ID of known genetic aetiology (CNV and SNV).
Objectives: IMAGINE-ID is a genotype-first study of psychiatric risk. We conducted deep-phenotyping, subsequent to the identification of pathogenic CNV or SNV as a cause of developmental delay. Our objective was to assess the prevalence of ASD in an ID cohort identified through NHS genotyping, and to contrast psychiatric comorbidities in those with and without ASD.

Methods: 2,381 children with ID of known genetic aetiology, confirmed by microarray, have been recruited from UK Regional Genetic Centres. Caregivers completed a standardised psychiatric and developmental history interview (the Development and Wellbeing Assessment - DAWBA). The DAWBA generates probability scores for DSM-5 diagnoses, which are then validated by clinical review. Additional measures include the Strengths and Difficulties Questionnaire (SDQ; child emotional and behavioural adjustment); and the Everyday Feelings Questionnaire (EFQ; parental emotional wellbeing). All measures have been used in national UK studies of child mental health. 1,850 assessments have been completed and 1,049 have been rated by clinicians to date. Mean age of cohort was 9.21 (SD 3.87, range 4-18 years).

Results: Overall, 39% met criteria for ASD, with no significant differences in age, mental age or language ability between children with and without ASD. There was a significant gender bias in children with ASD than without (males predominated; 62.5%, $p<0.01$). Children with ASD were significantly more likely to meet DSM-5 criteria for any additional psychiatric disorder than children without ASD (44% vs 27%, $p<.001$): with a significantly higher prevalence of Attention-Deficit/Hyperactivity Disorder (ADHD; 28% vs 17%, $p<0.001$), Oppositional Defiant Disorder (ODD; 17% vs 5%, $p<0.001$), Anxiety Disorders (15% vs 8%, $p<0.001$) and Tic Disorders (5% vs 1.7%, $p<0.005$). There were no significant prevalence differences between the groups in terms of Obsessive Compulsive Disorder, Depression or Conduct Disorder.

Within-group comparisons on the basis of SDQ total scores showed that emotional and behavioural problems were significantly more severe in children with ASD than those without ($p<0.001$). A comparison with national UK population data showed that 41% of those with ASD had scores above the 95th centile in total SDQ score. EFQ scores were significantly higher in caregivers of children with ASD ($p<0.001$) than in families whose child had ID alone.

Conclusions: A high proportion of children with ID of genetic aetiology meet DSM-5 criteria for an ASD, irrespective of the specific CNV or SNV. Compared with children whose ID is not associated with ASD, and who are of equivalent mental age, there is an excess of specific psychiatric comorbidities, including ADHD, ODD, Anxiety Disorders and Tic Disorders. Parents of children with ID of known genetic origin that is associated with ASD have an enhanced risk of stress-related disorders of mood and feelings, and their parents have an enhanced risk of stress-related disorders of mood and feelings.

245 **213.245** Psychopathological Comorbidity in Children with Autism Spectrum Disorder: The Executive Function Mediator

Q. Chen, *B. Wan and Y. Jin, Sun Yat-sen University, Guangzhou, China*

Background: Autism spectrum disorder (ASD) presents high prevalence of psychiatric disorders which worsen ASD core symptoms, and these disorders are associated with different components of executive function (EF). Previous studies articulate just one or two commodities in children with ASD. However, it is unclear which comorbidities are related to worsening ASD core symptoms in the system of various psychiatric disorders and the basis of the EF components remains unknown for these relationships.
Objectives: The study aimed to identify which psychiatric disorders worsen ASD core symptoms and examine the role of daily EF in comorbid psychopathology in children with ASD.

Methods: The present study analyzed 100 children with ASD (79 males, age: M=10.6 SD=1.6 years) and 180 typically developing (TD) children (94 males, age: M=10.4 SD=1.3 years). Achenbach's Child Behavior Checklist (CBCL), Behavior Rating Inventory of Executive Function (BRIEF) and Social Responsiveness Scale (SRS) were applied for assessing parent-reported comorbid psychopathologies (affective disorder, anxiety disorder, somatic disorder, attention deficit/hyperactive disorder-ADHD, oppositional defiant disorder-ODD, conduct disorder-CD), EF (including two systems: behavioral regulation index, BRI; metacognition index, MI), and ASD core symptoms (social interaction and communication, SIC; repetitive restricted behaviors; RRB), respectively.

Results: The present study found that there were three psychopathological comorbidities (affective disorder, anxiety disorder, and ADHD) independently related to worsening ASD core symptoms, and observed full mediating effect of different EF systems in multivariate models. After controlling for the two other disorder domains, 1) affective disorder damaging SIC related to MI (indirect effect size=0.31, 95%CI= 0.11, 0.54); 2) anxiety disorder was mediated by BRI to worsen SIC (indirect effect size=0.42, 95%= 0.21, 0.69) and RRB (indirect effect size=0.42, 95%CI=0.21, 0.67); 3) ADHD was mediated by both EF systems (BRI, indirect effect size=0.26, 95%CI=0.09, 0.48; MI, indirect effect size=0.21, 95%CI=0.06, 0.40) to aggravate SIC and by BRI (indirect effect size=0.39, 95%CI=0.18, 0.65) to deteriorate RRB. In the meantime, the relationship between pathopsychological symptoms and the core symptoms of ASD was not full mediated by EF in TD children.

Conclusions: Our findings suggest that comorbid with affective disorder, anxiety disorder, and/or ADHD will worsen ASD core symptoms, in which association different EF components play a diverse mediating effect. Our study sheds light on the behavioral mechanism underlying to comorbid psychology in children with ASD.

246 **213.246** Relationships Among Restricted Interests and Repetitive Behaviors, Internalizing and Externalizing Symptoms, and Oral Language in ASD

D. M. Truong[1], *S. S. Mire*[2], *S. D. Hein*[3], *R. P. Goin-Kochel*[4], *M. Keller-Margulis*[3] *and H. Yoshida*[5], *(1)Psychological, Health & Learning Sciences, University of Houston, Houston, TX, (2)Psychological, Health, & Learning Sciences, University of Houston, Houston, TX, (3)Psychological Health and Learning Sciences, University of Houston, Houston, TX, (4)Baylor College of Medicine, Houston, TX, (5)Psychology, University of Houston, Houston, TX*

Background: Up to 72% of children with autism spectrum disorder (ASD) have at least one comorbid internalizing (e.g., anxiety) or externalizing (e.g., ADHD) disorder. Varying oral language abilities are related to different comorbid psychiatric symptoms. However, little is known about how oral language relates to restricted interests and repetitive behaviors (RRBs) and comorbid internalizing or externalizing symptoms. Even less is known about how different *types* of RRBs (i.e., "insistence on sameness" [IS] and "repetitive and sensorimotor behaviors" [RSM]) impact symptom manifestation. Understanding interactions between these RRBs and comorbid internalizing and externalizing symptoms may elucidate clinical presentation and inform more effective ASD interventions.

Objectives: To examine how oral language affects relationships between specific RRBs, internalizing and externalizing symptoms.

Methods: Data were analyzed from a subsample of children in Phase 1 Simons Variations in Individuals Project (Simons VIP) (52% male; ages 6-18 years old) who had 16p11.2 deletions/duplications or 1q21.1 deletions/duplications + ASD (*N*=90). Two types of RRBs (RSM, IS) were measured using the *Behavior and Sensory Interests Questionnaire* (BSI). Oral language was measured via the *Comprehensive Assessment of Spoken Language* (CASL), and caregiver-reported internalizing (INT) and externalizing (EXT) symptoms were measured with the *Child Behavior Checklist* (CBCL/6-18). CASL oral language ability was examined as a potential moderator of RSM and IS with INT and EXT, respectively.

Results: Overall, BSI RSM scores were in the higher range (*M*=9.66, *SD*=8.62), while BSI IS scores were in the lower range (*M*=5.50, *SD*=6.20) compared to scores in the validation study. Mean CASL core composite standard scores were in the lower borderline range (*M*=74.19, *SD*=17.21). Mean CBCL T-scores were in the average range for INT (*M*=56.45, *SD*=10.78) and elevated for EXT (*M*=61.26, *SD*=10.60). Four multiple regression models were estimated using BSI scores (IS, RSM) as predictors of INT and EXT scores, respectively. CASL scores were included as potential moderators. In the two multiple regression models for INT scores, results were significant for both types of RRBs: RSM: R^2=.100, F (3,86)=3.19, p=.03; IS: R^2=.09, F (3,86)=2.89, p=.04. For EXT scores, regression model results were not significant. RSM predicted INT (β=.29, p<.01) and EXT (β=.23, p=.04). IS scores predicted INT (β=.27, p<.01) but not EXT (β=.21, p=.06). CASL scores did not moderate the relations of RSM and IS with EXT and INT, respectively.

Conclusions: Findings revealed that both types of RRBs predicted internalizing symptoms in children with ASD. Children with high RSM had more internalizing *and* externalizing symptoms; however, IS predicted only internalizing symptoms. Contrary to our hypothesis, children's oral language ability did not moderate the association between RRBs and either internalizing or externalizing symptoms. It is possible that this relates to the overall low oral language ability in our relatively small sample. However, findings are nuanced, and the forthcoming examination of specific types of internalizing (anxious/depressed, withdrawn, somatic complaints) and externalizing symptoms (rule-breaking, aggressive behaviors) or of facets (index scores) of oral language ability will provide further information about relationships between these domains. Additional analyses will also examine these relationships between the duplication+ASD and deletion+ASD groups.

247 **213.247** Self-Injury in Autism: Predictors, Perceptions, and Links to Suicidality

R. Moseley[1], *N. J. Gregory*[2], *P. Smith*[3], *C. Allison*[4] *and S. Baron-Cohen*[4], *(1)Bournemouth University, Poole, United Kingdom, (2)Department of Psychology, Bournemouth University, Poole, United Kingdom, (3)University of Cambridge, Cambridge, United Kingdom, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

Self-injurious behaviours (SIB), such as cutting or burning, are closely related to mental ill-health and suicidality [1]. One preliminary study (Maddox et al., 2017) suggests that autistic people without intellectual impairment, the group who are at highest risk of suicidality, are a high-risk group for self-injury, too. These individuals engage in SIB in a qualitatively different way than autistic people with intellectual impairment, a way that shares many features in common with non-autistic people. Unfortunately, despite the links between SIB and suicidality in the non-autistic population and the increased risk of both in autistic people, understanding of self-injury and its relation to suicidality in this subgroup of the spectrum remains very limited.

Objectives:

We attempted to expand on this previous work by a) corroborating the previous description of autistic SIB with a bigger sample; b) exploring predictive factors for self-injury, and factors predictive of self-injury for specific functional goals; c) qualitatively exploring how autistic people perceive their self-injury and what helps them control or overcome it; d) and, in a second follow-up study, exploring relationships between self-injury and suicide ideation or attempts.

Methods:

One hundred and three (n = 103) autistic participants were recruited for this online study from the Cambridge Autism Research Database (CARD) and from advertising on social media. Participants completed the Non-Suicidal Self-Injury Assessment Tool (NSSI-AT[5]) and were classified as current, historic or non-self-harmers. In a theory-driven approach, a number of variables were of interest led by the literature on SIB in autistic and non-autistic people, and therefore participants completed measures of alexithymia, anxiety, depression, mentalizing, autistic traits, and sensory experiences. In a follow-up study we asked participants to complete the Suicide Behaviours Questionnaire-Revised.

Results:

Our data corroborated many of the features and reasons for SIB as described in Maddox et al., but multinomial regression furthermore revealed that alexithymia and sensory-sensitivity significantly predicted the self-injury status of participants. Alexithymia was the only variable to predict SIB for any of the functional roles delineated by the NSSI-AT, specifically predicting SIB engaged in for regulating high energy states (e.g. agitation, anger) and communicative purposes. An interesting dichotomy emerged in the qualitative data between those distressed by their SIB and those who viewed it methodically as a tool (for instance, "to achieve homeostasis"). However, whereas current and historic self-harmers were significantly more likely to endorse statements indicating suicide ideation and attempts, there was no relationship between the distress participants felt at self-harming and their responses to the suicidality questionnaire.

Conclusions:

Our findings highlight certain features, such as alexithymia and sensory sensitivity, as particularly notable for clinicians who might have concerns about self-injury in their autistic patients. A relationship between SIB and suicide ideation and attempts exists regardless of how autistic people feel about their self-injury, corroborating the idea of self-injury as a 'time-invariant' risk factor or 'gateway' for suicidality'.

248 **213.248** Sensory Sensitivity and Intolerance of Uncertainty Separately Influence Anxiety in Adults with Autism Spectrum Disorders

N. C. Russell[1], *D. N. Top*[1], *C. A. Larson*[2], *J. Rodgers*[3], *M. Freeston*[4] *and M. South*[5], *(1)Brigham Young University, Provo, UT, (2)Neuroscience, Brigham Young University, Provo, UT, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Newcastle University, Newcastle upon Tyne, United Kingdom, (5)Psychology & Neuroscience, Brigham Young University, Provo, UT*

Background: Anxiety affects at least 50% of adults with autism spectrum disorders (ASD) and can lead to significant impairment in day-to-day life for these individuals and their families. In addition, an increase in ASD traits is linked with an increase in anxiety. Research has sought to elucidate the mechanisms by which ASD traits influence an individual's anxiety in order to provide context and support for interventions. Two factors that have emerged as potentially influential are sensory sensitivities (SS) and intolerance of uncertainty (IU). SS can make the natural environment of an individual with ASD more challenging to experience and can even result in physical pain. IU can be distressing and lead to negative evaluation as well as influence restricted/repetitive behaviors. While both SS and IU have been shown to influence anxiety, research has not yet looked at their influence together in an adult ASD population.

Objectives: We examined the influence of SS and IU on anxiety in adults with ASD using structural equation modeling (SEM). We assessed whether SS and IU can exert this influence alone and what level of influence they have.

Methods: A dimensional sample consisting of 214 typically developing adults and 71 adults with a confirmed diagnosis of ASD completed self-report questionnaires. ASD traits were identified using the Autism Spectrum Quotient (AQ), IU was identified using the Intolerance of Uncertainty Scale – Short Form (IUS-12), sensory sensitivity was assessed using the Adolescent/Adult Sensory Profile (AASP), and anxiety was identified using the Penn State Worry Questionnaire (PSWQ).

Results: The first SEM analysis supported the hypothesis that SS and IU play a mechanistic role in the relationship between ASD traits and anxiety. The relationship between ASD traits and anxiety was significant when modeled individually but this relationship was eliminated by adding SS and IU as mediators (explaining 33.6% and 54.3% of the influence, respectively). Neither mediated the relationship when included individually. The second SEM analysis attempted to model the influence of SS, IU, and ASD traits on anxiety. All factor loadings were in the expected direction and there was converging evidence for excellent model fit. This model suggested that SS and ASD traits largely operate on anxiety via IU with SS still having a direct influence on anxiety. Importantly, including SS and IU in the model removed the direct influence of ASD traits on anxiety. Finally, replicating previous research that looked at whether anxiety itself mediates the influence of IU on SS, but with an adult population, showed a small influence of anxiety which was more pronounced in an ASD-only population.

Conclusions: The influence of ASD traits on anxiety operates via IU. Both SS and IU are necessary to explain this influence. Our model suggests that both SS and IU largely explain increases in anxiety and that SS functions both independently and through IU. This provides further evidence for the importance of addressing these specific challenges in order to reduce anxiety and the impairment associated with it.

249 **213.249** Sleep Dysregulation and Circadian Electrodermal Activity in Children with Autism Spectrum Disorder

P. L. H. Chong, *E. A. Abel, R. Pao and A. J. Schwichtenberg, Purdue University, West Lafayette, IN*

Background: Up to 80% of children with an autism spectrum disorder (ASD) experience sleep dysregulation. A breadth of research documents the behavioral correlates of sleep dysregulation—including increased ASD symptoms, aggression, and other challenging behaviors (e.g., Goldman et al., 2011). These associations are documented in both home and treatment settings (e.g., Abel et al., 2018). However, the physiological correlates of sleep dysregulation are poorly understood and likely to contribute to daytime behavior problems and potentially treatment progress.

Objectives: The goal of the present study is to understand the physiological correlates of sleep dysregulation in ASD by assessing child sleep and electrodermal activity during daytime center-based treatment.

Methods: Thirteen children (mean age of 6.19 years, *SD* = 2.24) with a medical diagnosis of ASD participated in this study for one treatment week. Children received treatment in an applied behavior analysis center for up to 8 hours per day from roughly 09:00 to 17:00. Each child wore an Empatica E4 multi-sensor during treatment, resulting in over 10,000 minutes of electrodermal activity (EDA) data. Skin conductance responses (SCRs) were extracted from the EDA data following guidelines from Kleckner et al. (2017). Actigraphy was used to measure sleep for five consecutive 24-hour periods (which corresponded with the EDA data collection). Each child's sleep was classified as either regulated (n = 7) or dysregulated (n = 8) based on the following criteria: (1) slept less than the American Academy of Sleep Medicine recommendations for their age, (2) woke for more than an hour on a least two nights, and/or (3) had morning rise or bedtimes that varied by more than two hours. Child ASD symptoms was indexed with the Social Communication Questionnaire (SCQ).

Results: A series of regression analyses were conducted across the regulated and dysregulated sleep groups, predicting average SCRs per minute across each treatment hour. Children in the dysregulated sleep group had fewer SCRs as the treatment day progressed (Figure 1). When the covariates of child ASD symptoms, age, and maternal education were considered, these associations were attenuated and no longer significant. Children in the dysregulated sleep group were older and tended to have more ASD symptoms when compared to the regulated sleep group (Table 1). Due to small sample size, we were unable to fully detect how these covariates influence the relations between sleep and SCRs. However, we were able to document distinct circadian SCR patterns for a subgroup of children with ASD.

Conclusions: SCRs often reflect sympathetic arousal to environmental stimuli. Fewer SCRs may indicate less engagement with the environment (as indexed by lower arousal). This preliminary study requires replication before treatment or clinical recommendations can be drawn. However, our results clearly suggest that SCRs follow a circadian or daily cycle. The roles of child age, ASD symptoms, and sleep warrant further investigation to understand their relations with arousal and ultimately daytime behaviors during treatment.

250 **213.250** Sluggish Cognitive Tempo Profiles Among Young Adults with ASD

***A. M. Brewe**, N. N. Capriola and S. W. White, Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Sluggish cognitive tempo (SCT) refers to a set of behavioral and cognitive symptoms characterized by a sluggish activity level, slow processing, daydreaming, and mental fogginess (Becker et al., 2016). Despite similarities between SCT and attention-deficit/hyperactivity disorder (ADHD), research has shown SCT to be distinct from ADHD with its own behavioral phenotype and independently associated psychiatric comorbidities (Barkley, 2012; Becker et al., 2017; Reinvall et al., 2017). Despite the high comorbidity of ADHD for individuals with autism spectrum disorder (ASD), limited research has explored SCT symptomology in an ASD sample.
Objectives: The current study aimed to characterize the relationship between SCT and ADHD in an ASD sample. We also sought to determine if SCT symptoms are independently associated with co-occurring symptoms of anxiety and depression in adults with ASD, controlling for ADHD symptoms.

Methods: Participants included 30 young adults with ASD (Mean age (in years) =20.10, SD =2.00). Participants' parents completed the Adult Behavior Checklist (ABCL; Achenbach & Rescorla, 2003), a parent-report measure of behavioral, emotional, and social problems for adults. T-scores for the SCT, ADHD, anxiety, and depression scales were used as measures of participants' psychiatric symptoms.

Results: Descriptively, there was variability in participants' SCT scores, with 20 percent of participants meeting borderline clinical cut-offs for SCT symptoms and an additional 40 percent meeting for clinically significant cut-offs. Participants' ADHD and SCT T-scores were significantly correlated, $r = .689$, $p < .001$. Partial correlations revealed that participants' SCT scores were significantly correlated with depression symptoms when controlling for ADHD symptomology, $r = .495$, $p < .010$. However, participants' SCT scores were not significantly correlated with anxiety symptoms when controlling for ADHD symptomology, $r = .190$, $p > .050$.

Conclusions: Results suggest that individuals with ASD experience a range of SCT symptoms, which are strongly positively related to ADHD symptoms. Despite this strong association with ADHD, SCT symptomology appears independently related to depressive symptoms, with adults with ASD and high SCT symptoms experiencing more depressive symptoms. Given the shared behavioral symptoms between SCT and depression (e.g. lack of motivation, cognitive dulling, fogginess) and previous studies finding SCT and depression to be related in non-ASD samples (Becker et al., 2016), SCT and depression may be uniformly related and not specific to ASD. These findings also support the theory that SCT may be its own construct distinct from ADHD. However, SCT was not independently associated with anxiety symptoms, contrary to findings on children and adolescents from the only other study to analyze SCT in an ASD sample (Reinvall et al., 2017). Additional research with a larger sample size is necessary to further distinguish SCT as an independent behavioral construct related to ASD and identify if SCT independently affects functioning among young adults with ASD. Determining how SCT symptomology impacts the behavioral and emotional ASD profile could lead to better understanding of the disorder and improved efficacy of interventions to maximize positive outcomes for this population.

251 **213.251** Social Competence Predicts Anxiety Symptoms in Girls but Not Boys with ASD

***N. M. Kauppi**, H. Aime, T. Boucher and G. Iarocci, Simon Fraser University, Burnaby, BC, Canada*

Background: Children and adolescents with ASD have an estimated 39.6% prevalence rate of anxiety disorders (van Steensel, Bogels, & Perrin, 2011), much higher than the general population. Poor social functioning is related to increased anxiety in youth with and without ASD (Kerns et al., 2015; Settipani & Kendall, 2013). Recently, Johnston and Iarocci (2017) found that more internalizing symptoms (i.e., depression and generalized anxiety) were related to lower social competence in youth with and without ASD; however, gender differences were not possible to examine. Girls are more socially competent and have higher anxiety than boys (Crocetti et al., 2015; Dunsmore et al., 2008). Gender differences in social competence and anxiety in ASD may be especially helpful in understanding the difference in symptom profile between boys and girls with ASD
Objectives: The objective of the current study was to examine the relations between anxiety symptoms and social competence in girls, as compared to boys, with and without ASD.

Methods: Four hundred and eighty-four youth (ages 6-14), all with IQ>80, and their parents were included in this study. Parents completed the Behaviour Assessment System for Children (BASC-2; Kamphaus & Reynolds, 2004) and the Multidimensional Social Competence Scale (MSCS; Yager & Iarocci, 2013). The BASC provides an anxiety T-score and the MSCS provides an overall rating of social competence. Four groups were established using gender and diagnostic status: TD girls (n=108, mean age=9.41, mean IQ=113.07), ASD girls (n=42, mean age=9.87, mean IQ=108.45), TD boys (n=153, mean age=9.31, mean IQ=109.4), and ASD boys (n=181, mean age=9.91, mean IQ=104.9).

Results: Separate hierarchical multiple regressions were conducted for ASD and TD groups for each gender, with IQ and age included in the first block, MSCS total score included in the second block, and the anxiety subscale T-score of the BASC-2 as the dependent variable. Significant positive correlations were found between IQ and MSCS scores in girls in both groups (TD: r=.23, p=.007; ASD: r=.381, p=.006), and between age and anxiety T-scores for TD boys (r= .141, p=.042). A significant negative correlation was found between anxiety T-scores and MSCS total scores in girls with ASD (r=-.496, p<.001). No significant prediction was found for IQ, age, or MSCS scores for TD girls, TD boys, or ASD boys. However, the MSCS had significant predictive value for anxiety among girls with ASD ($\Delta R2=.294$, p<.001).

Conclusions: The results are consistent with previous research indicating that poorer social competence predicts greater anxiety symptoms in youth with ASD; however, this effect was only found in girls with ASD. These results indicate that poorer social competence predicts greater anxiety symptoms in girls with ASD, but not boys with ASD or typically developing youth. This suggests there may be important differences between these groups, such that deficits in social competence may have a greater effect on the mental health of girls with ASD compared to their same-gender TD peers and boys with and without ASD. Implications for future research will be discussed.

252 **213.252** Suicidality in Adults with Autism Spectrum Disorder: The Role of Depression and Alexithymia

***A. P. Costa**[1], C. Loor[2] and G. Steffgen[3], (1)University of Luxembourg, Esch sur Alzette, LUXEMBOURG, (2)University of Luxembourg, Esch sur Alzette, Luxembourg, (3)Institute for Health and Behaviour, University of Luxembourg, Luxembourg, Luxembourg*

Background: Individuals with autism spectrum disorder (ASD) have a higher risk of depression and suicidality than individuals without ASD. Alexithymia, a personality construct characterized by a lack of emotional awareness, that is highly linked to depression, is also more prevalent among people with ASD than in the general population. Few studies have so far examined the increased risk of suicidality in people with ASD and none have looked into how alexithymia could be a significant risk factor for suicidality in ASD.

Objectives: The aim of the present study is to explore more closely the relationship between alexithymia, depression, and suicidality in ASD. It is hypothesized that there are higher rates of depression, suicidality, and alexithymia in people with ASD compared to neurotypical adults. Because the risk of suicidality can be explained by high levels of depression and alexithymia in the general population, this is also hypothesized for the group of people with ASD.

Methods: In the present study, 53 adults diagnosed with ASD and a control group of 132 adults without ASD were compared on their self-reported scores on autistic traits (AQ-short), depression (CES-D), suicidality (SBQ-R), and alexithymia (TAS-20). Participants were aged between 18 and 60 years. The ASD group was significantly older (M = 33.75; SD = 11.02) than the control group (M = 29.08; SD = 8.74), $t(183) = -3.04$, $p < .01$ and there were significantly more men than women in the ASD group (21 men, 31 women, 1 other) than in the control group (31 men, 101 women), $\chi^2(2) = 7.72$, $p < .05$.

Results: The results revealed that the ASD group had significantly higher levels of autistic traits [$F(1, 181) = 394.61$, $p < .001$, $\eta_p^2 = .69$], depression [$F(1, 181) = 51.86$, $p < .001$, $\eta_p^2 = .22$], suicidality [$F(1, 181) = 71.51$, $p < .001$, $\eta_p^2 = .28$], and alexithymia [$F(1,181) = 143.44$, $p < .001$, $\eta_p^2 = .44$] than the control group. A hierarchical linear regression analysis including age, gender, autistic traits, depressive symptomatology, and alexithymia also revealed that the severity of autistic traits and depressive symptomatology were significant predictors of suicidality (autistic traits: $\beta = 1.24$, $p < .001$; depression: $\beta = 1.30$, $p < .001$). Furthermore, alexithymia played a moderating role in the relation between autistic traits and suicidality: a significant relation was found between autistic traits and suicidality on participants with high levels of alexithymia [$b = 1.61$, $SE = 0.31$, $p < .001$], but autistic traits were not related to suicidality on participants with low levels of alexithymia [$b = -0.54$, $SE = .45$, $p = .24$].

Conclusions: The present results show that individuals with ASD are vulnerable to suicidal ideation and that the severity of autistic traits, depression, and alexithymia are important factors in the occurrence of suicidal ideation in ASD. Because of the high risk of suicidality in ASD, interventions that take into consideration depression, and particularly alexithymia, could potentially benefit people with ASD.

253 **213.253** The Association between Somatic Comorbidity and ASD Among Discordant Twins

P. Y. Pan[1], *K. Tammimies*[2] *and S. Bolte*[3], *(1)Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background:
Individuals with autism spectrum disorder (ASD) show higher prevalence of co-occurring somatic disorders than the general population, including immune dysregulation, gastrointestinal problems, and neurological problems. The co-existence of somatic problems in ASD is associated with more burden and lower quality of life. In addition, it also suggests the possibility of an underlying genetic and/or environmental perturbation affecting multiple systems that might lead to both somatic disorders and ASD. However, except some specific genetic disorders and the current findings of gene pleiotrophy, there is still little information regarding the relationships between somatic comorbidity and the symptoms of ASD.

Objectives:

This study aimed to use a monozygotic (MZ) twin sample, which has the advantage of well-controlled genetic background, to investigate if somatic comorbidity is involved in the etiological mechanism of ASD symptoms.

Methods:

Seventy-five MZ twin pairs (including 18 twin pairs discordant for ASD diagnosis and 18 typically developed (TD) twin pairs) and 60 dizygotic (DZ) twin pairs with varying autistic traits were selected for analysis in this study. A questionnaire asking past medical history and current physical problems were used to collect the information of the participants' somatic comorbidity. All the physical problems were categorized into infectious diseases, neurological problems, gastrointestinal problems, immunological problems, and cardiovascular diseases. The Social Responsiveness Scale, Second Edition (SRS-2) was used to measure the participants' ASD symptoms. The differences of somatic comorbidity among twins discordant for ASD and TD twins were examined. The somatic problems identified with significant within-pair differences were then tested in relation to autistic traits in both MZ and DZ twin pairs quantitatively discordant for ASD, which was defined as at least 6 points for the intra-pair difference of SRS-2 total score.

Results:

The twins with ASD in discordant MZ have more neurological problems compared to their co-twins and TD twins. However, there are no differences in infectious diseases, gastrointestinal problems, cardiovascular diseases, and immunological problems among MZ twins discordant for ASD and TD twins. For the MZ twins quantitatively discordant for ASD, the intra-pair differences of neurological problems are significantly correlated with the differences of total score of SRS-2 ($r = 0.40$, $p = 0.001$). In addition, with the conditional model for within-pair effect analysis, there is significant association between neurological problems and total score of SRS-2 ($\beta = 11.66$, $p = 0.002$) after adjusting for ADHD and IQ.

Conclusions:

Our findings suggest that neurological problems could be considered as a non-shared environmental factor for MZ twins discordant for ASD symptoms. In addition, organic neuropathy might play a pathogenic role in the development of ASD. However, we did not find association between somatic comorbidity of other physical systems and ASD symptoms in our twin sample. Further population-based studies are warranted to validate our results.

254 **213.254** The Impact of Associated Anxiety Symptoms on Emotion Recognition in Individuals with Autism Spectrum Disorder

B. Oakley[1], *E. J. Jones*[2], *L. Mason*[2], *D. V. Crawley*[1], *J. Ahmad*[1], *H. Meyer-Lindenberg*[3], *D. G. Murphy*[4] *and E. Loth*[1], *(1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)King's College London, London, United Kingdom, (4)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Some autistic individuals experience emotion recognition difficulties, as compared to neurotypical populations. Furthermore, anxiety disorders have also been related to emotion recognition difficulties, potentially due to heightened state arousal in response to some expressions, such as high intensity emotions/threat cues. Despite the high prevalence of anxiety symptoms in autism – over 40-50% - few studies have

examined the impact of co-occurring anxiety on emotion recognition.
Objectives: To investigate the relationship between anxiety symptoms and emotion recognition in autism.

Methods: 612 6-30-year-olds with (*N*=363) and without (*N*=249) Autism Spectrum Disorder (ASD) from the EU-AIMS Longitudinal European Autism Project were included. At Time 1, anxiety symptoms were measured using the Development and Wellbeing Assessment (DAWBA), with a 'high anxiety' cut-off implemented (see Goodman et al., 2010). 105 participants (29%) in the ASD group had high anxiety. Emotion recognition difficulties were assessed using an emotion-matching paradigm (Palermo et al., 2013), whereby participants selected the non-matching expression from an array of three faces, oriented left/right, or front-facing. At Time 2 (~18 months later) anxiety symptoms were re-assessed using the 'emotional symptoms' subscale from the Strengths and Difficulties Questionnaire (SDQ). Concordance between anxiety measures was good (r>0.63, p<2.2e-16). Emotion recognition difficulties were assessed in a basic emotion recognition paradigm using the Karolinska Directed Emotional Faces stimuli, including neutral, positive (e.g. happy) and negative (e.g. angry) expressions. We report effect sizes for Mann-Whitney U tests (r) and Spearman's correlations (r_s).

Results: At Time 1, individuals with ASD and low, compared to high, DAWBA-rated anxiety did not differ on age (effect size r=0.01, p=0.92), nor IQ (effect size r=0.05, p=0.38). A higher proportion of females than males had high anxiety (X^2=5.65, p=0.02, φ=0.12). Individuals with ASD and high anxiety were significantly less accurate at emotion-matching than those with lower anxiety on *front-facing* trials (effect size r=-0.30, p=0.01; Figure 1). In other words, the relationship between anxiety symptoms and emotion recognition – confirmed by simple correlations (r_s=-0.27, p=0.02) - was only present when stimuli were oriented to the front, with direct gaze. At Time 2, higher self-reported anxiety symptoms, according to the SDQ, were also marginally related to basic emotion recognition difficulties, specifically for trials depicting anger (r_s=-0.23, p=0.05), a socially and evolutionarily relevant threat cue. This effect was significant at the p<0.05 threshold but did not survive Bonferroni correction.

Conclusions: We found that co-occurring anxiety symptoms in ASD are related to emotion recognition accuracy for stimuli with direct gaze and displaying threat cues (anger). The ability to recognise and respond to the emotional expressions of others is fundamental for building successful interpersonal relationships. Therefore, our results emphasise that the management of co-occurring anxiety symptoms in ASD is important, not only for enhancing the quality of life of autistic individuals, but also facilitating social functioning and development. Future research should incorporate state arousal measures (e.g. heart rate) to further elucidate how anxiety symptoms modulate reactivity to social stimuli in ASD. This is particularly relevant given that stimuli with direct gaze/threat cues increase physiological responsiveness in neurotypical populations.

255 **213.255** The Impact of Sleep Variability on Sleep Duration and Daytime Behavior in Children on the Autism Spectrum

S. Reimer[1], *T. Winkelman*[1], *A. Naples*[1], *S. Baddam*[2], *C. Canapari*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT, (3)333 Cedar St PO Box 208064, Yale University, New Haven, CT*

Background: Children with autism spectrum disorder (ASD) have sleep difficulties at a rate of 40-80 percent, compared to 25-40 percent of typically developing (TD) children, affecting daytime behavior and quality of life. Sleep difficulties can be measured objectively through actigraphy or polysomnography or through subjective report, with both methods providing comparable accuracy (Baddam et al., 2018). In typical development, sleep duration decreases with increasing age, yet this trajectory is poorly understood in children with autism.
Objectives: To examine relationships among variability of sleep cycle with sleep duration and daytime behavior across development in children with ASD and TD.

Methods: Participants were children aged 7-18 with ASD (*n*=34, Mean IQ=96.3, Mean Age=12.4 years) and TD (*n*=16, Mean IQ=112.0, Mean Age=12.8 years). Parents completed the Yale Developmental Sleep Questionnaire, which asks for the earliest, latest, and usual time of their child's bedtime routine (BR), lights out (LO), and wake time (WT) for the most recent weekdays and weekend. Clinician-administered and parent-reported measures provided information on intellectual function and symptomatology: Differential Ability Scales, Autism Diagnostic Observation Schedule, and Child Behavior Checklist. Children were given variability scores (VS) consisting of the sum of the differences in earliest and latest times for BR, LO and WT, and difference between weekend and weekday usual BR, LO, and WT. Children were placed in either a low variability (LV; VS≤7h, *n*=18: 12 ASD, 6 TD) or high variability (HV; VS> 7h, *n*=32: 22 ASD, 10 TD) variability group. The mean ages and IQs did not significantly differ based on sleep variability. For both ASD and TD children, variability scores were normally distributed.

Results: Consistent with the literature, a negative correlation between sleep duration and age was seen in the TD group (r=0.773, p=0.000). However, this trend was not observed overall in the ASD group (r=0.185, p=0.295). When contrasting LV and HV participants with ASD, the expected developmental pattern was observed among LV ASD participants (r=0.740, p=0.006) but not HV ASD participants (r=0.040, p=0.861). Within the ASD group, parents of children with HV reported significantly less inattention (p=0.052) and hyperactivity (p=0.040) than the LV group.

Conclusions: High and low sleep variation in ASD children were associated with distinct developmental patterns of sleep maturation and different daytime behaviors. These differences were not observed in TD children. Children with ASD and high sleep variation failed to display the expected association between sleep duration and age and, counter to predictions, were less likely to display inattention and hyperactivity. Future studies can build on these findings by using objective measures of sleep such as polysomnography or actigraphy (Hodge et. al., 2012) to further explore the relationship between sleep variability and daytime behaviors.

256 **213.256** The Impacts of SSRI Medication and Comorbid Anxiety on Brain Function in ASD

J. Bartolotti[1], *E. Cook*[2] *and M. W. Mosconi*[3], *(1)Kansas Center for Autism Research and Training, Life Span Institute, University of Kansas, Lawrence, KS, (2)University of Illinos at Chicago, Chicago, IL, (3)Clinical Child Psychology Program, Schiefelbusch Institute for Life Span Studies, University of Kansas, Lawrence, KS*

Background: Resting state functional connectivity of fMRI data identifies co-activated brain networks and is a promising method for defining biologically similar ASD subtypes and new treatment strategies. However, efforts to characterize alterations in functional connectivity among individuals with ASD are hindered by confounding factors that impact brain function and are variably present across individuals, including medication usage and comorbid psychiatric conditions. Quantifying the impacts of known sources of variability in ASD on functional connectivity will directly inform interpretation of existing findings and guide ASD neurobiological models.
Objectives: Our goal was to quantify functional connectivity characteristics in ASD associated with medication use and psychiatric comorbidities in the context of serotonergic systems.

Methods: Four primary samples were identified from the Autism Brain Imaging and Data Exchange. ASD+SSRI (N=19) were taking an SSRI and no other psychoactive medications, and had no comorbid disorders; ASD-Unmedicated (N=19), an age, sex, IQ, and severity matched ASD comparison group with no medications or comorbidities; ASD+Anxiety (N=19) had a comorbid anxiety disorder and no medications; ASD-NoComorbid (N=19), an age, sex, IQ, and severity matched ASD comparison group with no medications or comorbidities. The four ASD groups will also be compared to typically developing age, sex, and IQ matched controls. Resting state fMRI data was analyzed using the Configurable Pipeline for the Analysis of Connectomes. Whole brain cross-correlation was performed using 116 cortical, subcortical, and cerebellar regions of interest from the Eickhoff-Zilles anatomical template.

Results: SSRI use was associated with reduced cerebellar-cortical and intra-frontal connectivity. In ASD patients taking an SSRI relative to unmedicated ASD Controls, cerebellar-default mode network (DMN) connectivity was increased (cerebellum and posterior cingulate, precuneus), and fronto-cerebellar connectivity was decreased (cerebellum and inferior frontal gyrus, rectal gyrus). In addition, SSRI use was associated with increased connectivity between right ventromedial prefrontal cortex and both left inferior frontal gyrus and right rectal gyrus.

Conclusions: Results indicate pervasive changes in functional connectivity associated with SSRI use and with comorbid anxiety in ASD. Altered cerebellar function has been implicated in ASD, and our findings suggest that SSRIs may mitigate cerebellar-DMN disconnections, an important finding because the DMN may be related to theory of mind and social impairments. We have also shown that comorbid ASD+Anxiety was associated with altered temporal pole connectivity. Anxiety comorbid with ASD includes more atypical symptoms than anxiety without ASD, and the marked changes in social-emotional and fear processing network connectivity provides important markers of ASD+Anxiety that may provide insight into unique neural mechanisms associated with anxiety in ASD.

257 **213.257** The Relationship between Autistic Traits, Eating Disordered Behaviours and Anxiety in the General Population

ABSTRACT WITHDRAWN

Background:

The high co-occurrence of autism and anorexia nervosa is well established (e.g. Huke et al., 2013), with higher levels of autistic traits commonly found in anorexic populations (Westwood et al., 2016). Further, general population studies show significant positive correlations between autistic traits and eating disorder traits relating to both anorexia nervosa and bulimia nervosa (e.g. Coombs et al., 2011).

However, studies investigating traits have predominantly relied on the Autism Spectrum Quotient (AQ; Baron-Cohen et al., 2001), which has not enabled specific examination of the impact of restricted and repetitive behaviours (RRBs) on eating disordered traits. In addition, anxiety is highly co-occurring with both autism and eating disorders (Kim et al., 2000; Swinbourne & Touyz, 2007) but little is known about how anxiety may influence the shared presentation of both autistic and eating disorder traits. Further, whether cognitive anxiety (i.e. related to thoughts such as worry and indecisiveness) or somatic anxiety (i.e. related to physical symptoms such as dizziness and shaking) is more relevant also remains unexplored.

Objectives:

1. To explore the specific associations between social communication difficulties and RRBs and eating disorder traits in the general population.
2. To additionally examine the effect of cognitive and somatic anxiety on these associations.

Methods:

Three-hundred and forty five adults (87% female; mean age 29.7 years, SD = 13.3) completed four online questionnaires: the AQ, the Adult Repetitive Behaviour Questionnaire-2 (RBQ-2A; Barrett et al., 2015; 2018), the Eating Attitudes Test-26 (EAT-26; Garner et al., 1982), and the State-Trait Inventory for Cognitive and Somatic Anxiety (STICSA; Grös et al., 2007). Mediation analyses were used to explore the mediating effects of cognitive and somatic anxiety on the relationship between autistic traits (social and communication difficulties, repetitive sensory motor behaviours (RSMB) and insistence on sameness (IS)) and three types of eating disordered behaviour (dieting, bulimia and food preoccupation, and oral control).

Results:

Preliminary analyses show that social and communication difficulties, RSMBs and IS all indirectly influenced dieting behaviour through their effect on cognitive anxiety. Similarly, social and communication difficulties, RSMBs and IS all indirectly influenced bulimia and food preoccupation behaviours through their effect of cognitive anxiety. A direct effect of social communication difficulties on bulimia and food preoccupation was also identified. There were no indirect pathways between autistic behaviours and oral control, but there was a direct pathway between IS and oral control.

Conclusions:

Using a general population sample, we found: 1) Social communication and RRBs independently contribute to the presence of eating disorder behaviours; 2) Anxiety generally has an important role in relationship between autistic and eating disorder behaviours. The data suggest the importance of considering the full spectrum autistic traits in those with high levels of eating disorder behaviour. Further, anxiety may be important clinical consideration for treatment approaches.

258 **213.258** The Role of Child and ASD Characteristics in Caregiver-Reported Anxiety: Correlates and Cluster Analyses from a Large Pooled International Database of Autistic Young People

Y. T. Lee[1], M. Uljarevic[2], J. W. Lerh[1], M. J. Hollocks[3], J. Rodgers[4], H. McConachie[5], A. Ozsivadjian[6], M. South[7], A. V. Van Hecke[8], A. Y. Hardan[9], R. Libove[9], E. Simonoff[10], S. R. Leekam[11] and ***I. Magiati***[1]*, (1)Psychology, National University of Singapore, Singapore, Singapore, (2)Stanford Autism Center, Department of Psychiatry and Behavioral Sciences, Stanford University, CA, (3)King's College London, Cambridge, UNITED KINGDOM, (4)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (5)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (6)St. Thomas Hospital, Evelina London Children's Hospital, london, UNITED KINGDOM, (7)Psychology & Neuroscience, Brigham Young University, Provo, UT, (8)Psychology, Marquette University, Milwaukee, WI, (9)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (10)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (11)School of*

Psychology, Cardiff University, Cardiff, NSW, United Kingdom

Background: Anxiety is one of the most common co-occurring conditions in ASD. However, studies that have investigated associations between child characteristics, ASD symptoms and anxiety are mostly of small sample sizes, tend to report inconsistent findings and have mostly explored overall (total) autism symptom severity scores. More in depth analyses of group clusters based on anxiety and ASD symptomatology profiles would enable greater understanding of the relationship between specific ASD characteristics and anxiety.
Objectives: This study pooled together data from 13 existing studies to examine the relationships between child characteristics (age, gender, cognitive/ adaptive functioning and ASD traits) and anxiety in a large sample. We also aimed to combine a variable-centered and person-centered approach in order to provide better understanding of the relationship between individual differences across anxiety subtypes with age, gender and core ASD traits.

Methods: A large international sample of 870 children and adolescents with ASD (763 males, 107 females, mean age 11.6 years, SD=2.77) was pooled together from 13 studies in the UK, Singapore and the US, all of which used the Spence Children's Anxiety Scale- Parent Version (SCAS-P) total and subscale scores. Several other different measures of functioning and ASD characteristics were employed by the different studies (i.e. WISC, WAIS, SCQ, SRS, etc.) and harmonized scores were created for these. Regression and moderation analyses using child characteristics and ASD traits as predictors were conducted for SCAS-P total and subscale anxiety scores. Latent profile analysis (LPA) with item level SCAS-P data will be used to identify profiles (groups) of individuals with distinct constellation of ASD symptoms. Models with 1-8 profiles will be estimated and the decision on the optimal number of profiles will be guided by the combination of information criteria, likelihood-based statistics and entropy. Derived anxiety based profiles will be further defined by exploring their association with core ASD traits, age and gender.

Results: Age was positively associated with social and generalized anxiety. No consistent gender differences were found. ASD symptoms, especially Repetitive and Restricted Behaviors and Interests (RRBIs), were positively associated with anxiety. At the item level, autistic symptoms relating to adherence to routine, intense special interests, sensory hypersensitivity and being aloof/ not showing feelings, together with participants' chronological age, were the most consistent predictors of SCAS-P anxiety symptoms. Tentative support that some moderation effects exist was also found, but effects were small. Cluster analyses are currently being carried out and these will also be reported.

Conclusions: The findings of this study strengthen existing literature examining the specific relationships between ASD symptomatology and anxiety in young autistic people. Implications of identifying distinct profiles/ groups and how this could enable more individualised targets for anxiety interventions are also discussed.

259 **213.259** The Structure of Co-Occurring Depression in Youth with ASD Living in Residential Care

B. Marro[1]*, T. Rosen*[1]*, L. Bungert*[1]*, R. Girard*[2] *and M. D. Lerner*[3]*, (1)Stony Brook University, Stony Brook, NY, (2)Developmental Disabilities Institute, Smithtown, NY, (3)Psychology, Stony Brook University, Stony Brook, NY*

Background:
Children with Autism Spectrum Disorders (ASD) more often exhibit co-occurring psychiatric conditions than not (Rosen et al., 2018). Frequently, ASD youth experience depression symptoms (Ghaziuddin et al., 2002). Some individuals with ASD express profound symptom presentation, requiring comprehensive care within inpatient or residential settings (Croen et al., 2006; Siegel at al., 2015). Individuals with ASD in these settings are underrepresented in the overall ASD literature, as well as the comorbidity literature more specifically (Lerner et al., 2018). There is evidence, though, that youth in in-patient settings display significant and observable challenges such as self-injury and suicidality (Siegel, 2018; Cassidy et al., 2014); this may indicate that inpatient youth experience significant difficulties related to depression, even though these observable challenges are not necessarily conceptualized as such. Youth in psychiatric inpatient settings experience co-occurring psychiatric symptoms differently than those in the community (Mandell, 2008; Siegel et al., 2018), suggesting that symptom presentation in ASD may be dependent on treatment setting. Though research regarding inpatient populations is emerging, symptom presentation in a residential setting remains to be explored. Though there may be similarities between the settings, residential settings are typically long term, while in-patient settings are frequently acute. Therefore, symptom presentation in residential settings is likely to vary from in-patient or community settings.

Objectives: To determine how ASD youth in a residential setting experience depression symptomology.

Methods:

Data were collected via the Child and Adolescent Symptom Inventory (CASI-5; Gadow & Sprafkin, 2013) from teachers of 146 youth (M_{age} = 15.27, SD_{age} = 3.12; 119 male) in state-funded residential facilities across New York state. Participants had severe intellectual (IQ ≤ 70) and adaptive ($M_{Vineland}$ = 43.25, $SD_{Vineland}$ = 14.11) difficulties. An exploratory factor analysis (EFA) of the CASI-5 depression scale using Maximum Likelihood estimation and Geomin rotation was conducted.

Results:

The EFA supported a 5-factor model of depression symptoms, which accounted for 72.2% of item variance (Table 1). The factors were, anhedonia/difficulty concentrating, /verbally mediated symptoms, low energy level, suicidality and functional changes (Table 2).

Conclusions: Whereas outpatient and non-treatment seeking youth have depression symptoms that form only one or two factors (Bitsika et al.,2016; Lecavalier, Gadow, Devincent, Houts, & Edwards, 2011; Uljarević et al., 2017), these residential samples evince depression symptoms that consist of five factors. These results indicate that ASD youth in residential settings may experience multi-faceted symptomology compared to inpatient and outpatient ASD youth. Obtained factors, such as functional changes related to depression (i.e., change in activity level, sleep, appetite etc.), and anhedonia and fatigue (acts unhappy or sad, shows little enjoyment in pleasurable activities), may be less verbally mediated, and therefore more easily observed and coherently identified in patients with lower verbal abilities (Righi et al., 2017, Siegel et al., 2018), such as those receiving residential care. Understanding this population's symptom presentation will inform and guide treatment practices for this understudied population, as it may be useful for treatments to be targeted to these multi-faceted and specific symptom domains, rather than to discrete diagnostic categories.

260 **213.260** Trends in Psychotropic Medication Use for Canadian Children and Youth with ASD from 2012 to 2016: A Pharmacoepidemiologic Study

C. A. McMorris[1]*, S. B. Patten*[2]*, D. Stewart*[3]*, A. Tehrani*[4] *and T. M. Pringsheim*[2]*, (1)Werklund School of Education, University of Calgary, Calgary, AB,*

Canada, (2)Department of Psychiatry, University of Calgary, Calgary, AB, Canada, (3)IQVIA, Kanata, ON, Canada, (4)IQVIA, Kirkland, QC, Canada

Background: The majority of children and youth with autism spectrum disorder (ASD) experience a co-occurring mental health issue, such as anxiety or depression. Pharmacological interventions are commonly used to manage and treat these psychiatric issues, as well as aggression or self-injurious behaviours that are common in individuals with ASD. While psychotropic medications are used quite extensively, these drugs often have variable treatment response, and the US Food and Drug Administration (FDA) has only approved two drugs, risperidone and aripiprazole, for use in individuals with ASD. Although it is well established that children and youth with ASD are a highly medicated group in various countries, no study has examined recommendations for psychotropic medication in Canadian children and youth with ASD exclusively, nor described how these patterns may be changing over time.

Objectives: The objective of this study is to describe the frequency and psychotropic prescription trends for behavioural challenges and mental health issues in children and youth with ASD in Canada from 2012 to 2016.

Methods: The present study used data from IQVIA's Canadian Disease and Therapeutic Index (CDTI), which is survey-based dataset that collects treatment data from a representative sample of office-based physicians related to drug recommendation, indication and patient demographics. Quarterly, during a 48-hour period, participating Canadian physicians complete an anonymized record of all patient visits including patient age, gender, drug recommendation (prescribed medication), and reason for recommendation. Statistical weighting adjustments are made to the sample-based estimates to extrapolate drug recommendations to national totals.

Results: The analysis will focus on drug recommendations for antidepressants and ADHD medications for children and adolescent (under 18 years of age) with ASD from 2012 to 2016, and for antipsychotics from 2010 to 2016. Data has been collected and the analysis will be completed in Winter 2019. Preliminary data analysis showed that within the three medication classes, antipsychotics were the most commonly prescribed psychotropic medications in children with ASD. Risperidone was the most commonly recommended medication, followed by aripiprazole. Between 2010 and 2016, drug recommendations for antipsychotics grew steadily, from 35,010 recommendations in 2010, to 90,288 recommendations in 2016. The use of antidepressant medications remained fairly steady between 2012 and 2016, with a total of 26,053 drug recommendations in 2016; sertraline was the most commonly recommended antidepressant. ADHD medication use also remained steady between 2012 and 2016, with a total of 52,929 drug recommendations in 2016. Clonidine and methylphenidate were the most commonly recommended medications in this class.

Conclusions: Psychotropic medication is used extensively with children and youth with ASD. This is the first study to show an increase in antipsychotic use in Canadian children and youth with ASD. Findings will help to inform prescription guidelines for psychotropic medications, and highlight the importance of medication monitoring.

261 **213.261** What Do Autistic People Who Experience Anxiety Tell Us about Existing Interventions and Services for the Treatment of Anxiety?

S. Brice[1], *J. Rodgers*[2], *M. Freeston*[3], *B. Ingham*[4], *A. LeCouteur*[5], *C. Wilson*[6] *and J. R. Parr*[2], *(1)Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (3)Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (5)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (6)Autism advocate, Sunderland, United Kingdom*

Background: Anxiety is a common mental health condition experienced by autistic people, with the potential to negatively impact on many aspects of daily life. The development of effective treatments for anxiety is a key priority for autistic people. Clinical guidance and policy documents recommend that interventions should be adapted to meet the needs of the autistic person. To inform the development of effective treatments it is important to learn about the lived experiences of autistic adults who experience anxiety including those who have accessed existing interventions and services.

Objectives: To conduct a UK survey to learn about autistic adults' experiences of anxiety and any treatments received; and to explore autistic adults' perspectives about what types of adaptations to mental health interventions and services would meet their needs.

Methods: Autistic adults aged 18 and over were recruited via the Adult Autism Spectrum Cohort-UK (Newcastle University). 824/1587 cohort participants reported an anxiety diagnosis (51.9%) and a further 23.4% reported a suspected but undiagnosed anxiety disorder. Of the 998 with a pre-existing diagnosis (or suspected diagnosis) of anxiety, 449 (45%) completed a survey about their experiences of anxiety and treatments they have accessed. Their mean score on the Social Responsiveness Scale (measuring autism severity) was 111.5, exceeding the suggested cut-off for autism. Analyses were principally descriptive and correlational.

Results: 60.3% had completed psychological therapy for anxiety; 72.1% had been prescribed medication. Of those who had completed psychological therapy for anxiety just 5.8% reported they had made a full recovery and 53.9% a partial recovery. The treatment made 'no difference' for 28.4% of respondents and 11.9% 'felt worse' (supporting qualitative data available). These outcomes are poorer than observed in the general population. Autistic people rated adjustments to treatments and services as being very important but rarely available. For example, 'having a therapist who understands autism' was rated as an important key adjustment by 98.4% of the sample (86.8% very important, 11.6% somewhat important) but 31.6% of participants reported that this was 'never available' and a further 39.7% reported it was 'rarely available'. Similar patterns of high importance and low availability were observed across a number of key adjustments such as altering the sensory environment of therapy locations and adaptations to the therapeutic intervention itself. Overall, the more important that an adjustment was rated, the less likely it was to be widely available ($r = -.20$, $p < .01$) and a significant correlation was observed between availability of adjustments and therapeutic outcomes ($r = .34$, $p < .01$).

Conclusions: This study demonstrates some of the shortcomings of therapeutic interventions for anxiety experienced by autistic people. Understanding the range and types of adjustments valued by autistic adults can inform hypothesis driven research and lead to more clinical and cost effective treatments for anxiety experienced by autistic people. Building on the findings of this survey, our research team is currently undertaking a pilot feasibility trial for a personalised, modular psychological intervention for anxiety experienced by autistic people.

262 **213.262** Waveform Morphology in EEG Parses Heterogeneity in Autism and Schizophrenia

A. Naples[1], *J. Foss-Feig*[2], *K. S. Ellison*[1], *B. Lewis*[1], *V. Srihari*[3], *A. Anticevic*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Autism (ASD) and Schizophrenia (SCZ) share core and comorbid symptoms such as sensory sensitivities, reward processing impairments, and social difficulties. Electrophysiological (EEG) investigations of these symptoms have primarily focused on oscillatory activity; however, recent research suggests that important aspects of EEG are not strictly rhythmic. Instead, they include non-stationary bursts and waveform shape, biophysically meaningful features used often in clinical evaluation of the EEG. Nevertheless, these features are infrequently used to assess brain activity between and within diagnostic groups.
Objectives: To use innovative metrics of EEG shape to quantify resting brain activity and its association with diagnosis and clinical characteristics in ASD and SCZ. Specifically: (1) the slope of the resting power spectrum (PSD); (2) the presence of oscillatory "bursts;" (3) Nonsinusoidal features of EEG shape.

Methods: Resting EEG was collected in 105 individuals: 33 ASD, 28 SCZ, and 44 typically developing (TD) controls. EEG was recorded for 4 minutes with eyes open and 2 minutes with eyes closed. Slope of the PSD was calculated from 1-30Hz. Waveform shape was quantified as the symmetry between the peak and trough, or rise and decay, of a cycle, aspects of the EEG that reflect underlying physiology but are not captured in frequency analyses (e.g., the symmetry between the rise and decay influence the EEG's tendency to exhibit a "sawtooth" shape). Bursts were defined as at least three cycles that exhibited the same symmetry characteristics. These EEG metrics were calculated cycle-by-cycle across frequency bands, and averaged, per-person. A regression tested EEG association with diagnosis and correlations assessed EEG association with symptomology.

Results: Compared to TD, SCZ had fewer bursts in alpha across the scalp, in beta across occipital regions, and in gamma frontally [parameters ranging b=-.14, p=.017 to b=-.20, p=.001]. Compared to ASD, SCZ exhibited fewer bursts in alpha [parameters ranging b=-.13, p=.03 to b=-.18, p=.006]. With respect to waveform shape, compared to TD, both SCZ and ASD exhibited increased peak-trough symmetry in frontal theta (ps<.005), indicating waveforms with sharper troughs. Individuals with SCZ exhibited faster oscillatory bursts (higher peak frequency) in the theta, alpha, and beta bands [parameters ranging b=2.9, p=.03 to b=10.1, p=.02]. Waveform shape correlated with symptomology, with faster rises in frontal theta (r=-.28, p=.004) and drops in occipital beta (r=.24, p=.015) predicting greater ADOS severity scores. With respect to PSD shape, SCZ differed from TD with more negative slope (b=-.07, p=.03) in the occipital regions, indicating more high-frequency power associated with increased excitatory activity.

Conclusions: The shape of EEG waveforms reflects underlying cortical activity. While assessment of EEG shape is common clinical practice, research has focused, primarily, on oscillatory approaches. We show, for the first time, that objective, non-oscillatory measures in clinical groups strongly associate with diagnosis and symptoms. This approach offers insight into low-level activity generated by cortical inhibition and excitation, supporting a better understanding of the biological substrates. Ongoing analyses incorporating sensory and ASD symptomology will further explicate these relationships and allow us to better differentiate subgroups of individuals exhibiting similar brain activity and symptom profiles.

Poster Session
214 - Molecular Genetics
5:30 PM - 7:00 PM - Room: 710

263 **214.263** A De Novo Truncating Mutation of the Gene Encoding Nucleolin in an ASD Individual Disrupts Its Nucleolar Localization

T. Sheikh[1] *and J. Vincent*[2]*, (1)Centre for Addiction & Mental Health (CAMH), Toronto, ON, Canada, (2)Centre for Addiction & Mental Health, Toronto, ON, Canada*

Background: Nucleolin (NCL / C23; OMIM: 164035) is a major nucleolar protein that plays a critical role in multiple processes including ribosome assembly and maturation, chromatin decondensation, and pre-rRNA transcription. Due to its diverse functions, nucleolin role has frequently been implicated in pathological processes, including cancer and viral infection.
Objectives: To study the functional effect of a *de novo* frameshifting indel mutation (Gly664Glufs*70), identified through whole exome sequencing in an autism spectrum disorder trio.

Methods: Nucleolar localization and real-time protein dynamics studies using constructs encoding either wild type human nucleolin or a mutant nucleolin with the same C-terminal sequence predicted for the autism proband into mammalian cells.

Results: Using co-localization with nucleophosmin (NPM; B23) protein, we have shown that the mutant nucleolin leads to mislocalization of the NCL protein from the nucleolus to the nucleoplasm. Moreover, a construct with a nonsense mutation at the same residue, p.Gly664*, shows a very similar effect on the location of the NCL protein, thus confirming the presence of the nucleolar location signal of NCL protein in this region. Real time fluorescent recovery experiments show significant changes in the kinetics and mobility of mutant NCL protein in the nucleoplasm of HEK293Tcells.

Conclusions: Several other studies report *de novo* mutations in NCL in ASD or neurodevelopmental disorders. The altered mislocalization and dynamics of mutant NCL (p.G664Glufs*70/ p.G664*) may have relevance to the etiopathlogy of NCL-related neurodevelopmental phenotypes.

264 **214.264** Air Pollution Exposure Alters Expression of Genes in Human Neurons Previously Implicated in ASD

K. C. Lewis*, S. M. Bilinovich and D. B. Campbell, Pediatrics and Human Development, College of Human Medicine, Michigan State University, Grand Rapids, MI*

Background: The link between air pollution and an increased risk of autism spectrum disorder (ASD) is well established. While some forms of ASD originate due to genetic mutations, environmental factors play a large role in epigenetic changes leading to altered brain development. There exists a need for better understanding of molecular changes and biological pathways impacted by model air pollutants.
Objectives: Expose cortical neural progenitor cells to diesel particulate matter (DPM; concentrations 10, 20, 50, 100 ug/mL) to understand the impact on molecular and biological pathways, and the expression of genes associated with ASD. RNA-seq differential gene expression (DE) contrasting each DPM exposure concentration versus control determined biological pathway enrichment using Gene Ontology.

Methods: ReNcell CX neural progenitor cells were exposed to DPM for 24 hours. Following exposure, four biological replicates of each DPM dose

were used to extract RNA for RNAseq.

Results: Comparison of DE genes (pval < 0.05) to the Simons Foundation Autism Research Initiative (SFARI) database showed the number of ASD-related genes increased as DPM dose increased. Dose 10 ug/mL and 20 ug/mL had 30 genes, 7 classified as syndromic. Dose 10 ug/mL had two genes associated with Rett Syndrome, *CDKL5* and *FOXG1*, as well as *FOXP1*. Dose 50 ug/mL had 34 genes and 8 syndromic genes, including *DEAF1*. Dose 100 ug/mL had 46 genes and 9 syndromic genes including *DMD*, *CHD2* and *CDKL5*. The majority of these genes were expressed higher in DPM-treated samples than control. In addition, pathway overrepresentation included chromatin remodeling, regulation of telomere maintenance, translation initiation factor activity, DNA replication regulation and endocytosis.

Conclusions: Neural progenitor cell exposure to DPM resulted in a dose dependent increase in differentially expressed genes associated with ASD. The rise in syndromic genes is particularly interesting and warrants further investigation. Furthermore, pathways associated with modifications to DNA were overrepresented due to DPM exposure showing this environmental factor does influence the biological pathways.

265 **214.265** Altered Gene Expression Levels in mTOR Signaling Pathway and Their Association with Cytokine Levels in Idiopathic ASD

B. Stamova[1], *J. Schauer*[2], *F. Sharp*[1] *and J. Van de Water*[2], *(1)Neurology, University of California at Davis, School of Medicine, Sacramento, CA, (2)MIND Institute, University of California, Davis, Davis, CA*

Background: In addition to mTOR/Akt/PI3K Signaling being implicated in single gene causes of ASD, we and others have reported aberrant gene expression levels of genes from the mTOR Signaling pathway in idiopathic ASD. mTOR Signaling is a principal pathway that regulates cellular metabolism, growth, survival, and autophagy. It plays important roles in both innate and adaptive immune responses, such as promoting differentiation, activation and function of B-cells and regulatory and effector T-cells, development and activation of NK cells, in monocyte and neutrophil function, and in regulating cytokine production in the immune system. Thus, we investigated the expression of several mTOR signaling genes we have previously shown to be differentially expressed in ASD vs. TD (typically developing controls) and correlated their expression levels to cytokine/chemokine levels in the same subjects.

Objectives: 1) To validate in a new cohort our previous findings of differential expression of mTOR signaling genes (AKT3, EIF4A2, FNBP1, NAPEPLD, PIK3C3, PPP2R2A, PPP2R1B); 2) to investigate the correlation between the expression of these mTOR signaling genes in whole blood, and the levels of cytokines/ chemokines in PBMC (peripheral blood mononuclear cells), as well as following stimulation by PHA or LPS.

Methods: qRT-PCR was performed on the selected mTOR Signaling genes on RNA isolated from whole blood from 23 male and 7 female children diagnosed with ASD (average age 3.8 yrs), and on age-matched 38 male and 7 female TD children (average age 3.6 yrs); age was not significantly different between ASD and TD. Cytokine/chemokine production levels were measured on the same subjects from isolated PBMC (peripheral blood mononuclear cells) stimulated with PHA, LPS, or media alone. Mixed Regression analysis using PCR batch as a random factor, and Dx as a fixed factor, was used to identify differentially expressed genes between ASD and TD in a sex-specific manner (FDR $p<0.05$). Pairwise Pearson correlation coefficients were calculated for all mTOR-gene – Cytokine/chemokine comparisons ($p<0.05$ considered significant) in ASD male, ASD female, TD male, and TD female separately.

Results: Our previous array study identified differential expression in the tested 7 genes in idiopathic ASD male compared to TD male. In the current study, in a separate cohort, we validated this finding in 5 (AKT3, EIF4A2, FNBP1, NAPEPLD, PIK3C3) of the 7 genes, which showed differential expression in ASD males vs. TD males (FDR $p<0.05$, up-regulated in ASD vs TD) (Fig. 1a). No gene was differentially expressed in ASD females vs. TD female (Fig. 1b). Both male and female ASD showed altered correlation association between mTOR-genes and many of the cytokines/chemokines tested in comparison to control subjects for both non-stimulated and stimulated conditions.

Conclusions: The aberrant expression of mTOR signaling genes may affect the immune system, as evidenced by changes in the correlation network between mTOR genes and cytokine/chemokine levels in ASD compared to TD. Due to the role of mTOR signaling as a central integrator of extracellular and intracellular growth signals, as well as cellular metabolism and immune system function, these genes and pathways may ultimately affect behavior.

266 **214.266** Analysis of Circular RNAs Identified from iPSC-Derived Cortical Neurons from Individuals with Idiopathic Autism

A. J. Griswold*, D. Van Booven, H. N. Cukier, D. Dykxhoorn and M. A. Pericak-Vance, John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL*

Background: Induced pluripotent stem cells (iPSCs) provide an attractive model of the cellular and molecular changes that underlie autism (AUT). Previous RNAseq analysis in our laboratory from cortical neurons derived from iPSC lines of individuals with idiopathic AUT and typically developing controls identified sets of differentially expressed genes enriched in pathways including neuronal differentiation, axon guidance, cell migration, and neural region patterning (De Rosa 2018). However, these protein coding RNAs represent only a fraction of the total transcripts identified and the non-coding repertoire, including circular RNAs (circRNAs), remains mostly unexplored. circRNAs are abundantly expressed, formed by alternative splicing of pre-mRNA, and have functions including post-transcriptional regulation, RNA binding protein sequestration, and transcriptional machinery scaffolding. These diverse functions suggest that differential expression of these molecules may have important developmental roles related to AUT.

Objectives: The goal of this study is to compare differentially regulated non-coding circRNAs in idiopathic AUT-specific iPSC-derived cortical neurons vs neurons derived from iPSCs from typically developing controls. Moreover, we aim to identify temporal regulation and differential expression of circRNAs by examining their profiles over a developmental time course in both AUT and control neurons.

Methods: iPSC lines were created from peripheral blood mononuclear cells (PBMCs) and developed from six individuals with autism and five typically developing controls. These iPSC lines were differentiated into cortical neurons and RNA was extracted at three time points post initiation of differentiation (day 35, 85, and 135). Total RNA was ribosomal RNA depleted and sequenced to at least 50 million paired end 100bp on the HiSeq2500. Following processing and alignment of reads to the hg19 reference genome with the TopHat2 aligner, three separate methods were used to detect circRNA in the samples: CIRI2, CIRCexplorer2, and circRNA_finder. Intronic and intergenic circRNA were discarded and exonic circRNAs with ≥ 3 junction spanning reads in ≥ 3 samples were considered expressed.

Results: In total, we identified ~11,000 expressed circRNA across all of the samples. Only 35% of circRNAs were identified by all three callers, but that number increased to over 70% when including only those with at least 15 junction reads. Individual sample counts rangd from 1200-8000 with

the counts highly correlated with number of total reads (Pearson correlation coefficient = 0.86). There was no difference in overall circRNA counts between AUT and controls, nor were there differences between samples or groups across time points. Looking at specific circRNAs, we did identify the well characterized CDR1-AS, a circular RNA highly expressed in the central nervous system that functions as a sponge for miR-7 (Memczak, et. al., 2013, Nature). Moreover, we identified 445 circRNAs from 103 genes considered either syndromic or a strong candidate according to the SFARI Human Gene database. We are currently investigating the differential expression of these candidates.

Conclusions: The results of this study show that there is a diversity of circRNAs are expressed in cortical neurons derived from AUT-specific and control iPSC lines. Continued exploration of these and other noncoding transcripts will identify novel gene regulatory roles in autism.

267 **214.267** Analysis of Phenotypes Associated with De Novo Pathogenic Loss-of-Function (pLOF) Variants in the Developmental Brain Disorder Gene Database: Are There Autism-Specific Genes?

***S. M. Myers**, H. Shimelis, K. E. Wain, T. Challman, B. Finucane, C. L. Martin and D. H. Ledbetter, Geisinger Autism & Developmental Medicine Institute, Lewisburg, PA*

Background: Pathogenic variants involving the same genes are identified in a variety of different clinical disorders, including autism spectrum disorder (ASD), intellectual disability (ID), epilepsy, schizophrenia, and other neurodevelopmental and neuropsychiatric conditions. It has been asserted that some genes are more ASD-specific (or ASD-predominant) and others are more specific for ID and other severe neurodevelopmental disorders (NDD) with or without ASD, based on whether the individuals were ascertained from ASD studies or ID/NDD studies (Satterstrom et al., bioRxiv 2018; doi.org/10.1101/484113).
Objectives: We examined whether there is evidence in our Developmental Brain Disorder Gene Database (DBD Gene Database) that pathogenic *de novo* LOF mutations in DBD-associated genes preferentially or exclusively cause ASD but not ID.

Methods: We used our DBD Gene Database (https://geisingeradmi.org/care-innovation/studies/dbd-genes/; Gonzalez-Mantilla et al., 2016), which integrates genomic data, including structural and sequence pLOF variants from exome and genome sequencing, copy number arrays, and targeted genomic studies published through March, 2018, with phenotype data on 6 clinically-defined disorders (including ASD and ID) to examine the phenotypes associated with pathogenic *de novo* LOF variants in DBD-associated genes. Analysis was limited to genes with ≥10 total probands with *de novo* variants in the database. The subset of these genes for which there were ≥10 ASD cases in the database, excluding individuals without ASD, was also evaluated.

Results: Among the 49 genes for which there were at least 10 total probands with *de novo* variants in the DBD Gene Database, none were associated exclusively with ASD (Figure 1). For 3 genes, *CHD8*, *SHANK3*, and *SCN2A*, there were more individuals with ASD-only than with ID-only, but many had both diagnoses, and for each gene there were more individuals with ID than without ID (ID rates 59%, 57%, and 58%, respectively). We separately examined the subset of these genes (*ADNP*, *CHD8*, *NRXN1*, *POGZ*, *SCN1A*, *SCN2A*, and *SYNGAP1*) for which there were ≥10 ASD cases, excluding individuals without ASD, and there was no evidence of enrichment for the ASD-only phenotype (Figure 2). Among these individuals with ASD, the rates of concurrent ID were as follows: *ADNP* 69%, *CHD8* 56%, *NRXN1* 64%, *POGZ* 73%, *SCN1A* 56%, *SCN2A* 48%, and *SYNGAP1* 64%.

Conclusions: We found no evidence of ASD specificity for genes with ≥10 total probands with *de novo* variants in the DBD Gene Database, even when limiting the analysis to individuals with ASD. Mutations that cause ASD also cause ID in most individuals, and for some genes in this database the phenotype is exclusively or predominantly ID (without ASD). However, answering the question of whether rare pathogenic variants in certain genes confer risk that is ASD-specific requires adequate phenotyping of all affected individuals studied, providing equal opportunity for diagnosis of each condition. Among individuals whose developmental brain dysfunction is attributable to a rare variant of large effect size, factors such as background polygenic risk (conferred by many common variants of small effect size) and developmental stochastic variation may be more important determinants of the specific neurodevelopmental phenotype(s) expressed than the gene(s) involved in the primary etiology.

268 **214.268** Cadherins Matters to Autism Spectrum Disorders: Which Ones?

*M. R. Passos-Bueno[1], **C. I. Samogy Costa**[2], E. M. Montenegro[3], E. S. Moreira[4], C. Rosenberg[2], S. S. Costa[3], A. Krepischi[2] and N. Lourenço[2], (1)Centro de Pesquisas Sobre o Genoma Humano e Células-Tronco, Instituto de Biociências, Universidade de São Paulo, Sao Paulo, Brazil, (2)Universidade de São Paulo, São Paulo, Brazil, (3)University of Sao Paulo, Sao Paulo, Brazil, (4)Evidencias-Kantar Health, Sao Paulo, Brazil*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition with a known strong genetic component. Genomic analysis have shown that de novo and rare loss-of function mutations are important for the etiology of ASD and oligogenic/multifactorial models is expected to be associated with most of the cases. It has also been shown that disruption of genes functionally important for neuronal cytoskeletal and synaptogenesis contributes to the phenotype, but one currently challenge is to identify which are the variants with clinical effect.
Objectives: Identify novel ASD loci or to confirm previous CNVs hits.

Methods: CMA analysis was performed in 121 ASD cases (105 cases using an aCGH 180K platform that was previously customized and validated in our lab, and 16 cases using different CMA platforms). All CNVs detected were characterized by size, type, population frequency and gene content. Common polymorphisms (CNVs occurring in more than 1% of the population) or without genes were excluded from further analysis. International Standard Cytogenomic Array (ISCA) and the American College of Medical Genetic (ACMG) standards were taken into account to classify the remaining CNVs as pathogenic, benign, or variant of uncertain clinical significance (VOUS). Finally, our findings were validated in a cohort of 1,029 Brazilian patients with neurodevelopment disorders

Results: CNV analysis in a Brazilian cohort of 121 patients by chromosomal microarray analysis (CMA) revealed 31 potentially pathogenic CNVs. Of these, 26 contained 27 ASD candidate genes and 15 CNVs contained genes not yet described in ASD patients. Two out of these 31 CNVs embraces genes of the cadherin family (*CDH11, CDH8*and *CDH13*). Screening of a Brazilian cohort composed by 1,029 patients with neurodevelopmental disorders revealed one CNV embracing *CDH13*, TRIM16 and *PTPNR2*genes, thus reinforcing the association of *CDH13*with neurodevelopmental disruption. *CDH11*and *CDH8*have been pointed out as possible ASD candidate genes and are listed in SFARI database, but with minimum evidence (score 4; http://sfari.org), however, *CDH13*, which plays an important role in axonal pathfinding and synaptogenesis is not yet included in this database neither suggested as a good ASD candidate.

Conclusions: Our findings suggest that disruption of these cadherin genes may represent a predisposing hit in ASD and CDH13 should be included as a novel ASD candidate gene.

The Project was supported by Fundação de Amparo à Pesquisa do Estado de São Paulo - FAPESP/ CEPID, Conselho Nacional de Desenvolvimento Cientifico e Tecnológico - CNPq and Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - CAPES

269 **214.269** Identifying NRXN1 Function during Neural Differentiation of iPSC

L. Dutan Polit[1], *R. Nagy*[1], *D. Adhya*[2], *N. J. Gatford*[1], *A. T. Massrali*[3], *A. Paul*[4], *J. Price*[1], *M. R. Kotter*[5], *S. Baron-Cohen*[6] *and D. P. Srivastava*[1], *(1)Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology, and Neuroscience, King's College London, London, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)Department of Psychiatry, Autism Research Centre, Cambridge, United Kingdom, (5)Department of Clinical Neurosciences, Wellcome Trust-MRC Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom, (6)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Neurexins are a family of presynaptic adhesion molecules that interact with post-synaptic proteins to regulate synapsis formation and maintenance. NRXN1 mutations have been strongly associated with a range of neurodevelopmental conditions including autism, attention deficit and schizophrenia (Kasem et al., 2017; Shehhi et al., 2018). Specific mutations such us NRXN1 determine autism likelihood but any particular phenotype is an emergent property of regulatory interactions that combines genetic and epigenetic regulation in a functional genome (Karlebach & Shamir, 2008; Huang et al. 2009; Gomez et al. 2011; Vashishtha et al., 2015). For instance, it has been demonstrated that inhibition of NRXN1 in neuronal progenitors derived from iPSC leads changes in the expression of genes enriched that regulate cell biological functions such as cell adhesion and neuronal differentiation, suggesting a potential role for NRXN1 during early neural development (Zeng et al., 2013). Hence, to unravel the molecular mechanism that lead to the autism phenotype in individuals with NRXN1 mutations, it is necessary to identify NRXN1 protein interactions and the cell biological processes regulated by these gene modules during neuronal development.
Objectives:

- To use induced pluripotent stem cells (iPSC) as an *in vitro* system to recapitulate the regulatory interactions underlying the transition from pluripotency to neural competence in humans.
- To capture the early molecular differences of neurotypical and NRXN1 mutated iPSC lines as they undergo during neuronal differentiation.

Methods: We used iPSC lines derived from 3 neurotypical and 3 autistic individuals with NRXN1 deletions and induced neural differentiation by dual SMAD inhibition (2i). RNA was extracted at 6 time points during the initial 12 days of neural induction and cDNA was synthesized to obtain transcriptome data. The expression patterns of NRXN1a, NRXN1b and genes that have been associated with NRXN1 was analysed in control and NRXN1 mutated lines trough real time PCR

Results: NRXN1 is expressed during early neural induction, suggesting a potential role during neural development. We identify a number of genes that are expressed during this stage that might interact with NRXN1 including neuroligins and other adhesion molecules. We detect systematic changes in the expression levels of genes that have been related with NRXN1 in the mutated cell lines compared with control lines undergoing neuronal differentiation. We identify potential cell biological functions regulated by these sets of genes including cell adhesion and neural rosettes formation.

Conclusions: iPSCs provide a novel approach to study the impact of NRXN1 mutations during neural differentiation in humans, highlighting the utility of iPSC model in understanding the functional role of specific mutations that are associated with autism risk. We show that NRXN1 gene mutations can impact biological networks that are important for neural differentiation.

270 **214.270** Modeling the Effect of Diesel Particulate Matter on Human Induced Pluripotent Stem Cell Derived Cerebral Organoids and Mixed Neural Cultures

S. M. Bilinovich, *K. L. Uhl, K. C. Lewis, D. Vogt, J. W. Prokop and D. B. Campbell, Pediatrics and Human Development, College of Human Medicine, Michigan State University, Grand Rapids, MI*

Background: Diesel particulate matter (DPM) exposure during fetal development has been implicated in the increased risk of autism spectrum disorders (ASD).[1] However, current methods dissecting the molecular effects of DPM on neural development are often performed in cell lines or non-human models instead of the multicellular environment of the developing human brain. To overcome this challenge, we used a combination of cerebral organoids and adherent differentiated neurons derived from human induced pluripotent stem cells (hiPSC) to study the effect of DPM on human neuronal development. Our data suggest a potential molecular model of DPM action in human brain development.
Objectives: To study the structural and molecular changes to neurons developing within cerebral organoids and mixed neural cultures to better model the impact of DPM on human brain development.

Methods: We used commercially derived hiPSC lines differentiated into cerebral organoids and mixed neural cultures. The cerebral organoids were treated with DPM for a length of ten days after reaching maturation and analysis of gene expression was determined using RNA-seq and immunocytochemistry. The differentiated mixed neural cultures were treated with DPM for 24 hours and analyzed by RNA-seq and immunocytochemistry.

Results: Genes shown to be downregulated (137 genes) in cerebral organoids treated with DPM based on gene ontology analysis (pval <0.05) showed an enrichment in biological processes including regulation of synaptic activity, regulation of Schwann cell differentiation, and axonal transport. Upregulated genes (453 genes) with a biological process enrichment based on gene ontology analysis (pval <0.05) include SNARE complex disassembly and TORC2 signaling. Analysis of cerebral organoids identified several genes differentially expressed of interest in ASD such as *SGCE* (a MECP2 binding target). Other differentially expressed genes include *TBL1XR1* and *KANSL1* that are implicated in intellectual disability disorders. As additional data is collected on the mixed neural cultures we expect to continue resolving mechanisms for DPM.

Conclusions: Diesel particulate matter is a known environmental factor that increases the risk of ASD. The use of hiPSCs derived cerebral organoids and mixed neural cultures show that they can be used to study the environmental effects of DPM on autism, and that organoids can be used as a 3-D model of exposure risk in neurodevelopmental disorders.

271 **214.271** Protecting DNA Is a Family Affair: Telomere Length and Cognition in Affected Individuals, Unaffected Siblings, and Parents

***C. R. Lewis**[1], F. Taguinod[1], J. E. Cohen[1], N. Walker[1], K. Agrawal[2], W. Jepsen[1], M. Huentelman[1], C. J. Smith[3], S. Ringenbach[2] and B. B. Braden[2], (1)Translational Genomics Research Institute, Phoenix, AZ, (2)College of Health Solutions, Arizona State University, Tempe, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Although not a diagnostic criterion, individuals with ASD commonly experience cognitive difficulties. One possible mechanism is shortened telomeres. Telomeres are repetitive non-coding DNA nucleotides that protect genes by capping chromosome ends and progressively shorten with age. Recently, two reports associated shortened telomere length (TL) with ASD or familial relation. Further, shortened telomeres have been associated with age-related cognitive decline. While previous studies found no relationship between TL and ASD core symptoms, the relationship between TL and cognitive function or sensory symptoms in individuals with ASD and family members is unknown.
Objectives: We aimed to replicate the finding of shortened TL in children with ASD compared to neurotypical (NT) controls, and add new findings concerning TL in unaffected siblings. We investigated relationships between TL, cognition, and ASD-related behaviors in affected individuals, unaffected siblings, and parents.

Methods: Our participants (n=380) included 69 male NT controls (7.1±2.3 years), 108 individuals with ASD (11 female; 8.3±8.4 years), 136 unaffected siblings (66 female; 10.3±7.3 years), and 67 parents (43 female; 38.7±8.4 years). TL of DNA derived from blood leukocytes was determined using an established quantitative polymerase chain reaction method. Cognitive function was measured via Stanford-Binet Intelligence Scale-5, core symptoms via Autism Diagnostic Observation Schedule-2, sensory symptoms via Sensory Profile, and ASD-related behaviors in parents via Broader Autism Phenotype Questionnaire (BAPq).

Results: Among male NT, ASD, and unaffected siblings, there was a significant ANCOVA [$F(2, 232)=6.12$, $p=0.003$], with NT males having longer TL than males with ASD ($p=0.001$) and unaffected siblings ($p=0.05$), controlling for age (Fig. 1a). In a mixed-model, males with ASD were not different from male unaffected siblings [$F(1, 160)=2.48$, $p=0.12$; Fig. 1b], controlling for age. However, when including both sexes (with sex covariate), unaffected sibling's TL were longer than individuals with ASD [$F(1, 232)=5.39$, $p=0.02$], driven by females [$F(1, 70)=4.77$, $p=0.03$]. In individuals with ASD, TL was not related to core symptoms, but negatively related to sensory symptoms [vestibular: $r(86)=-0.27$; $p=0.001$ (Fig. 2a); visual: $r(84)=-0.25$; $p=0.02$; touch: $r(80)=-0.23$; $p=0.03$]. TL was positively related to cognition in parents only [knowledge: $r(44)=0.40$; $p=0.006$ (Fig. 2b); working memory: $r(44)=0.29$; $p=0.05$]. Parent's TL was also positively related to the BAPq aloof domain [$r(41)=0.43$ $p=0.004$].

Conclusions: We replicated shortened TL in individuals with ASD compared to NT controls. This is the first study to demonstrate unaffected siblings' TL is also reduced, but to a lesser degree than their affected siblings, which may be driven by females with ASD. We replicated findings of no relationship between TL and core ASD symptoms, but add new findings of relationships with sensory symptoms. Further, we demonstrate TL is more tightly coupled with cognition in parents, which is concerning for cognitive aging outcomes in affected individuals with reduced TL at young ages. We observed a surprising correlation between longer TL and greater aloof traits in parents, which may reflect a protective mechanism to social stress. Further research is warranted to determine if TL is both a biological mechanism of symptoms in individuals with ASD and a potential treatment target.

272 **214.272** The Autism Speaks Mssng Whole Genome Sequencing Precision Medicine Resource

***S. W. Scherer**[1,2], S. Walker[1], J. Howe[1], R. K. Yuen[1], D. Merico[3], M. Bookman[4], B. Thiruvahindrapuram[1], J. Whitney[1], R. V. Patel[1], B. Trost[1], E. J. Higginbotham[1], Z. Background:
Autism Spectrum Disorder (ASD) is a highly heterogeneous disorder, both in clinical presentation and genetic architecture. There are hundreds of loci associated with ASD with multiple types of rare and common genome-wide variation contributing risk.

Objectives:

We are performing whole-genome sequencing (WGS) of families with ASD to build a resource, named MSSNG, to enable the sub-categorization of phenotypes and underlying genetic factors involved.

Methods:

We have created a cloud database containing WGS data and clinical information which is accessible through an internet portal with controlled access. We are soon releasing data to bring the total number of genomes to over 10,000, including new subjects who are part of the Ontario POND-network, The Quebec Transforming Care Consortium (TACC), the British Columbia iTARGET project, the Autism Phenome Project, the Baby Siblings Research Consortium and Autism Speaks AGRE samples (including The Autism Simplex Collection (TASC)). Data are available for single nucleotide variants (SNVs), small insertion/deletions (indels) and copy number variants, with structural variants (SV; including short repeats), and mitochondrial variants also coming.

Results:

From our first analysis, 61 genes and ~35 copy number variation (CNV) loci were implicated as contributing to ASD risk based on *de novo* or X chromosome single nucleotide variants (SNVs) and small indels, with 18 of these genes identified for the first time. Subsequently, we have focused on the identification and characterisation of smaller CNVs and SVs in 7,231 genomes. We have detected CNVs >1 kb in size using our established pipeline combining ERDS and CNVnator, or from Complete Genomics data, and we are now adding SVs detected using algorithms Manta, LUMPY and DELLY. Of the first 3,427 affected subjects analyzed, 6.6% carry an ASD-risk rare CNV, falling into one of four categories: chromosome abnormalities (0.8%), large CNVs >3Mb (0.9%), CNVs corresponding to known genomic disorders (3%) and deletions at known ASD-susceptibility genes or loci (1.9%). A further 1.7% of subjects have rare duplications impacting ASD-risk genes. All other public exome and WGS data is being incorporated into our MSSNG framework genome-wide data through comparative meta-analysis. To enable functional analysis studies of candidate variants, we have generated 63 iPS derived neuronal lines from individuals with ASD, and their familial controls, and another 25 lines using CRISPR modelling in an isogenic line. We have also consented 308 families (more coming) for connection of participants into local health medical record databases, with the aim of searching for environmental influences, and potential medical trends in the data.

Conclusions:

The Autism Speaks MSSNG project combines high quality WGS data with phenotype information to facilitate researchers of all backgrounds in studies of the genetic architecture of ASD. Further updates expected for the MSSNG resource include improved portal functionalities, phenotype querying capabilities, re-analysis of data with hg38, and inclusion of epigenetic data. Additionally, a subset of the genomes will be included in worldwide data sharing via the Beacon Network.

273 **214.273** Utilizing Extended Families to Prioritize Autism Risk and Protective Variants from Whole Exome Sequencing

M. L. Cuccaro[1], *A. J. Griswold*[1], *L. Gomez*[1], *D. Van Booven*[1], *H. N. Cukier*[1], *E. R. Martin*[1], *J. P. Hussman*[2] *and M. A. Pericak-Vance*[1], *(1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)Hussman Institute for Autism, Catonsville, MD*

Background: Massively parallel sequencing in autism (AUT) has focused primarily on trio cohorts for identification of de novo loss of function protein coding variants. Extended, multiplex families, with at least one cousin pair with AUT, offer a unique and powerful tool to identify potential new AUT genetic risk loci using identical by descent (IBD) filtering. These pedigrees are likely to carry AUT susceptibility loci of moderate to high effect that may not be identified through de novo identification strategies. Furthermore, using typically developing siblings from these same families we can refine these risk candidate genes to only those with strong effects and identify potentially protective genes segregating in the families.

Objectives: Our study applies WES to extended, multiplex families likely to carry rare, partially penetrant inherited alterations. We hypothesize that separate IBD analysis among AUT individuals and typically developing individuals in these pedigrees will define genomic regions of shared AUT risk or protection and allowing identification of shared risk or protective variants.

Methods: We performed WES on at least two ASD individuals and two typically developing siblings across 14 extended families. Sequencing was performed on the Illumina HiSeq2000 and analyzed through current best practice pipelines including BWA-MEM alignment, quality recalibration by GATK, and variant calling with the GATK HaplotypeCaller. Annotations were applied with ANNOVAR. We determined IBD regions using existing whole genome genotyping data and the MERLIN package first using shared regions in ASD individuals in each family to identify shared risk variants, and then again with non-ASD individuals to identify protective regions. Variants were selected by heterozygous IBD sharing in all ASD (risk) or non-ASD (protective) individuals per family, protein coding effect (non-synonymous), and population frequency (< 5% in the ExAC database). Priority was further determined by removing variants shared with either non-ASD siblings (risk) or ASD siblings (protective).

Results: Filtering for shared risk variants in IBD regions identified 4-123 variants per family and for protective variants yielded 0-96 per family, depending on pedigree structure and resulting IBD region size. After filtering potential risk variants shared by non-AUT individuals there were 0-59 risk variants per family. Similarly, filtering out potential protective variants shared by AUT individuals revealed 0-30 protective variants per family. For risk gene identification, only one gene, *FAAP100* (*C17orf70*), passed all filtering criteria in more than one family. It is highly expressed in the cerebellum though its neuronal function is unknown. Individual families carried risk variants in several high evidence AUT candidate genes (defined by SFARI Gene database) including *ANK2, CIC, NF1, SCN7A,* and *WDFY3*. For protective gene identification, again only a single gene, *SCN9A*, was shared between non-AUT individuals only in more than one family. It is expressed primarily in the hypothalamus and testes and interestingly has been associated with protection against pain and neurodegeneration.

Conclusions: By studying these unique pedigrees, we have identified novel DNA variations related to AUT and demonstrated that exome sequencing in extended families is a powerful tool for ASD risk and protective gene discovery.

Poster Session
215 - Neurological findings
5:30 PM - 7:00 PM - Room: 710

274 **215.274** Simple Reaction Time Performance in Autism Spectrum Disorder and Neurotypical Subjects

M. Mazzucchelli[1], *V. Gariboldi*[1], ***G. Valagussa***[1,2], *C. Perin*[1], *C. Cerri*[1] *and E. Grossi*[2], *(1)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

Background: The speed with which an individual is able to make a simple motor response to a perceived stimulus may fairly be regarded as a significant index to his basic level of perceptual-motor integration. Developmental studies on reaction time in subjects with a neurotypical (NT) development report a decrease in simple reaction time (SRT) with increasing age and a strong correlation between upper and lower limb simple reaction time tasks. No studies are available in this regard in Autism Spectrum Disorder (ASD) subjects.

Objectives: The aims of this study are: 1) to assess developmental changes in the speed of a simple reaction at the lower and upper limb in ASD children as they age; 2) to assess the correlation between upper and lower limbs SRT in ASD children; 3) to assess the correlation between lower limb SRT and ankle dorsiflexors muscles strength in ASD children; 4) to compare the results with the same data obtained in a sample of 243 NT

subjects.

Methods: The study sample included 12 ASD subjects (10 males; age range 5 -18 years). The ASD subjects were diagnosed with autism according to the DSM V criteria, confirmed through ADOS-2 and under observation at our Institute. SRT was measured in milliseconds using a hand-held electronic timer and a light as the stimulus and finger or foot lever to trigger responses. The testing of ankle dorsiflexion force was done using a footplate attached to a spring gauge. All the tests employed have been validated for the study of sensorimotor components of balance into the Fall Screen Assessment System.

Results: At variance with NT group we found no significant correlation between both upper and lower SRT and age in ASD study group (upper limb: R Pearson=-0.056, p=0.863; lower limb: R Pearson=-0.065, p=0.841) and no correlation between lower limb SRT and ankle dorsiflexors muscles strength. Instead, similarly to NT group a significant positive correlation between upper and lower limb reaction time tasks was found (ASD: R Pearson=0.819, p=0.001; NT: R Pearson=0.666; p=0.000).

Conclusions: This is the first study that analyses upper and lower limbs SRT developmental variability and its correlation with ankle strength performance in ASD subjects. The absence of a developmental improvement in SRT and the impairment in lower limb SRT tasks found in ASD subjects point out a disorder of sensorimotor integration in ASD subjects potentially responsible for postural control imbalance.

275 **215.275** Simple Reaction Time and Postural Control in Autism Spectrum Disorder Subjects

*M. Mazzucchelli[1], V. Gariboldi[1], **G. Valagussa**[1,2], C. Perin[1], C. Cerri[1] and E. Grossi[2], (1)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

Background:
Reaction Time (RT) has been used as biomarker of cognitive performance and of trans-diagnostic phenotype in Autism Spectrum Disorders (ASD). It is also well known that RT is an important component of effective postural control and balance. In this regard few studies have examined the relationship between static and dynamic balance and Simple Reaction Time (SRT) in neurotypical (NT) children and adolescents. No studies are available in this regard in ASD subjects.

Objectives: The three aims of this study are: 1) to assess SRT in a ASD sample 2) then measure the correlation between lower limb SRT and sway tests (ST), maximal balance range test (MBRT) and coordinated stability test (CST) in ASD children; 3) to compare the results with the same data obtained in a sample of 243 NT subjects.

Methods:

The study sample included 12 ASD subjects (10 males). The ASD subjects were diagnosed with autism according to the DSM V criteria, confirmed through ADOS-2 and under observation at our Institute. SRT was measured in milliseconds using a hand-held electronic timer and a light as the stimulus and the activation of a foot lever for responses. We conducted all the postural control tests using a sway meter that measures displacements of the body at waist level. ST is the evaluation of anterioposterior and mediolateral sway as the subject attempts to stand as still as possible for 30 seconds; ST was performed in four different conditions: on the floor with open- eyes, on floor with their eyes closed, on a foam rubber mat with open-eyes and on a foam rubber mat with their eyes closed. MBRT measures the maximum distance traveled from the total forward and backward excursion. CST is the evaluation of errors made by the subject in moving the pen of the sway meter on a predefined track. All the tests employed have been validated for the study of sensorimotor components of balance into the Fall Screen Assessment System.

Results:

The mean age of ASD subjects was 11.67y (SD 4.08y; range 5-18y). Seven out of 12 ASD subjects (58,3%) showed SRT values above the Reference Intervals age related of NT children; four ASD subjects (33,3%) were in and those of 1 subject (8,3%) was lower. We found no significant correlations between SRT and ST values in all the four conditions and between SRT and both MBRT and CST values, while in the NT reference group there was a significant correlation between SRT and ST in 3 of 4 conditions. In the same group SRT performance significantly correlated also with MBRT (R Pearson=-0.245; p=0.000) and with CST (R Pearson=0.644; p=0.000).

Conclusions: This is the first study that analyses correlation between lower limb SRT and postural control performance in ASD subjects. In contrast with results obtained in NT subjects, lower limb SRT are not correlated with sway tests, MBRT and CST values. These findings confirm the presence of deficits of sensorimotor integration and therefore impairment in postural control in ASD children.

276 **215.276** Understanding Early Relationship between Autism Spectrum Disorder, Cognitive Impairment and Epilepsy in Infants with Tuberous Sclerosis Complex: Preliminary Results from the Epistop Project

***A. Benvenuto**[1], R. Moavero[1], M. Siracusano[2,3], L. Emberti Gialloreti[2], E. Aronica[4], A. Jansen[5], F. Jansen[6], S. Jozwiak[7], K. Kotulska-Joswiak[8], D. Kwiatkowski[9], L. Lagae[10] and P. Curatolo[1], (1)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (2)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (3)University of L'Aquila, Italy, L'Aquila, Italy, (4)Academisch Mediche Centrum, University of Amsterdam, Amsterdam, Netherlands, (5)Vrije Universiteit Brussel, Brussels, Belgium, (6)University Medical Center Utrecht The Netherland, Utrecht, Netherlands, (7)Children's Memorial Health Institute, Warsaw, Poland, (8)Neurology and Epileptology, Children's Memorial Health Institute, Warsaw, Poland, (9)Brigham and Women's Hospital, Harvard Medical School, Boston, MA, (10)University of Leuven, Leuven, Belgium*

Background: Tuberous sclerosis complex (TSC) is a rare genetic multisystem disorder that confers a high risk of early neuropsychiatric conditions. Epilepsy is one of the major issues in TSC and is considered a potential risk factor for autism spectrum disorders (ASD) and developmental delay (DD), but the relationship between autistic traits, epilepsy, and cognitive functioning remains poorly understood. The EPISTOP project is a multi-center prospective European study focused on discovering correlation between epileptogenesis and neurodevelopmental disorders in TSC.
Objectives: The aim of EPISTOP was to compare neurodevelopmental outcome of the infants according to epilepsy variables and timing of antiepileptic treatment; we compared preventive group, in which antiepileptic treatment was started immediately after the first appearance of EEG abnormalities, versus conservative group, in which antiepileptic treatment was administered after the appearance of (sub)clinical seizures.

Methods: 97 TSC subjects were prospectively followed from 6 to 24 months of age with neuropsychological assessment (Bayley Scales of Infant Development and Autism Diagnostic Observation Schedule), in order to evaluate early interplay between developmental level and ASD risk. We

correlated neuropsychological outcome at 24 months with epilepsy variables including history and type of seizures, age at seizure onset/first abnormal EEG, and finally according to type (conservative versus preventive) and response to treatment. Comparisons between groups were performed with two-sample t test, ANOVA models, and Spearman's correlations. An alpha level of 0.05 was used for all statistical analyses, which were performed using SPSS v.23.0 (IBM Corp., Armonk, NY, USA).

Results: Data for the final analysis were available for 82 patients. A cognitive developmental quotient higher than 80 at 6 months of age was able to predict a positive developmental trajectory towards normal developmental level and no ASD symptoms at 2 years of age (p =0.025). ASD rate was significantly higher in patients with a history of epilepsy (p=0.017; risk rate or RR: 6.0), particularly if the onset of seizures was in the first 12 months of age (p=0.025, RR: 2.7). An onset of seizures in the first year of life was also associated with a high risk for DD/cognitive impairment (p=0.001, RR: 4.6). According to type of treatment, in the preventive group 65% of children had normal development at age 24 months, compared to 47% in the conservative group. ASD rate (with or without associated DD) was similar in the two groups (conservative 33%, preventive 30%), but DD without ASD was significantly lower in preventive group compared to conservative group (4% versus 21%; RR 0.6).

Conclusions: ASD presence in TSC was inextricably linked with cognitive level and severe, early onset epilepsy, but these correlations are not sufficient to explain the complex underlying mechanisms of ASD in TSC model. A rigorous, prospective follow-up with EEG and formal developmental assessment is mandatory to identify those infants and children at risk for developmental delay and/or ASD, in order to ensure early referral for parent-mediated implementation and training of cognitive skills and to potentially minimize the impact of these risk factors on ASD outcome.

277 **216.277** Pancreatic Replacement Therapy with CM-at Is Associated with Reduction in Maladaptive Behaviors in Preschoolers with Autism.

*M. F. Heil[1], **D. A. Pearson**[2], R. Hendren[3], S. R. Raines[4] and J. Fallon[1], (1)Curemark, LLC, Rye, NY, (2)McGovern Medical School, Univ. TX Health Sci Cntr-Houston, Houston, TX, (3)Psychiatry, University of California, San Francisco, San Francisco, CA, (4)2b Analytics, LLC, Wallingford, PA*

Background:
Many children with autism exhibit self-restrictive dietary patterns, particularly avoidance of protein. Previous studies by our group suggest that this behavior may reflect digestive impairment associated with abnormally low levels of the enzyme chymotrypsin in some children with autism (e.g., Heil et al, 2014). Chymotrysin is needed to digest protein, and a lower endogenous level of it results in a reduced ability to break down protein into its component amino acids. As a result of this deficiency, there might be lower levels of amino acids available to synthesize new proteins such as neurotransmitters--which in turn might ultimately affect behavioral status. This deficiency would be particularly problematic in rapidly growing preschoolers. If this digestive insufficiency could be normalized with dietary enzymatic replacement therapy, it may result in improved behavioral function in children with autism.

Objectives:

The objective of this study was to ascertain whether or not behavior (e.g., symptoms of irritability, hyperactivity) in preschoolers with autism could be improved with CM-AT, a pancreatic enzyme preparation.

Methods:

Preschoolers (n=190) ages 3-5 years old, meeting DSM-IV-TR criteria for Autistic Disorder, participated in this randomized, placebo-controlled, 12-week clinical trial of CM-AT. Children entering the trial were required to have a score of ≥11 on the Aberrant Behavior Checklist-Irritability scale (ABC-I). Following a 2-week placebo run-in, children were randomized to either CM-AT (n=92, 71 boys), which was delivered as granules sprinkled on food, or to placebo (n=98, 79 boys), which consisted of visually identical inert sprinkles. The primary outcome measure for this trial was ABC-Irritability (ABC-I). Here we report all the ABC data in this 12-week trial.

Results:

Mixed model repeated measures (MMRM) procedures revealed that children receiving CM-AT (relative to those receiving placebo) demonstrated significant reductions in Irritability (ABC-I: *p*=.038); Hyperactivity (ABC-HA: *p*=.049; Inappropriate Speech (ABC-IS: *p*=.015) over the 12 weeks of the trial. Additional MMRM analyses were performed examining treatment response in a subset of preschoolers (n=69) with higher levels of irritability (ABC-I ≥18+) and greater overall clinical severity (CGI-S≥4) at baseline. In this more severely affected subgroup, the 29 preschoolers who received CM-AT (relative to the 40 who received placebo), the significance of the treatment effects for Irritability and Hyperactivity were even greater than those found in the overall sample (ABC-I: *p*= .022; ABC-HA: *p*=.027). Although reductions in Lethargy/Social Withdrawal (ABC-L/SW) and Stereotypic Behavior (ABC-S) were also noted during the course of this 12-week trial for both the overall sample and for the more severe subsample, no statistically significant treatment effects emerged for these symptoms in this 12-week treatment trial.

Conclusions:

These results suggest that even within the short timeframe of 12 weeks, children with autism who received pancreatic enzymatic replacement therapy with CM-AT demonstrated reductions in maladaptive behaviors commonly associated with autism (e.g., irritability, hyperactivity, inappropriate speech). These effects were even more pronounced in a subset of preschoolers with autism who had higher levels of initial irritability and global clinical ratings of maladaptive behavior. Long-term effects of CM-AT are continuing to be studied in an open label follow-up study.

278 **217.278** A Systematic Review of Play Based Intervention Effectivity for Children with Autism.

*H. Swaab[1], I. A. van Berckelaer-Onnes[2], W. A. Ester[3] and **L. Dijkstra-de Neijs**[4], (1)Leiden University, Leiden, Netherlands, (2)Faculty of Social Sciences, Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (3)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands, (4)SARR Expert Center for Autism, Lucertis Child- and Adolescent Psychiatry, Parnassia Group, Rotterdam, Netherlands*

Background: Autismspectrumdisorders (ASD) are an urgent global mental health problem with a worldwide estimated prevalence of one in 132 individuals. Studies show that up to 64% of the people with ASD have comorbid problems. Parents of children with autism display more mental distress. Children with ASD with co-morbid problems in combination with parental distress influences the parent-child relationship and may significantly interfere with the overall life outcome of people with ASD. Play therapy has been proven effective for children who experience mental health problems. The development of play within children with ASD differs from other children. There are few evidence based play treatments for children with ASD.

Objectives: To determine which forms of play therapy and/or play based interventions are effective on behavioural problems in children with an ASD and their parents.

Methods: A systematic literature search following the PRISMA guidelines. Studies were included if they reported quantitative data on any type of 'play therapy' or 'play based intervention' used within a population of 'children' with 'ASD'.

Results: We identified 69 studies fulfilling our search criteria constituting of 13 RCTs, 54 quasi experimental studies and 2 case studies. Positive outcomes regarding diminished behavioural problems and increased social skills in children with ASD were substantiated by randomized controlled trials (RCT) in seven play based interventions: 1) PLAY project, 2) Developmental, Individual-differences & Relationship-based model(DIR)/Floortime, 3) Lego® therapy, 4) Joint Attention Symbolic Play Engagement Regulation (JASPER), 5) Early Start Denver Model (ESDM), 6) 1-2-3 project and 7) Pivotal Response Treatment (PRT). Another three play based interventions showed positive results through quasi experimental research: 1) Theraplay, 2) Child Centered Play Therapy (CCPT) and 3) Parent-Child Interaction Therapy (PCIT). A large variation in treatment goals as well as in outcome measurements was found within all ten play based interventions. The main outcome measurements constituted of reduced withdrawn social behaviour or tantrums, increased social skills such as joint attention and eye contact and improved language skills.

Conclusions: Although a vast amount of studies regarding play based interventions for children with ASD are available, only a minority comprise RCT's. Future research should focus on evaluating the effectiveness of play based interventions for children with ASD through RCT's, in which parental distress and the parent-child relationship are included to improve the over all life outcome for people with ASD and their parents.

279 **217.279** Are Rates of Autism and Autism Symptoms Raised Among Children with Neurofibromatosis Type-1?

***E. Fombonne**[1], H. Morotti[2], S. Mastel[3], R. Barnard[4], K. Keller[5], T. Hall[2], A. Barnes[6] and B. J. O'Roak[7], (1)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR, (2)Oregon Health & Science University, Portland, OR, (3)Institute on Development and Disability, Oregon Health and Science University, Portland, OR, (4)Oregon Health and Science University, Portland, OR, (5)Department of Molecular and Medical Genetics, Oregon Health and Science University, Portland, OR, (6)Knight Cancer Institute, Portland, OR, (7)Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR*

Background:

NF1 is associated with several developmental and behavioral challenges including ADHD, and intellectual/learning disabilities. It was recently reported that up to 50% of NF1 subjects also meet diagnostic criteria for autism spectrum disorder. However, it is unclear if the increase in autism diagnosis and symptomatology is accounted for by confounding psychiatric features, especially ADHD symptoms.

Objectives:

This study reexamined the association between ASD diagnosis, ASD symptomatology, and NF1.

Methods:

We selected participants aged 5-13 with NF1 (mean age = 9.2; 50% male). Control subjects were matched on age and sex on each participant in a 4:1 ratio to create two control groups of 180 ASD subjects and 180 typically developing (TD) siblings. Participants were evaluated with the CBCL, NICHQ Vanderbilt, Vineland-II, SRS-2, RBS-R, and SCQ. We performed an EPIC search on ICD-10 diagnoses of NF1 and PDD; additionally, medical records of NF1 subjects were abstracted. Comparisons were also performed with data published by the International NF1-ASD Consortium.

Results:

In the OHSU EPIC database, there were 968 patients with an NF1 diagnosis, of whom 20 (2.07%) had a PDD diagnosis and 85 (8.8%) had an ADHD diagnosis.

On measures of autistic symptomatology, the NF1 group scored significantly lower than the ASD group, on both SRS-2 total score (55.8 vs 81.1; p = .001), SCQ total score (6.1 vs 20.6; p = .001) and RBS-R total score (10.4 vs 27.6; p = .001). On the two available measures of autism symptoms in the TD group, TD subjects scored lower than NF1 participants (SRS-2: 44.6 vs 55.8; p = .001; SCQ: 6.1 vs 1.9; p = .001), though the magnitude of the differences were small in comparison to the NF1/ASD contrast. Both groups' means fell under the published thresholds on these two instruments. Moreover, differences were attenuated on all measures when 11 NF1 participants with a comorbid ADHD diagnosis were removed from analysis.

The same pattern emerged with the total externalizing and internalizing scores of the CBCL, with the NF1 group falling between the ASD and TD groups. NF1 participants did not differ from TD siblings for adaptive behavior on the Vineland ABC (99.7 vs 102.3; NS), Daily Living Skills (102.7 vs 100.4; NS), and Socialization (104.8 vs 101.4; NS). However, NF1 subjects had significantly lower scores than TDs on the Vineland Communication score (97.0 vs 106.7; p = .001) although their mean scores were very close to the population mean and were significantly higher than in the ASD group (97.0 vs 75.3; p = .001).

Compared to published consortium data, the mean SRS scores for NF1 were slightly lower (55.8 vs 58.2); remarkably, both means fell well within the normal range of SRS norms.

Conclusions:

This study does not support an association of ASD diagnosis with NF1. There was no evidence of an increased rate of clinically diagnosed ASD in our sample or hospital electronic medical records. Our NF1 sample showed mild elevation of autistic symptomatology on standardized measures, but average scores remained below published cutoffs on these measures.

280 **217.280** Early Identification in Autism: Subtypes Based on Child, Family, and Community Characteristics

A. Wallisch[1], *L. Little*[2], *B. Salley*[3], *D. Irvin*[1], *E. Dean*[4], *W. Dunn*[5] *and J. Poggio*[6], *(1)University of Kansas, Kansas City, KS, (2)Rush University, Chicago, IL, (3)Pediatrics, University of Kansas Medical Center, Kansas City, KS, (4)University of Kansas Medical Center, Kansas City, KS, (5)University of Missouri, Columbia, MO, (6)University of Kansas, Lawrence, KS*

Background: The American Academy of Pediatrics (AAP) screening guidelines highlight the importance of listening closely to parent concerns as an effective strategy to identify children earlier (Johnson & Meyers, 2007). While the AAP guidelines have led to increased rates of developmental screenings and earlier identification of ASD (e.g., Radecki, Sand-Loud, O'Connor, Sharp, & Olson, 2011), many children, especially those considered underserved (i.e., low-income, rural, or racial/ethnic minorities), still receive later diagnoses. Given the immense heterogeneity across autism spectrum disorders (ASD), we investigated subtypes of children with ASD based on parent concerns and socio-demographics.
Objectives: Research questions included: 1) among children with ASD, how do early parent concerns, child (i.e., age and gender), family (i.e., race/ethnicity, socioeconomic status [SES]), and community (i.e., provider access) characteristics group by subtypes, and 2) to what extent do subtypes of children with ASD differ by chronological age at the diagnostic evaluation?

Methods: We performed a secondary analysis with data drawn from a medical university child diagnostic center. The sample included children (n=712) 12 months- 12 years (M=66.68 months; SD= 34.28) who eventually received a diagnosis of ASD. We examined intake information completed by parents prior to the diagnostic evaluation including: 1) parent concerns, 2) child's age, 3) child gender, 4) family SES, 5) race/ethnicity, and 6) access to service providers. For parent concerns, we coded these statements into six categories (adapted from Ozonoff et al., 2009), including: 1) behavior/temperament, 2) cognitive development, 3) speech/communication, 4) social interactions, 5) stereotyped behaviors, and 6) medical. Coders examined percent agreement with 20% of the dataset and achieved 89%. For the first research question, we used latent class analysis (LCA). For research question two, we performed a Kruskal-Wallis H-Test.

Results: After comparing the LCA fit statistics (i.e., Akaike Information Criterion, Bayesian Information Criterion, Adjusted Bayesian Information Criterion, Vuong-Lo-Mendell Rubin, Lo-Mendell-Rubin, entropy) of a two to seven class solution, results revealed a five-class solution fit best. Two subtypes were identified younger (i.e., approximately 3.5 years of age) and were differentiated by communication and medical concerns. One of these younger subtypes included non-white, Hispanic children utilizing Medicaid. Another subtype was identified around 5.5 years and was differentiated by stereotyped and by developmental parent concerns. Lastly, two subtypes were identified at an older age (i.e., approximately 9 years of age) with either cognitive concerns, or social and behavior concerns. One of the oldest subtypes was characterized by females with ASD.

Conclusions: By understanding ASD subtypes based on parent concerns from diverse socio-demographics, we may inform universal screening procedures. Our study suggests that children with speech/communication parent concerns are most likely identified earlier regardless of race, ethnicity, or SES. Whereas, children with social and behavior parent concerns, as well as females were diagnosed later. Future research should examine the distinct subtypes of females with ASD. While certain social and behavior concerns are acceptable during early years of childhood, more research is needed to determine methods to distinguish these types of parent concerns earlier.

281 **217.281** Daily Dental Care, Dental Office Experiences, and Oral Health in Underserved Children with ASD

R. M. Fenning[1,2], *R. steinberg Epstein*[3], *E. Butter*[4], *K. Hammersmith*[4], *K. McKinnon-Bermingham*[5,6], *M. Norris*[4], *J. M. Moffitt*[2], *D. Coury*[4], *F. Lu*[7], *E. Macklin*[7] *and K. Kuhlthau*[7], *(1)Center for Autism, Child and Adolescent Studies, California State University, Fullerton, Fullerton, CA, (2)Pediatrics, The Center for Autism and Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (3)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (4)Nationwide Children's Hospital, Columbus, OH, (5)CalState Fullerton, Irvine, CA, (6)Cortica Advanced Neurological Therapies for Autism, Irvine, CA, (7)Massachusetts General Hospital, Boston, MA*

Background: Dental care represents one of the most commonly reported unmet healthcare needs for children with ASD, a group vulnerable to excessive plaque, caries, and oral infections. Low socioeconomic and racial/ethnic minority status may further compound this risk, but limited research has focused on oral health in underserved families of children with ASD

Objectives: The present report is drawn from an ongoing clinical trial focused on enhancing daily dental hygiene and oral health outcomes in underserved children with ASD whose parents reported difficulty with dental care. Baseline data are presented to characterize in-home dental care, dental office visit experiences, and oral health status in this unique population, and to examine preliminary associations between health behaviors and oral health outcomes.

Methods: Participants included 112 families of children with ASD (*M* = 7.5, *SD* = 2.7, range = 3.1-13.3yrs) who reported difficulty with dental care. Families exhibited racial and ethnic diversity (45% Non-Caucasian, 39% Hispanic/Latino), and all were underserved (Medicaid-eligible). Children presented with a range of developmental and behavioral functioning (16% with ID; 61% clinical CBCL Total), and ASD symptom severity (ADOS-2 *M* = 7.3, *SD* = 1.8). Parents reported on dental history and in-home dental hygiene. A dental visit yielded standardized oral health measures and dentist ratings of child behavior.

Results: Fifty percent of children had participated in a dental visit within the past year; 20% had never been to a dentist. For the latter group, parental concern about child behavior was the most commonly reported barrier. Of children with a previous dental visit, 56% experienced prior use of physical restraint and 43% received pharmacological intervention. Only 44% of parents described their child's last dental visit as complete. Regarding in-home dental hygiene, parents reported completing child tooth brushing at least once daily an average of 5.1 (2.4) days/week and twice daily an average of 3.1 (2.8) days/week. Fewer families reported attempting (40%) and completing (25%) flossing. Most families reported problems engaging their children in tooth brushing (75%) and flossing (73%). Thirty-one percent of children presented with untreated dental caries (decayed teeth *M* = .92, *SD* = 1.8), which exceeds general population averages, and 52% were rated by study dentists as displaying negative responses to the exam. Interestingly, higher frequency of at least once-daily tooth brushing was associated with poorer quality oral health as measured by the decayed, missing, and filled teeth index, $r = 0.21$, $p < .05$.

Conclusions: Findings reveal heightened risk for unmet dental needs and poorer quality oral health in our sample of underserved children with ASD. The inverse association between dental hygiene and oral health suggests that parents may be attempting to respond to children's increased needs through at-home care. However, parents also reported significant difficulty engaging children in daily dental hygiene, which may result in compromised quality. Follow-up analyses will focus on identifying child and family factors predictive of children's participation in dental care and oral health status. Enhanced understanding of health behaviors and dental experiences is critical to advancing service models and care for this population.

282 **217.282** Do Fetal Biometrics Predict Toddler Measures of Autistic Traits or Language Development?

E. Aydin[1], *R. Holt*[1], *C. Allison*[2], *R. Hawkes*[3], *D. Chaplin*[3], *A. Tsompanidis*[4], *T. Austin*[5] *and S. Baron-Cohen*[2], *(1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, (4)Department of Psychiatry, 1991, Cambridge, United Kingdom, (5)University College London, London, United Kingdom*

Background: The prenatal period is a critical time for development. To date, research has not examined differences in fetal development beyond using the standard measures taken during the ultrasound scan. This is largely due to research being conducted retrospectively, using measures taken at the time of birth or using growth measures from medical ultrasounds. In the Cambridge Ultrasound Project (CUSP) we prospectively measured not just standard fetal markers of fetal growth but also a novel fetal biomarker, anogenital distance (AGD) since this is correlated with prenatal androgen exposure, and androgens are elevated in pregnancies where the fetus is diagnosed with autism postnatally.

Objectives: To test whether markers for fetal growth and novel biomarkers, including AGD, predict autistic traits and language development between 18-20 months of age.

Methods: The sample comprised 150 singleton pregnancies. At the time of abstract submission, 50 of these had completed data (28 males, 22 females). Prenatal ultrasounds were conducted from a research ultrasound between 26-30 weeks pregnancy using a GE 8 Expert Ultrasound system. Fetal head circumference (HC), cerebellum width, and ventricular atrium (VA) measures were taken. HC and cerebellum width were standardised according to UK fetal biometry reference charts. Additionally, anogenital distance (AGD) was measured from the centre of the anus to the base of the scrotum in males, and to the posterior convergence of the fourchette in females. For AGD no biometry reference charts exist, therefore a composite score was created controlling for estimated fetal weight (EFW) for AGD to standardise this measure. Parents were asked to complete the Quantitative Checklist for Autism in Toddlers (Q-CHAT) online when their infant was between 18- and 20-months old, along with the Communication Development Inventory (CDI) as a measure of vocabulary development. Standardised fetal biometry scores were examined against Q-CHAT and CDI scores at 18-20 months. Analysis was carried out separately for each growth parameter and sex. By the Spring, all 150 participants' complete data will be available.

Results: There was currently no significant effect of fetal biomarkers measured between 26-30 weeks gestation, including AGD on Q-CHAT or CDI at 18-20 months.

Conclusions: These preliminary findings suggest there is no association between fetal physical developmental and toddler measures of autistic traits or language development. This may be because the sample is currently underpowered, but the current data is only about one third of the final sample. Complete data will be reported in the poster as the infants turn 18 months. This study will continue to follow these infants' development until they are 24-months old to observe subsequent physical and behavioural development and re-administer the Q-CHAT at this time.

283 **217.283** Dreams in Children with Autism Vs ADHD: Content Recall and Frequency of Emotions

*K. H. Nguyen[1], É. Soucy-Savard[1], M. Chicoine[2] and **R. Godbout**[3], (1)Université de Montréal, Montréal, QC, Canada, (2)Sleep Laboratory and Clinic, Hôpital en santé mentale Rivière-des-Prairies, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Psychiatry, Université de Montréal, Montréal, QC, Canada*

Background:
The Autism Spectrum disorder (ASD) and the Attention Deficit/Hyperactivity (ADHD) disorder are two highly comorbid neurodevelopmental disorders. Individuals with any of these diagnoses show atypical cognitive functioning, including emotional processing when compared with typically developing (TD) counterparts. Despite a lack of systematic studies, dreams in ASD and ADHD children are thought to differ from those of TD children in various ways. Indeed, children with ASD often struggle to distinguish between mental states of dreaming and thoughts. Moreover, their dreams are more likely to be based on real-life events and thus may be perceived as concrete or realistic. On the other hand, dreams of children with ADHD contain more negative content such as physical aggression. However, their dreams frequency recall is similar to non-ADHD children. The study of dreams in these two groups of children could constitute an opportunity to better understand the physiopathology of neurodevelopmental disorders.

Objectives: The aims of the present study were to characterize the aspects of the manifest dream content in ASD and ADHD children. We also wanted to explore whether or not ASD and ADHD children differed on (1) the easiness to recall their dreams, (2) the cloudiness of dream recall, and (3) the frequency of four basic dream emotions which are sadness, joy, fear, and anger.

Methods: A total of 18 children diagnosed with ASD (11.7 ± 3.7 years, 14 boys) and 18 children diagnosed with ADHD (11.8 ± 3.3 years, 11 boys) filled a dream content self-report. Groups were compared on easiness to recall content (1 = never or impossible to recall, 5 = easy), cloudiness of recall (1 = really vivid, 5 = very cloudy) and the frequency of each of the four abovementioned emotions in their dreams (1 = never, 5 = always present). Results were compared with t-tests. We expected that recall, clarity and emotions would be decreased in the ASD group, while the negative emotions (sadness, fear and anger) would be more present in ADHD group.

Results: The children of the ASD group recalled less their dreams than the ones in the ADHD group (means ± s.d.: 2.0±1.0 vs 2.7±0.9; $t(29)=2.04$, $p<.05$). The content was more cloudy (3.9±1.1 vs 3.0±1.4; $t(29)=2.02$, $p<.05$) in the ASD group. There were no differences on the frequency of emotional items, both groups reporting rarely or seldom sadness, joy, fear, and anger.

Conclusions: Dream recall was less easy and less clear in children with an ASD when compared to ADHD. Comparable results on recall were published in ASD adults compared to a group of neurotypical individuals. The two groups of children did not differ on the frequency of emotional items, both displaying low scores. The samples were biased with more boys than girls, reflecting the clinical environment. The results possibly reflect an altered processing of emotional load in dreams of children with various neurodevelopmental disorders.

284 **217.284** Clinical Characteristics of Patients with Autism Spectrum Disorder Referred to a Pedopsychiatric Sleep Clinic

*N. Khebchi[1], M. Chicoine[1,2], D. Caron[1], C. Belhumeur[1], E. Martello[1] and **R. Godbout**[1,2,3], (1)Sleep Laboratory and Clinic, Hôpital en santé mentale Rivière-des-Prairies, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (2)Research Center, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, QC, Canada, (3)Psychiatry, Université de Montréal, Montréal, QC, Canada*

Background: Sleep disorders are frequent in children with an Autism Spectrum Disorder (ASD), with prevalence estimates as high as 80%. Even though sleep disorders increase diurnal symptoms and constitute a significant burden for the entire family, little is known about the clinical characteristics of these children.
Objectives: To describe the clinical characteristics of 250 ASD children referred to a specialized pedopsychiatric sleep clinic.

Methods: We reviewed the medical charts of 250 children with ASD referred to the sleep clinic of a child psychiatry hospital (mean age = 10.8±2.9 years, 76.8% boys). Specialty of the referring physician, diagnoses, medication and scores on the Children Sleep Habits Questionnaire (CSHQ) upon arrival, as well as sleep disorders after assessment at the clinic were extracted for analyses.

Results: The majority of patients were either referred by a pediatrician (42.8%) or a psychiatrist (38.4%). Half of patients (52.0%) had another diagnosis, the most frequent being Attention Deficit Hyperactivity Disorder (20.0%) and Intellectual Disability (12.0%). Upon arrival to the sleep clinic, 112 patients (44.8%) were taking prescribed medications, the most frequent being psychostimulants (18.8%), antipsychotics (12.4%), and antidepressants (10.4%); more specifically at bedtime, antipsychotics were the most frequent prescribed medication while 119 patients (47.6%) were taking melatonin. Among the 145 patients who filled the CSHQ, 138 (95.2%) reached or exceeded the clinical cut-off score of 41; the total observed scores ranged from 33 to 74. The most frequent confirmed sleep disorder was insomnia (21.6%), followed by parasomnias (9.6%): somniloquy (6.8%), bruxism (6.0%), restless legs syndrome or periodic limb movements during sleep (5.2% and 7.2%, respectively), obstructive and central sleep apnea (2.0% and 1.6%, respectively), somnambulism (2.0%) and confusional arousals (2.0%). Atypical EEG during sleep was found in 2.8%. There were no confirmed cases of hypersomnia or narcolepsy, circadian disorders or nocturnal eating disorders.

Conclusions: These data point towards salient features of ASD children presenting at a sleep clinic: most referring MDs are specialists, half the ASD patients have at least one additional psychiatric diagnosis, and the most frequent sleep disorder is insomnia. The proportion of patients with insomnia clearly exceeds the prevalence published for neurotypical children, while the prevalence of sleep apnea is similar to published prevalence in the general pediatric population. Antipsychotics being the most prescribed medication at bedtime is worrisome.

285 **217.285** Heightened Emotional Eating Behaviors in Children with Autism Are Modulated By Gender.

***E. Richard**, M. Nadeau, A. J. Wolff and G. L. Wallace, The George Washington University, Washington, DC*

Background: There is substantial risk for obesity among children and adults with autism spectrum disorder (ASD). There is emerging evidence that overeating behaviors are more common in ASD and might contribute to this obesity risk in ASD. To date, study of food approach behaviors in ASD has not included emotionally mediated eating. Furthermore, although phenotypic sex differences in ASD are gaining recognition, they have yet to focus on eating behaviors.
Objectives: Examine the roles of emotional valence and gender on eating in a sample of children with ASD and typically-developing (TD) children.

Methods: Parents of 231 (145 male) 4- to 17-year-old (mean=8.46, SD=3.31) children (153 with ASD and 78 TD) completed questionnaires about their children's eating habits. Parent ratings of emotional eating behaviors were obtained using the Eating in the Absence of Hunger questionnaire

(EAH) and Child Eating Behavior Questionnaire (CEBQ). Body mass index (BMI) was calculated using parent report of age, height, and weight using CDC norms. Specific subscales of the EAH included Negative Affect, and Fatigue/Boredom. Subscales of interest in the CEBQ were Emotional Over-Eating and Emotional Under-Eating.

Results: The ASD group had a significantly greater male:female ratio than the TD group (chi square=13.91, p<.001). Children with ASD were much more likely than TD children to exhibit over-eating behaviors linked to Negative Affect (t=5.33, p<.001) and Fatigue/Boredom (t=2.42, p=.01), and more likely to exhibit both emotional over-eating (t=7.19, p<.001) and emotional under-eating (t=5.65, p<.001). There were significant interactions between diagnosis and sex (Fs>4.23, ps<.05) for the over-eating related variables. While the neurotypical sample presented no gender differences on any of these measures (*ns*), females with ASD were significantly more likely than males with ASD to exhibit Negative Affect related over-eating (t=2.76, p=.006), Fatigue/Boredom related over-eating (t=2.86, p=.006), and general emotional over-eating (t=3.03, p=.003). Interestingly, there were no significant correlations (*ns*) between any of these eating-related ratings and BMI in the ASD group, but in the TD group BMI was significantly correlated with emotional over-eating (r=.28, p=.02).

Conclusions:

To our knowledge, this is the first study to examine emotional eating behaviors (overall and their potential gender differences) in children with ASD. Parents rated emotional eating behaviors as much more common in children with ASD than in TD children. Furthermore, emotionally mediated food approach behaviors were more common in girls than boys with ASD, while no gender differences in these behaviors emerged in the TD children. None of these eating-related metrics was significantly correlated with BMI in the ASD group. This suggests that the reason for eating, but not necessarily the quantity of eating, is more strongly linked to emotions in children with ASD than in TD children, and most strongly in girls with ASD. One possible interpretation is that the act of eating serves as a socially-acceptable "stimming" (self-comfort through self-produced sensory input) behavior. Because females with ASD are more likely to "camouflage," or to mimic neurotypical behavior (Rynkiewicz et al., 2016), albeit at considerable mental "cost," eating may be an especially desirable stimming outlet for females.

286 **217.286** Identifying Correlates of Adaptive Functioning in Children and Adolescents with Neurodevelopmental Disorders: A Pond Network Investigation

T. S. Park[1], *C. Hammill*[2], *P. Szatmari*[2], *S. Ameis*[3], *R. Schachar*[4], *E. Anagnostou*[5] *and M. C. Lai*[2], *(1)University of Toronto, Toronto, ON, Canada, (2)The Hospital for Sick Children, Toronto, ON, Canada, (3)The Margaret and Wallace McCain Centre for Child, Youth, & Family Mental Health, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Psychiatry, The Hospital for Sick Children, Toronto, ON, Canada, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Children and adolescents with neurodevelopmental disorders (NDDs), such as autism spectrum disorder (ASD) and intellectual disability (ID), have deficits in adaptive functioning that impair their ability to meet every day needs. Evidence consistently demonstrates IQ alone does not predict adaptive functioning in individuals with ASD and very few studies have examined correlates of adaptive functioning across NDDs. Given that NDDs may share underlying neurobiological mechanisms, better understanding of adaptive functioning and its correlates across NDDs can aid treatment planning and outcome monitoring.

Objectives: To examine the association of both NDD categorical diagnoses and dimensional NDD traits cutting across diagnoses on adaptive functioning.

Methods: Study data were obtained from the Province of Ontario Neurodevelopmental Disorders (POND) Network. Sample consisted of 2258 participants aged 3-18 years who are typically developing (n=364) or have clinical categorical diagnoses of ASD, ADHD, OCD, or ID. Behavioural variables-of-interest were obtained from psychometrically validated subscales of Social Communication Questionnaire (SCQ), Repetitive Behaviors Scale–Revised (RBS-R), Toronto Obsessive-Compulsive Rating Scale (TOCS), Strengths and Weaknesses of ADHD Symptoms and Normal Behavior Rating Scales (SWAN), and Child Behavior Checklist (CBCL). Adaptive functioning in conceptual, practical, and social domains was measured by the Adaptive Behavior Assessment System, 2nd Edition (ABAS-II). Elasticnet regularized regression was performed in R. False discovery rate correction was performed on approximate t-statistics to identify significant correlates across all regression outcomes.

Results: Having an ASD diagnosis and exhibiting higher levels of inattention were significant correlates of poorer adaptive functioning across all three domains. Severity of restricted interests in behaviour (measured by RBS-R) and repetitiveness (measured by SCQ) both had significant negative effects in conceptual and social domains.

Conclusions: An ASD diagnosis and dimensional traits of inattentiveness and repetitiveness are most associated with poorer adaptive functioning in children and youth. Increased understanding of adaptive functioning and specific correlates across NDDs can lead to better clinical assessment, tailored interventions, and improved transition to adulthood for children and adolescents with NDDs.

287 **217.287** Is Using Food As Reward in Children with Autism Associated with Increased Food Responsiveness?

A. J. Wolff, *E. Richard, M. Nadeau and G. L. Wallace, The George Washington University, Washington, DC*

Background:

Children with Autism Spectrum Disorder (ASD) are at elevated risk of being overweight and obese (Curtin et al., 2014). Parents use food commonly as a reward for their children's behavior; however, this is particularly common practice among children with ASD, through approaches such as applied behavior analysis. Research has found a correlation between parents who use food as a reward for their typically developing (TD) children and responsiveness to food and emotional eating (Farrow, 2016). This study seeks to be the first to examine this relationship in children with ASD and whether this relationship is modulated by picky eating status.

Objectives: Determine if parents of children with ASD use food as reward more often than parents of TD children and if food reward usage is correlated with food approach behaviors.

Methods:

Parents of children with ASD (n=153; M age = 8.9; 109 males) and TD children (n=78; M age = 8.3; 36 males) filled out online questionnaires about their children's eating habits and health. Parent utilization of foods as rewards was assessed using the Child Feeding Questionnaire (Birch et al., 2001) while food approach behavior was assessed using the Child Eating Behavior Questionnaire (CEBQ; Wardle et al., 2001). The CEBQ provides

measures of three relevant appetitive traits: food responsiveness, emotional overeating, and enjoyment of food. Picky eating was assessed using an item from the Eating Habits Survey (Wilde et al., 2012).

Results:

Parents of children with ASD reported greater usage of foods as rewards than parents of TD children (t=2.15, p<.05). Food reward utilization was positively correlated with two of the three food approach appetitive traits among all children with ASD: food responsiveness (r=.26, p=.001) and emotional overeating (r=.36, p<.001). However, when splitting the ASD group into picky eaters vs. non-picky eaters, the association with using food as reward and food responsiveness was accentuated in non-picky eaters (n=65; r=.37, p=.003) and disappears among picky eaters (r=.07, p=.54).

Conclusions:

Parents of children with ASD rated themselves as more likely to use food as a reward than parents of TD children, and the frequency of this food reward utilization was positively associated with food approach appetitive traits (i.e., food responsiveness and emotional overeating). Importantly, the link between using food as reward and food responsiveness was not found among picky eaters with ASD suggesting modulatory effects. Given the risks for overweight and obesity in ASD and its health consequences (e.g., cardiovascular health, diabetes, etc.), it is critically important to strive to use non-food-related methods of rewarding children with ASD, so as to try to lower the risk for developing appetitive traits that place children at risk for becoming overweight/obese.

288 **217.288** Medical Resident Needs for Training in Autism Spectrum Disorder: Comfort Level and Scope of Practice in Primary Care

J. F. Hine[1], *A. Swanson*[2], *P. Juárez*[1], *T. E. Foster*[3], *A. Dubin*[3] *and Z. Warren*[1], *(1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (3)Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE*

Background: The increased prevalence of autism spectrum disorder (ASD) and documented benefits of early intensive intervention have created a need for flexible systems for determining eligibility for autism-specific services. Given that most concerns for ASD initially present in primary care, pediatricians play an important role from first concerns to follow-up care. Unfortunately, many practicing pediatricians feel ill-equipped and uncertain assessing diagnostic risk and management of children with ASD.

Objectives: During development of a service system intervention introducing enhanced learning opportunities for residents in our pediatric residency program, we conducted the current study to assess the confidence of residents with regard to ASD screening, diagnosis, and follow-up care for ASD, in relation to other common concerns seen in primary care. This in turn helped identify potential training targets for our DBP rotation.

Methods: We designed an 18-item survey based on review of existing literature on physician and resident comfort level with a range of presenting concerns. Specific to ASD, residents were asked to rate the importance of education about ASD to their career, how strongly they felt that ASD concerns should fall within their scope of practice, their confidence in their ability to distinguish between ASD and other delays, their proficiency at using ASD screening tools, and their ability to connect families to specific services. Residents also completed rating scales assessing their confidence in providing care for patients presenting with ASD versus other common medical and developmental/behavioral concerns that present in primary care. Specifically, they rated their confidence in their ability to a) screen for and identify symptoms, b) communicate effectively about concerns, c) definitively diagnose, d) treat/manage symptoms, and e) facilitate follow-up care.

Results: Fifty-one residents completed REDCap surveys. Residents were significantly more confident in their skills with respect to caring for patients with other common concerns than for patients with ASD including significant differences in their perceived ability to diagnose, communicate with families about, treat/manage, and facilitate follow-up care. Of the 80% of residents that reported proficiency using screening tools for ASD, 68% answered that they had no/low confidence in distinguishing ASD from other delays, and 56% reported no/low confidence in formally diagnosing ASD. Of those residents who reported career plans in primary care, 92% indicated that further training and education about ASD is important/very important to their careers with 93% indicating that they moderately/very strongly feel that ASD concerns should fall within their scope of practice. For the residents in their last year of residency, 80% believed ASD concerns should fall within their scope of practice (regardless of career plans), but only 25% reported moderate/high levels of confidence in distinguishing ASD from other delays, and only 45% reported moderate/high levels of confidence in diagnosing ASD.

Conclusions: Pediatricians are the central figures within the medical home, which is increasingly functioning as the entry point for developmental and behavioral health intervention. In this capacity, enriching pediatric resident education through expanded training and experience in ASD detection and management will likely yield enhanced perceptions of care for providers and families alike.

289 **217.289** Predictors of Improved Adaptive Skills in Children with Autism Spectrum Disorder

R. Aishworiya[1] *and E. Law*[1,2], *(1)Paediatrics, National University Health System, Singapore, Singapore, (2)National University of SIngapore, Singapore, Singapore*

Background:

Although different modalities and intensity of early intervention services for Autism Spectrum Disorder (ASD) have been well studied, research on other modifiable variables prior to early intervention is limited. In Singapore, regular, long-term early intervention is provided for children with suspected ASD and other developmental disabilities from ages 0 to 7.

Objectives:

The aim of this study was to identify specific modifiable factors prior to early intervention and socioeconomic (SES) factors that are predictors of better outcome in children with ASD.

Methods:

Consecutive patients with ASD aged 5-year, 0-month to 7-year, 11-month were recruited from a tertiary developmental program in Singapore from August 2016 to July 2018. ASD diagnosis required a psychologist administered Autism Diagnostic Observation Schedule (ADOS) and an Autism Diagnostic Interview- Revised (ADI-R) with consistent clinical history and behavioural observations. The consent rate was 86.3% (N=199). Exclusion criteria were 1. Vision or hearing loss; 2. Significant neurological co-morbidity (cerebral palsy, epilepsy); and 3. Children with genetic syndromes. Parents of these children provided information on demographics, SES indicators and early intervention details (such as wait time and intensity).

The primary outcome was the Vineland Adaptive Behaviour Scales (VABS) Adaptive Behaviour Composite (ABC) score completed by a psychologist. Descriptive statistics were used to analyse family SES and early intervention factors. Using adaptive skills as the outcome, linear regression models were applied to determine significant correlates; specifically on variables prior to early intervention.

Results:

The sample consisted of 84.0% males, with a racial distribution similar to that of Singapore's general population (Chinese 67.7%, Malay 18.7% and Indians 4.5%). Mean age of the subjects was 6 years and 3 months (74.4 months, SD 13.1). Mean age at ASD diagnosis was 3 years and 5 months (41.4 months, SD 9.3). Mean VABS ABC standard score (mean 100, SD 15) was 77.8 (SD 15.9). Mean wait time for regular early intervention was 6.3 months (SD 3.0) and mean intensity of early intervention was 8.1 hours/week (SD 4.1). Linear regression showed that wait time for early intervention services was a strong predictor of the VABS ABC score after controlling for other child and parent variables (β=-1.14, p=0.03). Significant covariates also included maternal education (β= 5.39, p=0.04) and total score on the ADOS (β=-1.93, p=0.01).

Conclusions:

Wait time for early intervention services is a modifiable risk factor that can predict outcomes in children with ASD. When planning for early intervention services for these children, factors that reduce wait time should be a priority. Children from families with lower maternal education are at risk for poorer outcomes; hence ensuring an appropriate intervention plan for these children is of crucial importance.

290 **217.290** Revisiting a "WAIT and SEE" Mindset to Improve Early Intervention Referrals

E. Kaiser[1], *J. L. Stapel-Wax*[2], *N. M. Edwards*[3] *and K. Guerra*[1], *(1)Marcus Autism Center, Atlanta, GA, (2)Emory University School of Medicine, Atl, GA, (3)Interdisciplinary and Inclusive Education, Rowan University, Glassboro, NJ*

Background:

Advances in early screening and diagnosis make it feasible for experienced clinicians trained on validated tools to diagnose ASD by 18-24 months of age (Guthrie, Swineford, Nottke, & Wetherby, 2013). In spite of this, the median age for Autism Spectrum Disorder (ASD) diagnosis in the US is 4-5 years (Baio et al 2018), far beyond the window of opportunity for early intervention (EI).

There is often a delay between suspecting concerns and receiving services (Harrison & Roush, 1996). Many believe children will outgrow concerns (Wall et al., 2005). Building on the literature, a quasi-experimental design is used for an IRB-approved study of Primary Care Providers' (PCP) and parents' views on a ***'wait and see'*** mindset.

Objectives:

To determine whether and why some families and PCPs decide to wait before referring children with signs of delay for EI services and to gather suggestions for how to increase the willingness of PCPs and families to refer early.

Methods:

Parents of children with autism, some receiving EI, were sent an online survey and asked to participate in a phone interview. PCPs affiliated with a pediatric organization in a metro area were sent an online survey to complete.

Questions focused on: extent to which PCPs and families are using a 'wait and see' approach for developmental concerns; knowledge of and attitude towards EI/Part C

Results:

Family survey

- Completed by 13 of 50 families (26% response rate); additional surveys will be collected until April 2019
- 6 families consenting to a phone interview will complete a standardized qualitative interview by April 2019
- 10 of 13 had concerns about delay prior to age 2
- 11 of 13 relied on their PCP to make the referral
- Most believed their child would outgrow the problem

Primary Care Provider survey

Completed by 72 of 210 providers (34.30% response rate)

PCPs' views on '***Wait and See***':

- Families more likely to have this mindset (n = 40; 55.60%)
- Both tend to equally have this mindset (n = 18; 25.00%)
- PCPs more likely to have this mindset (n = 7; 9.70%)
- Neither have this mindset (n = 7; 9.70%)

PCPs admitting to personally taking this view:

- I have used 'wait and evaluate further' (n = 41; 56.90%)
- I have taken a 'wait and see' approach (n = 19; 26.40%)
- I have not been in this situation (n = 8; 11.10%)
- 1 BLANK; 3 who marked both 'wait and see' and 'wait and evaluate further'

Conclusions:

Family responses indicated that they might have sought a referral earlier if they had a better understanding of the signs of autism or developmental delay and that early intervention could help their child gain important skills. Families stated that they wished they had been aware of services that were available for their child/family.

PCP responses indicated a need for more training during residency and practice in early recognition of signs of autism, along with more time for

developmental screening.

291 **217.291** The Child Can't Chew: Another Reason for Selective Eating

***S. Asquith**, Carolina Speech & Language Center, Inc., Summerville, SC*

Background: Sally Asquith, MS, CCC-SLP, is the owner/executive director of Carolina Speech & Language Center near Charleston, SC. She has extensive experience with Pediatric Feeding Disorders, has been accepted for Board Certification in Swallowing/Swallowing Disorders, and is on the Executive Council of the International Association of Pediatric Feeding and Swallowing Disorders. In the course of treating children with ASD who were highly selective eaters, avoidant, and neophobic, the role of arrested oral-motor skills became a clear aspect of the feeding disorder. Reliance on soft, non-resistant foods is a typical hallmark upon intake. Children remain fixed on these foods due to a number of factors such as habit, neophobia, "sticky attention" with packaging, AND failure to advance the necessary mechanics to lateralize and crush age-appropriate foods. This poster aims to raise awareness of this issue, commonly overlooked by physicians, other professionals, and parents.
Objectives:

- Review current literature pertinent to the role of oral-motor development to the diagnosis and treatment of PFD in autism, as seminal textbooks (J Arvedson & L Brodsky; SE Morris; J Sheppard) advise.
- Complete a 5-year retrospective chart review of ASD patients with PFD in an outpatient clinic.
- Assess the incidence of poor oral-motor skills as an “unsung villain” and key variable in dx and tx of PFD in ASD.

Methods:

- Literature review
- Review all intake evaluations in a 5-year period
    - Code for oral-motor/chewing skills age-equivalent
    - Code for absence or presence/type of aversive reaction

Results:

- While there is an abundance of studies exploring behavior management of PFD and selective eating in autism, and there are also numerous studies on poor chewing/poor oral-motor in the neurotypical adult population, studies are minimal at best in examining the role of mechanics and ability to manage age-appropriate foods safely in pediatrics.
- 80% of pts with autism and PFD in chart review had significant oral-motor deficits, regardless of age.
- 60% of cases were also positive for aversive reactions

Conclusions:

Functional mechanical deficits are a key aspect of PFD in autism, across ages, and should be a basic consideration when diagnosing and treating selective eating.

292 **217.292** The Impacts of Sensory Processing Function and Emotional and Behavioral Problems on Self-Care Performance in Children with Autistic Spectrum Disorder

***C. T. Lin**, S. Y. Shen and C. Y. Huang, I-Shou University, Kaohsiung, Taiwan*

Background:
Self-care performance is increasing important to preschool children with autistic spectrum disorder (ASD) as they grow up. Participating in self-care activities facilitates children's cognitive and motor developments. Moreover, being independent in self-care performance archives children’s sense of accomplishment and self-confidence, and decreases caregiver’s caring burden and lowers parenting stress. Children with ASD often have sensory processing dysfunction and emotional and behavioral problems which might affect children’s performance in self-care. However, a lack of studies has investigated the impacts of these two critical child factors on self-care performance.

Objectives:

This study aimed to investigate the impacts of sensory processing function and emotional and behavioral problems on self-care performance in 3-6 year-old preschool children with ASD.

Methods:

The Item bank of computerized adaptive test (CAT) for measuring self-care performance (the CAT-SC) was used to assess self-care performance. Social Responsiveness Scale™ (SRS™-2) was used to identify ASD severity levels. The short form of Sensory Profile (SSP) was used to assess sensory processing function. The Child Behavior Checklist (CBCL) was used to assess emotional and behavioral problems. The multiple regression model was used to investigate the effects of sensory processing function as well as emotional and behavioral problems on self-care performance. The dependent variable was the total score of the item bank of the CAT-SC, and the independent variables included children’s age, sex, the total score of the SRS™-2, the total score of the SSP and the total score of the CBCL.

Results:

A sample of 33 preschool children with ASD was recruited in the study (mean age= 4.84, SD= 1.14), with 28 boys (84.8%) and 5 girls(15.2%). Most of the children had severe ASD (n=16, 48.5%). The stepwise multiple regression model revealed that children’s age (standardized β=0.71) and emotional and behavioral problems (standardized β=-0.44) were significantly related to children’s self-care performance (p<.01). That is, the older children had better self-care performance. On the other hand, children with more emotional and behavioral problems had poorer self-care performance.

Conclusions:

Among five critical child factors, only children's age and emotional and behavioral problems significantly related to self-care performance, which could serve as intervention guide for clinicians. Moreover, ASD severity levels and sensory processing function had no significant associations with self-care performance. This may be because of insufficient sample size of our study, which my need further research to investigate the associations between sensory processing function and self-care performance.

Poster Session
218 - Service Delivery/Systems of Care
5:30 PM - 7:00 PM - Room: 710

Health Care Utilization Patterns of Adults with Autism Spectrum Disorder in a Safety-Net Hospital

ABSTRACT WITHDRAWN

Background: Autism Spectrum Disorder (ASD) has become increasingly prevalent with the most recent CDC data stating that 1 in 59 children aged 8 years have been diagnosed with ASD (Baio, 2018). Despite the increasing prevalence of autism, there are few published studies analyzing healthcare utilization patterns in adults with autism. Based on data from Kaiser Permanente, Zerbo et al. compared healthcare utilization and costs among adults with ASD, adults with ADHD, and adults with neither condition (Zerbo et al 2018), and found that the utilization and costs of healthcare services among adults with ASD are higher than adults with ADHD or adults with neither ADHD nor ASD (Zerbo et al 2018). We aimed to better understand the utilization patterns for adults with autism in a safety-net hospital.
Objectives:

This study aims to identify the utilization patterns of different healthcare services among adults with ASD at Boston Medical Center (BMC).

Methods: The study population was retrieved from the clinical data warehouse of Boston Medical Center (BMC), which contained BMC patient data only. Adults 23 years of age and up at the time of any medical encounter were eligible for inclusion. Patients flagged with autism codes ICD-9 ([ICD-9 299.0] Autistic disorder; [ICD-9 299.1] Childhood disintegrative disorder; [ICD-9 299.8] Asperger's disorder; [ICD-9 299.9] Pervasive developmental disorder) and ICD-10 codes ([ICD-10 F84] Pervasive developmental disorder; [ICD-10 F84.0] Autistic disorder; [ICD-10 F84.2] Rett's syndrome; [ICD-10 F84.3] Other childhood disintegrative disorder; [ICD-10 F84.5] Asperger's disorder; [ICD-10 F84.8] Other pervasive developmental disorders; [ICD-10 F84.9] Unspecified pervasive developmental disorder) in the past ten years on either the problem list or the encounter were extracted from the database, and their encounters at BMC during 2017 were further retrieved as the sample data. The study included 304 adult patients, who made a total of 1,953 visits to BMC in 2017.

Results:

Of the 304 adult patients, 73 patients visited BMC once, and 64 patients visited twice in 2017. 62 adult patients had 10 or more encounters at BMC, and 2 had over 60 encounters. The total 1,953 encounters were broken down into four different visit types: outpatient (86%), inpatient (2%), emergency (10%) and other (2%). "Other" includes: observation, pre-admit, pre-clinic, recurring, and same day care visits. In addition, we identified the top 5 most frequently visited departments by number of encounters as follows: Psychiatric Clinic (227), Adult Emergency Department (180), Primary Care (152), Social Service Office (118), and Family Medicine (110).

Conclusions:

The average number of encounters per patient is 6.4, and 20% of the adult patients had 10 or more encounters in 2017. The most frequently visited departments were Psychiatry Clinic, Adult Emergency Department, and Primary Care. This information is helpful in informing efforts aimed at better supporting adults with ASD.

293 **218.293** Exploration of a Community-Based Early Intervention for Diverse Children with Autism

***J. B. Plavnick**, M. Y. S. Bak, A. D. Duenas and S. M. Avendano, Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI*

Background: Despite the efficacy of early intensive behavioral intervention (EIBI) for children with autism spectrum disorders (ASD), little is known about the feasibility of implementing EIBI services for a broad and diverse community. The present paper describes and explores a model of EIBI that was designed with community dissemination as a primary objective. The Michigan State University Early Learning Institute (ELI) is a community-based EIBI model that provides comprehensive programming for low-income children with ASD and their families. Although affiliated with a university, the ELI is a stand-alone collective of EIBI centers that serves children with ASD within existing early childhood centers (e.g., preschools) near their home communities. The ELI started with a single center serving eight children within an inclusive learning environment, where children with ASD could interact with typically developing peers at a very young age. The ELI quickly expanded services in a manner that maintained the intensive and inclusive qualities of the original program. There are currently three MSU ELI sites in mid-Michigan with XX children served over 3.5 years. The ELI is a unique EIBI program in that it emphasizes services for low-income children and families, is built into communities, maintains consistent services, and emphasizes inclusive therapeutic services in preparation for public school.
Objectives: This exploratory study describes the feasibility of implementing an inclusive EIBI program within community settings, primarily for low-income children with ASD. The specific objectives were to assess the likelihood of low-income families to enroll children in the program, evaluate adherence to treatment by calculating utilization over one year, and compare preliminary outcomes to those observed in prior EIBI literature.

Methods: Observational methods were used to assess the utilization of the ELI program among low-income families. A single group pre-test post-test design was used to assess for changes among children with ASD enrolled in the ELI following one year across several outcome measures including: the *Mullen Scales of Early Learning*, the *Vineland Adaptive Behavior Scales*, the *Social Responsiveness Scale – 2nd Edition*, and language samples.

Results: There were 31 spaces available for families to enroll their children at the ELI during the study period. Low income children were enrolled into 22 of the 31 spaces. Total utilization among low income children was a mean of 85% (range, 80% to 94%). A dependent samples t-test will be

used to test for change on outcome measures.

Conclusions: Preliminary data suggest the ELI has potential as a model for delivering EIBI to low-income children with ASD in community settings. Utilization among low-income families was substantially higher than levels observed in prior research, suggesting the ELI model may be accessible to diverse families. Children demonstrated gains on standardized measures, though these gains were less than those observed in highly controlled research studies. Implications of utilization and outcomes will be presented.

294 **218.294** Improving Access for Autism Diagnosis in Toddlers from a Multi-Cultural and Underserved Community

R. Choueiri[1], *M. Ravi*[2] *and W. Robsky*[2], *(1)University of Massachusetts Memorial Children's Medical Center, North Worcester, MA, (2)UMass Children's Hospital, Worcester, MA*

Background: Toddlers from families in underserved and low socioeconomic areas have difficulties accessing Autism Spectrum Disorders (ASD) diagnostic evaluations and treatment services in a timely manner. This can lead to sub-optimal outcomes. Furthermore, language and cultural barriers add to further delays.

Objectives: To improve access to autism diagnostic and treatment services in an underserved and multicultural community in Massachusetts (Worcester), while integrating a new level two screening test, the Rapid Interactive Screening Test for Autism in Toddlers (RITA-T) was introduced in an Early Intervention (EI) program. Current wait time for an autism evaluation in those below the age of three years old is 3-5 months.

Methods:

The RITA-T consists of nine interactive activities that evaluate developmental constructs delayed in toddlers with risk of autism. The RITA-T takes approximately ten minutes to administer. The language and commands integrated in the test are simple and do not require an advanced knowledge of the English language for comprehension. Four Early Intervention (EI) providers from the largest EI program in Worcester, THOM EI, were trained on the RITA-T. They administered the test to those who either had a positive Modified Checklist for Autism in Toddlers, Revised (MCHAT-R) or behavior concerns for ASD. Following screening, the toddler and his/her family were referred for further comprehensive testing by a diagnostic team in a tertiary care center. Those provided with an ASD diagnosis were referred to Applied Behavioral Analysis (ABA) services. Opportunities for follow up were offered for all.

Results: A total of 81 toddlers (78% male) were evaluated. Of the 81 toddlers evaluated, 58% were white, 20% were Hispanic, 15% were African-American, and 7.4% were Asian. The average age at screening was 27.4 months and the average time elapsed between RITA-T and final diagnosis was 42 days for children diagnosed with ASD, down from 3-5 months wait time. Referrals doubled to the local ABA provider, and age at referral decreased from 30 to 28 months.

Conclusions: The RITA-T is a useful Level 2 autism screening test that improves access for diagnosis and treatment for those in multicultural and underserved communities. Decreased wait times and expedited referrals to services improves outcome. Generalization of this model to other EI programs is underway in MA.

295 **218.295** Improving Access to Rural Mental Health Services Specific to Autism Spectrum Disorder

A. V. Dahiya-Singh[1], *L. Ingram*[1], *A. J. Gatto*[1], *J. Albright*[1], *L. Jensen*[1], *L. A. Ruble*[2] *and A. Scarpa*[1], *(1)Virginia Polytechnic Institute & State University, Blacksburg, VA, (2)University of Kentucky, Lexington, KY*

Background: Autism Spectrum Disorder (ASD) is a developmental disorder comprised of deficits in social communication and the presence of restricted interests and repetitive behaviors (APA, 2013). It is estimated to impact 1 in 59 children in the U.S. (Baio et al., 2018), affecting the individual's developmental trajectory in communication, social competence, and adaptive behavior. Early identification and intervention can improve outcomes for children with ASD (National Research Council, 2001), but access to such services is not equal across all demographic groups. Rural communities face significant challenges regarding the availability and adequacy of services for children with ASD due to various barriers. Specifically, the Appalachian Region is highly underserved as seen through numerous indicators such as higher mortality rates, higher number of unhealthy days, higher rates of obesity, and higher poverty rates.

Objectives: The current study aimed to identify barriers and strengths of rural communities in Southwest Virginia through mixed-methods analysis.

Methods: Quantitative and qualitative data were collected from questionnaires and focus groups, respectively, completed by caregivers and service providers. Six focus groups were conducted (3 with caregivers and 3 with providers) from the Mount Rogers Community Services Board catchment area, in Galax city, Smyth county, and Wythe county of Virginia. Caregivers included parents and grandparents of children with ASD aged 5-21 years. Providers included professionals who provided treatment/supports for children with ASD.

Total participants consisted of 15 caregivers and 33 providers. Caregivers reported on barriers related to accessing ASD services, as well as types of services that they perceived were important but lacked. Providers reported on their barriers with providing services, difficulties of their clients accessing ASD services, and the types of services that they perceived were important but lacked availability.

Results: Quantitative findings indicated that caregivers had difficulties accessing ASD services due to *few providers available* (66.7%), *few providers with ASD knowledge or training available* (66.7%), *geographic isolation* (40%), and *affordability* (40%). Additionally, providers reported that they had difficulty providing ASD services due to *lack of resources* (48.5%) and *lack of ASD knowledge* (39.4%). Qualitative findings indicated that this region lacks 1) sufficient resources for ASD diagnosis and treatment, and therefore more providers are needed, especially with specific training in ASD, 2) sufficient information, educational, and training resources, and therefore caregivers need additional education related to autism and what it entails, 3) sufficient personal support resources for caregivers, and therefore caregivers struggle with child behavior and mental health (social skills, communication, aggression, anxiety, trauma), and 4) coordination among medical providers, providers in public schools, and other community providers.

Conclusions: Overall, the region's needs related to the diagnostic services and treatments of ASD are multi-faceted, and the needs of availability, access, and affordability must be addressed.

296 **218.296** Improving Initial Age of ASD Diagnosis for Children from Culturally and Linguistically Diverse Communities: Asking the

Parents

P. Chaxiong[1], *A. Shipchandler*[1] *and J. A. Hall-Lande*[2], *(1)Educational Psychology, University of Minnesota, Minneapolis, MN, (2)UCEDD, University of MN, Minneapolis, MN*

Background:
The average age of a diagnosis of autism spectrum disorder (ASD) for children in the U.S is still after four, despite ability to reliably diagnose at two (Baio et al., 2018). For children from underserved, culturally and linguistically diverse (CLD) communities, this delay to diagnosis can be substantially greater (e.g., Shattuck et al., 2009; CDC, 2018). One CLD community in the U.S. with limited representation in ASD research is the Hmong community, a growing and underserved Southeast-Asian refugee group with a population size of approximately 300,000. As access to early and intensive intervention covered through insurance often requires a clinical diagnosis of ASD, delayed diagnosis can also mean delayed intervention.

Objectives:

The importance of early intervention warrants efforts to identify potential strategies for supporting CLD parents in obtaining an earlier diagnosis of ASD for their child. To identify potential strategies, we conducted a survey study examining Caucasian and Hmong caregiver experiences with the diagnostic process.

Methods:

Our survey examined (a) parent-reported barriers and facilitators to obtaining a diagnosis of ASD, (b) parent perceptions/knowledge of ASD identification, and (c) sources parents access for information on ASD (e.g., scientific article, blog, Facebook). The survey was previously conducted with a sample of predominantly Caucasian parents of individuals with ASD from a university research registry (n = 121; 91% Caucasain). A second sample is being conducted with Hmong parents of individuals with ASD.

Results:

Results from our first sample indicate that dismissal of parent concerns from healthcare professionals, long waitlists for evaluations, and dismissal of parent concerns from friends/family were the most frequently parent-reported barriers to obtaining a diagnosis of ASD for their child. Conversely, doing research, having knowledge of appropriate development, and recognizing the importance of an identification were the most frequently parent-reported facilitators. Additionally, parents reported turning most frequently to the internet, other parents of children with ASD, healthcare professionals, and books for information on ASD. We predict group differences between Caucasian and Hmong caregivers will exist across all outcome variables. Findings from a previously conducted systematic literature review, examining what parents report were barriers and facilitators to obtaining a diagnosis of ASD for their child, will supplement survey results and also be discussed.

Conclusions:

The results from this study will inform key strategies for supporting CLD parents, particularly Hmong parents, in obtaining a diagnosis of ASD for their child earlier. Specifically, identifying barriers and facilitators identifies problem areas that can be targeted, as well as supportive factors that can be enhanced to support parents in obtaining a diagnosis of ASD. Additionally, an understanding of parent perceptions of identification and the sources parents access for information on ASD indicates the messages regarding identification that need to be reinforced as well as the effective methods for delivering those messages. This work also contributes to the limited literature base on ASD in CLD communities.

297 **218.297** Increasing Universal ASD Screening in Primary Care: A Pragmatic Trial with a Six-Month Follow-up

W. L. Stone[1], *K. J. Steinman*[2], *L. V. Ibanez*[3] *and J. P. Espinosa*[4], *(1)Psychology, University of Washington, Seattle, WA, (2)Neurology, University of Washington and Seattle Children's Hospital, Seattle, WA, (3)UW READi Lab, Seattle, WA, (4)UW READi Lab, University of Washington, Seattle, WA*

Background:
Although the American Academy of Pediatrics recommends universal use of ASD-specific screening at 18 and 24 months, compliance by primary care providers (PCPs) is limited by time constraints and lack of confidence regarding ASD care. The Modified Checklist for Autism in Toddlers–Revised with Follow-up (M-CHAT-R/F, Robins, 2014), is a well-validated screener comprising a 20-item parent checklist and a follow-up interview for positive initial screens, designed to reduce false positives. However, limited time allotments for well-child visits often result in the omission of the follow-up interview, leading to potential over-diagnosis.

Objectives:

To examine the effectiveness of an intervention for community-based PCPs designed to: (1) increase the use of the M-CHAT-R/F at 18 month well-child visits, and (2) increase PCP self-efficacy regarding clinical care for toddlers with possible ASD.

Methods:

Sample. 61 PCPs from 10 practices in 4 counties across Washington State were enrolled. PCPs had a mean age of 45.2 years and mean of 13.7 years in practice. The majority were MDs (72.9%) and female (75.0%).

Procedures. A stepped wedge design was used to randomly assign each county to the timing of intervention. Survey data were collected at baseline (T1) and 6-months post-intervention (T2). The intervention comprised a 2-hour, interactive training workshop conducted in each PCP practice. Workshops focused on the introduction of a novel online version of the M-CHAT-R/F, along with information about the importance of universal ASD screening at 18 months, early behavioral features of ASD, strategies for talking to families about ASD concerns, and local ASD resources.

Online M-CHAT-R/F. An online version of the M-CHAT-R/F was developed using REDCap (Research Electronic Data Capture; Harris et al., 2009) and is accessed via tablets. This version triggers the follow-up questions when appropriate, and provides automated scoring. Medical staff access the results via the final screen, which is color-coded to indicate pass/fail status, and can log-in directly to REDCap to review the specific items failed.

Measures. Self-report measures of screening practices and self-efficacy regarding ASD care were collected at T1 and T2. At T2 only, feasibility and acceptability of the online M-CHAT-R/F were measured with items adapted from the User Rating Profile (URP; Chafouleas et al., 2011), and objective data on 18-month screening rates were obtained from the REDCap database.

Results:

The percent of PCPs using the M-CHAT-R/F follow-up interview increased from 37% to 91%. Significant increases in PCPs' self-efficacy in caring for

young children with ASD were found (see Table 1). Provider ratings indicated high levels of feasibility and acceptability for the online M-CHAT-R/F (Table 2). At T2, 7 of the 10 practices were using the online M-CHAT-R/F routinely at 18-month visits.

Conclusions:

This brief community-based intervention was effective for increasing PCPs' use of universal ASD screening at a 6-month follow-up period. PCPs rated the online M-CHAT-R/F as feasible and acceptable. While automation of the M-CHAT-R/F scoring removed a common barrier to screening (i.e., lack of time), improvements in provider self-efficacy regarding ASD care may have also contributed to increased rates of universal screening.

298 **218.298** Living without Adequate Community Mental Health Support: The Experiences of Parents of Post-Secondary Students with Autism and Co-Occuring Mental Health Challenges

A. Cozma[1] *and A. McCrimmon*[2]*, (1)University of Calgary, Calgary, AB, Canada, (2)Werklund School of Education, University of Calgary, Calgary, AB, Canada*

Background: Young adulthood marks an especially demanding transitional period for young adults with Autism Spectrum Disorder (ASD) pursuing post-secondary education, and their families. Young adults with ASD experience higher rates of co-occuring mental health challenges compared to others with or without developmental disorders. In addition, policies typically mandate individuals with ASD to make the transition from child to adult health services at age 18, involving a disruption of daily routines and contact with familiar health care providers. Studies show that adult-based community mental health agencies are not typically inclusive of individuals with ASD. It is imperative to gain a better understanding of the experiences of young adults with ASD and co-occuring mental health challenges that may or may not be mental health service users to delineate the characteristics and effectiveness of mental health care delivery systems versus other kinds of informal mental health supports.
Objectives: To conduct a qualitative inquiry of parental perspectives on the experiences of post-secondary students with ASD and co-occuring mental health challenges while accessing or trying to access mental health services and/or informal mental health supports in one Canadian province.

Methods: The experimental methodology involves conducting semi-structured interviews with parents or legal guardians of young adults (age 18 to 30 years, currently enrolled in post-secondary education) with ASD and co-occuring mental health challenges. Data collected through interviews include feedback on formal or informal diagnoses of ASD and mental health challenges, including psychiatric disorders, and experiences during assessments and while accessing or trying to access support for mental health needs in relation to perceived attainment of post-secondary academic success.

Results: Results show that young adults with ASD and co-occuring mental health challenges experienced barriers while accessing or trying to access support for mental health needs. The majority of parents/legal guardians identified unsuccessful attempts to access mental health supports for their children. The most common barrier to accessing mental health supports was found to be restrictive intake criteria. The most common barrier to receiving effective mental health supports was found to be lack of perceived clinicial confidence to care for the population of young adults with ASD and co-occuring mental health challenges.

Conclusions: Knowledge disseminated from this study contributes a qualitative inquiry on the characteristics and effectiveness of mental health care delivery systems versus other kinds of informal mental health supports. The study findings support the view that young adults with ASD and co-occuring mental health challenges are a population for whom optimal supports may not currently be accessible, and they highlight the need for a broader environmental scan of supports that can further inform critical gaps in funding and policies.

299 **218.299** Long-Term Follow-up of Primary Care Workforce Training in ASD Identification in Young Children: Does Advanced Training Facilitate Sustainable Practice Change?

A. Swanson[1]*, J. F. Hine*[2]*, M. Colon*[3]*, A. S. Weitlauf*[4]*, Q. Humberd*[5] *and Z. Warren*[2]*, (1)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Developmental Medicine, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)Independent Consultant, Nashville, TN*

Background:
The increased prevalence of autism spectrum disorder (ASD) and documented benefits of early intensive intervention have created a need for flexible systems for determining eligibility for autism-specific services.

Objectives:

This study evaluated the long-term effectiveness of a training program designed to enhance autism spectrum disorder identification and diagnosis within community pediatrics and related early intervention system settings across several state systems of care over a 10-year training period.

Methods:

An electronic survey was distributed to 493 participants who completed STAT-MD training designed to teach early identification of ASD for pediatric health care providers and facilitate within practice diagnosis and management of young children with ASD. Participants were asked to detail aspects of practice both prior to and after receiving STAT-MD training, including barriers associated with practice changes.

Results:

At the time of submission, results came from:

- 120 practitioners
- Variety of settings (private practice, academic medicine, military instillations)
- 11 US states, plus Japan, Trinidad and Tobago, and Puerto Rico
- Following training, practitioners reported an increase in comfort level for discussing potential ASD diagnosis with families of children below 36 months of age ($p<0.01$) and reported an increase in their ratings of appropriateness to provide ASD diagnosis prior to or without referral to tertiary centers ($p<0.01$). Surveys will continued to be collected until early 2019 to account for practitioners in 2018 training workshops, to include a new program in rural areas of Alaska.

Conclusions:

A percentage of pediatric providers participating in the advanced training reported significant changes in screening and consultation practices following training, with some demonstrating long-term practice change. Such collaborative training methods that allow ASD identification within broader community pediatric settings may help translate enhanced screening initiatives into more effective and efficient diagnosis and treatment. At the same time, potent barriers towards completion of such training and long-term practice change are evident:

- Low response rate to survey itself
- Varied post training practice settings
- Administrative and billing barriers to assessment

These barriers may require novel engagement strategies for sustainable long-term practice change.

300 **218.300** Mixed Methods Study of Early Learning Institute (ELI) Program Implementation across Three Early Intervention Sites

A. Sridhar[1], *T. E. Bustos*[1] *and A. Drahota*[2], *(1)Michigan State University, East Lansing, MI, (2)Psychology Department, Michigan State University, East Lansing, MI*

Background:

Autism spectrum disorder (ASD)—affecting 1.5% of the population—is a pervasive, lifelong neuro-developmental disorder characterized by impaired social communication and repetitive behavior and/or restricted interests. Early behavioral intervention (EBI) is an effective treatment for reducing ASD symptoms and improving development for young children at-risk or diagnosed with ASD. EBI is typically delivered through community-based agencies; yet, little is known about the quality of these services. One method for ensuring quality community-based EBI is to translate efficacious curriculum into community settings that provide services to young children with ASD. The Early Learning Institute (ELI), based on the work of Maurice, Green, & Luce (1996) and Lovaas (2003), provides evidence-based curriculum to children with ASD between the ages of 2-5 years. This study aimed to better understand the implementation process of ELI delivered at three community agencies in the mid-Michigan region in order to facilitate its dissemination and implementation into broader community-based early intervention settings.

Objectives:

- Assess implementation processes and implementation outcomes (appropriateness, feasibility, acceptability, and utility) related to ELI utilization.
- Explore staff perspectives on use of implementation strategies and processes.
- Collect data on facilitators and barriers of the ELI program curriculum, training, and implementation process to facilitate further dissemination to community-based organizations.

Methods:

A sequential explanatory (QUAN --> qual) mixed methods design was utilized to evaluate facilitators and barriers to ELI implementation within and between three sites.

QUAN Phase: Twenty-five providers (4 directors/administrators, 2 BCBA and 19 behavioral technicians (BT)), completed a web-based quantitative survey, including the Acceptability of Intervention Measure, Intervention Appropriateness Measure, Feasibility of Intervention Measure, Implementation and Sustainment Strategies Survey and the Leadership Culture, Staff Culture, Leadership Behavior and Measurement Subscales of the Organization Readiness to Change Assessment (ORCA) to gather data on the organizational characteristics, provider characteristics, implementation strategy use, and implementation factors hypothesized to influence initial and sustained use of ELI.

Qual Phase: A sub-sample of 13 providers (1 administrator, 1 BCBA, 11 BT's) participated in a semi-structured interview that was developed based on QUAN findings. The interview focused specifically on facilitators and barriers to delivering ELI in community-based settings. Qualitative coding, utilizing grounded theory, has been completed using an iterative coding, comparison and consensus methodology.

Results:

ANOVAs indicated no significant differences in ratings of acceptability, appropriateness, or feasibility by site or provider role. However, significant differences in ORCA ratings were found between provider roles in leadership culture, [$F(2, 24)=6.36$, $p=0.007$], with lower ratings from BT's ($M=3.08$, $SD=0.89$) as compared with directors/administrators ($M=4.19$, $SD=0.55$) and BCBA's ($M=4.88$, $SD=0.18$). No other significant differences on the ORCA were found between sites or provider roles.

Quantitative and qualitative data are being integrated through the use of joint display, and will be presented at the conference.

Conclusions:

Findings will highlight key facilitators and barriers to successful implementation of ELI that may be able to generalize to other community-based early intervention settings for children with ASD, helping to inform the process of adoption, implementation and sustainment within these contexts and facilitate broader uptake of ELI into community-based settings.

301 **218.301** National and State-Level Trends in Adult Supplemental Security Income (SSI) Awardees with ASD: 2005-2017

K. Anderson[1], *A. Roux*[2], *J. Rast*[3], *P. Shattuck*[3], *J. Hemmeter*[4], *J. Baller*[5] *and D. Wittenburg*[5], *(1)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)Office of Research, Demonstration, and Employment Support, Social Security Administration, Baltimore, MD, (5)Mathematica Policy Research, Princeton, NJ*

Background: The Supplemental Security Income (SSI) program, a nationwide cash assistance program, is an important yet understudied source of financial support for adults with Autism Spectrum Disorder (ASD). Prior research found a 327% national increase in the number of working-age SSI recipients with ASD between 2005 and 2015. However, the possibility of changes in the characteristics of this population has not yet been explored.

Objectives: Specific research questions included: 1) How has the number and proportion of SSI awardees with ASD changed over time and how do these changes vary by age?; 2) How has the demographic composition of awardees with ASD changed, and how do these changes compare to awardees other disabilities?; and 3) How did the number of SSI awardees with ASD vary across states and over time?

Methods: We used Social Security Administration (SSA) program data from 2005 to 2017 to examine national- and state-level changes in the composition of new SSI awardees (ages 18-64) with respect to gender, age, SSI history and the relative size of the ASD group. We also present data on the population of awardees with intellectual disability (ID) and other mental disorders (OMD) to help contextualize our findings.

Results: The number of awards for ASD increased dramatically, rising from 3,384 in 2005 to 12,096 in 2017 (a total increase of 257.4%). In contrast, the number of ID awards declined by 54.9% and OMD awards declined by 48.9% decrease. Nine out of every 10 ASD awards were given to young adults, ages 18 to 25 years. This figure has been relatively stable across the years, suggesting that growth in transition age young adults is not driving overall increases in the population of ASD awardees. The composition of awardees with ASD did not significantly change between 2005 and 2017 with respect to age, gender and SSI history. However, there were significant between-group differences in awardee characteristics. Overall, awardees with ASD were younger (mean age 20.9 years) and had a higher percentage of males (81.0%) compared to awardees with ID and OMD. All states reported increases in both the number and proportion of ASD awards between 2005 and 2017. However, the degree of growth varied considerably across states (ranging from a low of 2.1% in New Mexico to a high of 12.7% in New Jersey—a difference of 10.6%). By comparison, the number of ID and OMD awards declined in every state. Our findings also indicate a general increase in state heterogeneity in the prevalence of ASD awards. Across all 50 states and Washington D.C., the average proportion of ASD awards increased by 8.0 percentage points between 2005 and 2017, and the standard deviation increased by 251.1%. In contrast, state-level variability declined in the ID and OMD groups between 2005 and 2017.

Conclusions:

Findings from this study underscore the need to consider geographic and age differences in SSI participation among individuals with ASD and identify how these differences relate to variation in economic outcomes across states and disability groups.

302 **218.302** Scholars of Human Expression: The Experiences of Autistic Performing Arts Professionals and Attitudes of Performing Arts Employers in the UK

E. Buckley[1], *E. Pellicano*[2] *and A. Remington*[3], *(1)UCL Centre for Research in Autism & Education, London, United Kingdom, (2)Macquarie University, Sydney, Australia, (3)UCL Centre for Research in Autism and Education, London, United Kingdom*

Background: Researchers and clinicians have long held that imagination is limited in autism. Yet it is increasingly recognised that creativity is an area of strength in many autistic people. Although creative practice such as the performing arts has not traditionally been thought of as an occupation in which autistic people would engage, our initial work in this area has revealed that there are people diagnosed as autistic and those with high levels of autistic traits working in this field. Further, autistic people and those with high levels of autistic traits reported wanting more employment support than non-autistic colleagues. We still need to establish, however, the nature of these support needs and the experiences of autistic adults in the performing arts.

Objectives: This research examined in-depth the employment experiences of autistic performing arts professionals and the attitudes and adjustments of performing arts employers who work with autistic people. We sought to better understand the challenges that autistic adults face in performing arts employment and the nature and extent of the support they require.

Methods: Semi-structured interviews were carried out with 18 UK-based autistic performing arts professionals (7 female, 9 male, 2 non-binary/other; mean age 33) and 19 UK-based performing arts employers (10 female, 9 male; mean age 44). Interviews with autistic professionals focused on their likes and dislikes concerning their workplaces, and if they had ever needed or would like support for their work. Employers were asked about their current knowledge of autism, whether they had any experience working with autistic people, and if they knew how or where to find support for either an autistic employee or themselves if needed.

Results: Interviews were recorded, transcribed verbatim, and analysed using thematic analysis. Autistic performing arts professionals described facing challenges in the workplace. These centred on anxiety, colleagues' misconceptions, and feeling obliged to network despite finding high levels of socialisation stressful. Professionals also spoke about how autistic traits benefitted their work: being able to focus on tasks for a long time and work in precise detail, and how being autistic enabled them to approach their work from a unique perspective. A few autistic professionals had access to support, but the majority felt that there was not enough, if any, support available and highlighted many ways in which they could be better supported. Performing arts employers varied in their experiences of working with autistic people, but they consistently identified that every autistic person has different needs and requires individualised support. Many employers had limited knowledge about autism-specific support or relied on other professionals to provide it. They indicated a willingness to learn more, but were concerned that there was little time for training.

Conclusions: The results paint a picture of meaningful contributions of autistic people within the performing arts yet a number of challenges with which to contend. Crucially, these findings allow us to understand the current unmet support needs of autistic performing arts professionals, and make best-practice recommendations in this area. Future research should develop and evaluate employment-based support for these professionals.

303 **218.303** Practices Surrounding Autism over-Diagnosis and Under-Diagnosis: Results from a National Healthcare Provider Survey

A. Azim[1], *K. Zuckerman*[2], *C. R. Candelaria-Rosario*[3], *C. Ponce*[4], *R. Phelps*[5] *and R. Rdesinski*[6], *(1)Oregon Health and Science University, Portland, OR, (2)Division of General Pediatrics, Oregon Health & Science University, Portland, OR, (3)Biology, Pontificia Universidad de Puerto Rico, Arecibo, Puerto Rico, (4)Department of Pediatrics, Oregon Health and Science University, Portland, OR, (5)Child Development and Rehabilitation Center, Institute on Development and Disabilities, Oregon Health and Science University, Portland, OR, (6)Department of Family Medicine, Oregon Health and Science University, Portland, OR*

Background: The prevalence of autism spectrum disorder (ASD) increased tenfold in the last 40 years, prompting concern about autism misdiagnosis and over-diagnosis. Few studies have assessed ASD over- or under-diagnosis, or the practice of assigning ASD diagnoses for children not meeting Diagnostic Statistical Manual (DSM) criteria.

Objectives: To measure rates of healthcare provider-reported over- and under-diagnosis of ASD in a national sample of U.S. ASD providers. To assess providers' reasons for over- and/or under-diagnosis of ASD.

Methods: A mixed-mode (email/mail) survey was sent to all members of the Society of Developmental and Behavioral Pediatrics (SDBP) who indicated a clinical interest in ASD, performed at least 5 ASD evaluations in the prior year, and who were currently practicing in the US. Each respondent used a Likert-type scale to indicate: (1) whether he/she thought autism was over-diagnosed, under-diagnosed, or diagnosed at the appropriate rate; (2) whether he/she had personally diagnosed a child with ASD when the child did not meet DSM criteria ("over-diagnosis"); (3) whether other providers in his/her area over-diagnose children with ASD; (4) whether he/she had personally not diagnosed a child with ASD when the child did meet DSM criteria ("under-diagnosis"). Reasons for under- and over-diagnosis of ASD were assessed. Descriptive statistics were used to assess rates of self-reported over- and under- diagnosis, and multivariable logistic regression was used to assess variability in responses according to respondent gender, years in practice, and US region

Results: 217/347 (63%) of eligible providers completed the survey. Overall, 48% of providers thought that autism was diagnosed at an appropriate rate. More providers thought ASD was over diagnosed (32%) than underdiagnosed (19%; p = 0.008). 8.8% of providers self-reported over-diagnosing ASD at least sometimes; however, 58% reported that other providers over-diagnosed ASD at least sometimes. Commonly-cited reasons for ASD over-diagnosis included: assisting in access to school services (46.1%) and assisting in access to medical services through health insurance (47.6%). Male providers were significantly more likely to self-report over-diagnosing ASD compared to female providers (16.7% versus 5.7%; Adjusted Odds Ratio 3.24 [95% Confidence Interval 1.17-9.02]). 7.8% of providers self-reported under-diagnosing ASD. There were no significant provider demographic associations with under-diagnosis. Commonly-cited reasons for under-diagnosis included: parents really did not desire the diagnosis (35.4%) and parents weren't ready to hear the diagnosis (43.4%).

Conclusions: Relatively few U.S. providers self-report over-diagnosis of ASD; however, they report that this practice pattern is widespread among local colleagues. Under-diagnosis was less common. Study results suggest that ASD over- and under-diagnosis may be occurring in a meaningful portion of reported ASD cases in the US. Over-diagnosis may present an effort on behalf of ASD providers to facilitate access to limited services.

304 **218.304** Predictors of Changes in Daily Activity in Transition-Aged Youth with Autism

J. Lai[1], *Y. Lunsky*[2] *and J. A. Weiss*[3], *(1)McGill University, Montreal, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, ON, Canada, (3)Psychology, York University, Toronto, ON, Canada*

Background: Transitioning into adulthood is fraught with challenges for young adults on the autism spectrum. The fragmented nature of social and community services does not promote a seamless transition from youth to the adult service sectors. At the same time, community involvement of these transition-age youth (TAY), whether it be continued schooling, employment, or vocational training, plays a crucial role for meaningful outcomes later in adult life. Therefore, a greater understanding of the facilitators of continued community involvement during this period is warranted.

Objectives: In this study, we aim to identify the association between clinical need and service receipt with the stability of community involvement in young adults with autism that are transitioning into the adult service sector.

Methods: Caregiver survey data was taken from the baseline Canadian Autism Spectrum Disorders Alliance (CASDA) National Autism Needs Assessment Survey in 2014. Caregivers (n=330) that elected to be contacted again were sent the same set of questions in 2017 about sociodemographic factors, clinical need, service receipt and their typical weekday activity in the last four months. Three cohorts based on age were defined: (1) youth who were between 14-17 years of age at time 2; n=227) and thus not transitioning in the 3 year period, (2) transition-age youth (TAY), who were under 18 years of age at time 1 but aged into the adulthood at time 2, ending up between 18-21 years of age at time 2; n=48) and (3) adults who were past transition age at both time periods (25-29 y.o. at time 2, n=55). We compared patterns and predictors of having a typical structured daily activity during the week (either school, employment or volunteer activity) of the TAY group with both the younger and older cohorts who had not experienced this transition during the same time period. We then identified the service use and clinical need predictors of losing a typical structured daily activity over this transition period.

Results: Aside from age, the three groups did not differ with respect to rurality, gender, caregiver education level or income. Those in the adult group were less likely to live with family (67%) compared to the TAY (85%) and youth groups (97%). At time 2, only 1.3% of youth had no structured activity, compared to 17% of the TAY group, and 45% of the adult group. Of those that had a structured daily activity at time 1, a significantly larger portion of the TAY group lost a daily activity at time 2 (29.2%), compared to youth (6.2%) and adults (14.5%). We will present further data on what predicted losing services in the TAY group.

Conclusions: This research highlights that those transitioning to adulthood are a greatest risk of losing structured daily activities, and that once in adulthood (at least for individuals 25-29 years of age), many continue to struggle to obtain meaningful postsecondary engagement. These results can help guide the design of youth and transition age programs that will impact adult outcomes.

305 **218.305** Prevalence and Correlates of Significant Spoken Language Delay in Preschool-Aged Children Seen at an Autism Clinic

J. L. Feuerstein[1,2], *L. Kalb*[1,3], *E. F. Dillon*[1,2], *G. F. Azad*[1,3] *and R. Landa*[1,4], *(1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Psychiatry & Behavioral Sciences, The Johns Hopkins University School of Medicine, Baltimore, MD, (3)Department of Mental Health, Johns Hopkins University, Baltimore, MD, (4)Department of Psychiatry & Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Understanding profiles of preschool-aged children with significant spoken language delay at time of autism evaluation is important to identify service delivery needs. Currently, little is known about the prevalence of spoken language delay in this population, and which factors may distinguish children with and without phrase speech.

Objectives: Data from children (ages 36 – 59 months) seen for evaluation at an interdisciplinary, urban autism clinic were examined to: (a) ascertain the prevalence of spoken language delay, defined as parent-reported lack of phrase speech by age 36 months, and (b) examine demographic, educational, and diagnostic differences among children with and without phrase speech.

Methods: Data were collected from a pre-appointment background and history questionnaire completed by caregivers. Parent-reported phrase-speech was validated by clinician-administration of ADOS Module1. Chi-square and *t*-tests were calculated to compare bivariate differences

between groups.

Results: *Demographic & Speech Profiles.* Children (*N*=691) were mean age 47.41 months (*SD*=7.15); 80.46% were male; 62.37% were using phrase speech; 37.63% were not. Children without phrase speech were younger (*M*=45.12, *SD*=7.30 months) than children with phrase speech (*M*=48.80, *SD*=6.70 months), $t_{(689)}$=-6.76, *p*<0.001. No sex differences were found between groups (*p*=.66). Clinicians administered an ADOS Module1 for 90.85% of children whose parents reported no phrase speech (ADOS data available for *n*=468 children). A lower proportion of phrase speech was observed among children who were Other/Multi-Racial (57.81%) or Black/African American (46.26%), when compared to Caucasians (71.94%), $X^2_{(2, N=674)}$=31.01, p<0.001. Families with private insurance had a greater proportion of children with phrase speech (66.88%) compared to families with Medicaid (50.98%), $X^2_{(2, N=691)}$=17.05, *p*<0.001.

Early Intervention Status. The proportion of parents with concerns about their children's language development was higher in children without (91.89%) versus with (61.88%) phrase speech, $X^2_{(1, N=292)}$=31.66, *p*<0.001.The proportion of children who received early intervention services was greater in children without (45.10%) than those with (32.08%) phrase speech, $X^2_{(1, N=679)}$=11.59, *p*=.001. Among children without phrase speech for whom data were available (*N*=257), 24.12% were not receiving speech therapy and, among a smaller subset with available data (*N*=111), only 9.01% had access to a speech generating device.

Diagnostic Status. The proportion of children identified as having autism based on clinical impression was higher in children without phrase speech (85.24%) compared to those with phrase speech (67.18%), $X^2_{(2, N=427)}$=16.55, *p*<0.001. Mean ADOS Comparison Score among children without phrase speech (*n*=160) was higher (*M*=6.44, *SD*=2.70) than the mean Comparison Score (*M*=5.47, *SD*=2.77) among children with phrase speech (*n*=302), $t_{(460)}$=3.59, *p*<.001.

Conclusions: More than one-third of children seen for autism evaluation were not using phrase speech by age three years, and, despite parent concerns, more than half had not received early intervention. Children most at risk for spoken language delay were Non-White and those who received medical assistance. Results suggest the need for pediatrician and clinician training on the importance of early speech-language intervention for young children with autism and significant spoken language delay. Such training should include education on the value and efficacy of augmentative and alternative communication for this population with autism.

306 **218.306** Primary Care Medical Home Designed for Young Adults with Autism Reduces Emergency Department Utilization

B. N. Hand[1], *E. K. Schmidt*[1], *A. Hess*[2] *and C. Hanks*[3], *(1)Health and Rehabilitation Sciences, The Ohio State University, Columbus, OH, (2)The Ohio State University/CAST, Hilliard, OH, (3)The Ohio State Unviersity Wexner Medical Center, Hilliard, OH*

Background: Young adults with autism spectrum disorder (ASD) are at elevated risk for frequent utilization of the emergency department (ED) due to psychiatric conditions, medical comorbidities, and poor continuity of primary care. The Center for Autism Services and Transition (CAST) at The Ohio State University Wexner Medical Center (OSUWMC) was co-designed with adults with ASD, caregivers, and providers to reduce barriers to primary care access and develop strategies for improving patient self-management of healthcare conditions. Figure 1 provides a schematic representation of the CAST program. The overall goal of this program is to help adults with ASD build the skills they need to ultimately be able to obtain medical care anywhere from providers beyond CAST.

Objectives: The objective of this study was to examine the association between number of years in the CAST program and ED utilization.

Methods: A retrospective longitudinal design was used to analyze administrative records from CAST patients with at least one ED visit that occurred between the years 2015-2018 (n=61 patients). A majority of patients were male (79%), white (80%), and had a co-occurring intellectual disability (66%). The median age of patients in 2015 was 21 years (interquartile range [IQR]: 17, 25). During the study period, these CAST patients visited any OSUWMC ED a total of 311 times with a median number of 3 visits per patient (IQR: 2, 7). Repeated measures negative binomial regression was used to examine the association between number of years in the CAST program and number of ED visits per year for: 1) any reason, and 2) non-emergent conditions. Covariates included sex, race, age, co-occurring intellectual disability, and the number of OSUWMC ED visits in the year prior to CAST program enrollment.

Results: Enrollment in the CAST program for two (IRR=0.7 95% CI=0.5-0.9), three (IRR=0.6, 95% CI=0.4-0.9), or four years (IRR=0.4, 95% CI=0.2-0.8) was associated with a significantly lower rate of ED visits, relative to the first year of enrollment. Additionally, enrollment in the CAST program for two (IRR=0.5, 95% CI=0.3-0.9) or three (IRR=0.3, 95% CI=0.1-0.7) years was significantly associated with fewer ED visits for non-emergent conditions, relative to the first year of enrollment. Four years of enrollment was also associated with a decrease in non-emergent ED visits (IRR=0.2), although this finding did not reach statistical significance (95% CI=0.1-1.0). Figure 2 provides a graphical demonstration of how the risk for any ED visit and non-emergent ED visits decreases as years in the CAST program increases.

Conclusions: Two years of enrollment in the CAST program was associated with 30% reduction in the number of annual ED visits and a 50% reduction in risk of visits for non-emergent conditions. Additionally, program participation continued to reduce ED utilization after three and four years of enrollment. These findings suggest that the CAST program is effective at improving access to quality primary care, thereby reducing over-reliance on ED services. Further work is needed to examine the impact of this program on other aspects of healthcare utilization.

307 **218.307** Provider Perspectives on Parent-Provider Communication about ASD Detection: Implications for Applying Shared-Decision Making

P. Carpentier[1], *L. V. Ibanez*[1], *E. Posner*[1], *L. Frederick*[2], *J. Locke*[2] *and W. L. Stone*[3], *(1)UW READi Lab, Seattle, WA, (2)Speech & Hearing Sciences, University of Washington, Seattle, WA, (3)Psychology, University of Washington, Seattle, WA*

Background: Challenges in parent-provider communications about early ASD concerns may contribute to delays for detecting ASD and accessing specialized treatment. During the detection process, parents have indicated that providers did not offer sufficient support and advice about the nature of ASD (Osborne & Reed, 2008). Community early intervention (EI) providers have reported a lack of comfort and uncertainty about their role in discussing concerns with parents, including what specific information should be conveyed (Cameron & Muskett, 2014). Both parents and providers seem to agree that greater sharing of information is needed to support the families during the diagnostic process (Keenan et al., 2010). Further research on EI providers' perspectives about discussing early ASD concerns and referrals may yield key insights on ways to improve parent-provider communication and apply shared-decision making, which promotes a balanced partnership that capitalizes on both parents' and providers' unique expertise, values, and beliefs.

Objectives: Identify the common issues/facilitators that arise when providers communicate with families in their caseload about ASD concerns and make decisions about appropriate next steps/referrals.

Methods: Three 90-minute focus groups were conducted by a facilitator using a semi-structured guide and audio recorded for transcription and coding. Participants included 25 EI providers from 3 EI agencies in a large urban setting. Grounded Theory (Corbin & Strauss, 2014) was used to identify the themes in reviewing the transcripts. All transcripts were coded by two independent coders and inter-coder reliability was met for all themes.

Results: A total of 5 major themes emerged**.** As part of their unique role in working with children with ASD/ASD concerns, providers indicated that they felt responsible for introducing/discussing concerns about ASD and providing parents education on the topic. When bringing up ASD concerns to parents, providers indicated that they attempted to introduce the concerns gradually over time/sessions in order to gently assess parent readiness and avoid parents rejecting their concerns and discontinuing EI services. With regards to parents' acceptance and follow through for referrals, providers indicated that influential factors included parent awareness and motivation and child symptomatology (and its severity). When working with families from different cultural backgrounds, providers indicated that they confronted additional barriers including parents' perceptions of stigma and ASD and miscommunication due to language differences. When making recommendations for ways to improve parent-provider communication, providers indicated the need to use strategies that: (1) lead to a better understanding of parents' perspectives; (2) provide parents clarity about the next steps (i.e., waitlists and types of services); and (3) include simple, visual materials that can be used with all parents, including those from different cultural backgrounds and/or with possible literacy issues.

Conclusions: Findings re-affirmed that providers face various challenges when communicating with parents about ASD concerns and referrals. Given the challenges and recommendations that emerged, using shared-decision making may lead to considerable improvements in parent-provider communication because its primary components/strategies involve: (1) seeking and supporting parent participation, (2) exploring/explaining the next steps clearly, (3) assessing parents' beliefs and values, and (4) reaching and monitoring a decision.

308 **218.308** Provider Use of Evidence-Based Practices for Students with Autism in School-Age Transition Periods

B. Bronstein[1], *E. McGhee Hassrick*[2], *C. Friedman*[2], *S. Iadarola*[3], *A. R. Fitzgerald*[4], *J. Chiappe*[5], *L. Hauptman*[6], *A. C. Stahmer*[7], *D. S. Mandell*[8] *and C. Kasari*[6], *(1)University of Pennsylvania, Philadelphia, PA, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)University of Rochester Medical Center, Rochester, NY, (4)Department of Psychiatry and Behavioral Health, UC Davis Mind Institute, Sacramento, CA, (5)University of California Los Angeles, Los Angeles, CA, (6)University of California, Los Angeles, Los Angeles, CA, (7)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (8)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Several treatment methods found to be effective for teaching children with autism have been identified as evidence-based practices (EBP) (Odom et al., 2010; Wong et al., 2014), and training teachers on EBPs is best way for schools to provide effective education students with ASD. Teachers may struggle with implementation of EBPs as interventions are time intensive, costly, and require significant training to implement with high fidelity (Lopata et al. 2012). Teachers face additional barriers including decreased financial resources, lack of curriculum materials, high staff turnover, poor training, and resource challenges for children whose families live at or below the poverty line (Mandell et al., 2013; Pellechia et al., 2015). Educators often use practices with limited evidence-base for individuals with ASD (Stahmer, Collings & Palinkas, 2005). Teachers may particularly disengage in EBP use during stressful times, such as times of transition. Research highlights the importance of successful transitions as well as the difficulties for children considered at risk (Pears et al., 2015). Given the associated difficulties of transition, teachers report a lack of training opportunities, knowledge and attention to students' individual needs as well as school coordination gaps during transition (Nuske et al. 2018).

Objectives: To identify reported use of evidence-based strategies and interventions for under-resourced individuals with ASD in public school classrooms during times of transition.

Methods: Under-resourced students with ASD attending public schools enrolled in the study prior to transition to primary or secondary school. School personnel providing interventions were interviewed before and after transition and asked to report strategies used in pre and post transition classrooms to meet student goals. Authors first coded reported intervention data using codes that identified general types of interventions (n=10 intervention types), derived from a list of common practice intervention types, then authors coded the reported intervention data using EBP codes, derived from Wong et al. (2014) (n=15 EBP). For both coding rounds, coders reached IRR at 0.8 and 20% of data were double coded. For double coded data, discrepant codes were coded using consensus. SPSS was used to report descriptive statistics for the coded data.

Results: Pre and post-transition school personnel (n=30) reported implementing 198 total strategies for students (n=7). Overall, 35% of strategies were identified as not EBP. The most frequently used EBPs reported were prompting (13%) and visual supports (13%). The least frequently reported EBPs were technology aided instruction and intervention (1%), discrete trial training (1%) and PECS (1%) (Table 1). Of the strategies identified as not EBP (n=70), instructional interventions (14), self-regulation (11) and consequence-based interventions (10) were most frequent. The percent frequency of reported EBP interventions was similar pre-transition (64%) and post-transition (65%).

Conclusions: Educators reported implementing various strategies for students with ASD during transitions. Although many strategies were reported, there is variability in the evidence-base of the strategies being used. Understanding these patterns highlights current gaps in EBP and may inform needed adjustments to implementation and dissemination efforts in real-world settings.

309 **218.309** Risk Factors for Emergency Department Utilization Among Adolescents with Autism Spectrum Disorder

G. Liu[1], *A. Pearl*[2], *S. L. Brown*[3], *L. Kong*[1], *D. Ba*[4], *D. Leslie*[5] *and M. Murray*[2], *(1)Penn State College of Medicine, Hershey, PA, (2)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA, (3)Psychiatry, Penn State University College of Medicine, Hershey, PA, (4)Penn State University College of Medicine, Hershey, PA, (5)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA*

Background: During recent years children and adolescents with autism spectrum disorder (ASD) have be increasing their ED utilization at a higher rate compared to those without ASD. Investigation is needed into the risk factors for elevated ED utilization among adolescents diagnosed with ASD who are more vulnerable for psychiatric emergencies.

Objectives: This study mined a large, national healthcare claims database to examine healthcare utilization history of adolescents with ASD to

identify risk factors for elevated ED utilization.

Methods: Using MarketScan® between 2005 and 2014, we designed a retrospective, longitudinal study to determine the risk factors associated with the ED utilization among adolescents (aged 12-21) with ASD. We identified ASD subjects as those with at least two separate diagnoses of ASD (ICD-9 codes 299.0x and 299.8x) through the entire study period. The ED utilization was summarized at the individual level on a yearly basis, with an index date of the first ED visit during that year. For a calendar year without ED visit, the index date is set to be July 1st. Risk factors include mental health comorbidity; psychotropic medications; prior visit(s) to a psychiatrist, prior ED visit and demographic characteristics (age, sex, etc.).

Results: Our study cohort consists of 63,886 ASD patients with 181,686 person-year observations. Multivariable logistic regression analysis examining the independent effect of each factor on ED utilization found a statistically significant sex-by-age interaction effect on ED utilization (p=0.03). While female adolescents with ASD generally were more likely to visit ED than males, sex effect was significant in early and late adolescence (age 12-14: adjusted Odd Ratio 1.24; 95% confidence Interval [1.13-1.37]); 18-21: 1.26 [1.14-1.39]), but not in middle adolescence (15-17: 1.08 [0.98-1.19]). Meanwhile, the longitudinal effect of age depends on sex. For females, the odds of ED visit significantly increased when patients entered late stage adolescence (age bracket 12-21 vs. 12-14: 1.24 [1.08, 1.42], age bracket 15-17 vs. 12-14: 0.99 [0.88-1.11]). In contrast, the odds of ED visits among males increased monotonically over time. In addition, having internalizing (e.g. digression) type of mental health comorbidity alone or concurrently having externalizing comorbidity (e.g. adhd) increased the odds of ED visits significantly (concurrent: 1.27 [1.19-1.37]; internalizing only: 1.17 [1.08-1.28]; Reference: neither); but not with the externalizing comorbidity alone (1.02 [0.94, 1.10]). Clearly prescriptions of more categories of psychotropic drugs were associated with higher ED risk. Even prescriptions of just two categories of these medications significantly elevated the odds of ED visit (1.20 [1.12-1.30]). Finally, a prior ED visits was strongly associated with recurrent ED visits (9.55; [8.93-10.23]).

Conclusions: This study has reaffirmed previous work documenting higher ED utilization by adolescent females than males among adolescents with ASD. Concurrent externalizing and internalizing psychiatric comorbidities as well as internalizing conditions alone correlate to higher ED utilization. Illness severity as demonstrated by psychiatric referral and use of two or more classes of psychotropic medications also appear to mark vulnerability for ED utilization. Previous ED visits appear to correlate most strongly for future ED utilization.

310 **218.310** Polypharmacy of Psychotropic Medications May Increase the Risk of Emergency Department Visits Among Adolescents with Autism Spectrum Disorder

G. Liu[1], *L. Kong*[1], *D. Ba*[2], *D. Leslie*[3] *and M. Murray*[4], *(1)Penn State College of Medicine, Hershey, PA, (2)Penn State University College of Medicine, Hershey, PA, (3)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA, (4)Department of Psychiatry/Division of Autism Services, Penn State Hershey/Penn State College of Medicine, Hershey, PA*

Background: Studies have documented high prevalence rates of using psychotropic medications to manage comorbid mental health concerns in children and adolescents with ASD, particularly older children and adolescents with ASD. It is not uncommon for physicians to prescribe multiple psychotropic medications both within and across drug classes. However, little is known about the effectiveness of polypharmacy to minimize high level service, utilization such as the Emergency Department (ED) for behavior and/or mental health crises.
Objectives: This study used a large, national healthcare claims database of a privately insured population in the US to investigate the association between prescription patterns of psychotropic medications and the incidence of ED visits for adolescents with ASD.

Methods: Using the MarketScan® database between 2005 and 2014, we designed a retrospective, longitudinal study to describe the prescription patterns of psychotropic medications (MEDs) among adolescents (aged 12-21) with ASD and potential ED visits. We identified ASD subjects as those with at least two separate diagnoses of ASD (ICD 9 codes 299.0x and 299.8x) through the entire study period. ED utilization was summarized at the individual level on a yearly basis, with the index date defined as the first ED visit date in a calendar year, or set to be July 1st for a year without ED visits. Prescribed psychotropic MEDs within 3 months prior to the index date were documented. Other potential risk factors/confounders considered include mental health comorbidity and demographic characteristics (age, sex, etc.). Descriptive analyses and multivariable regressions were performed to estimate the effect of psychotropic MED prescriptions on ED utilization.

Results: Our study cohort consists of 63,886 ASD patients with 181,686 person-year observations (Table 1). Annually, 57.7% had ≥1 psychotropic MEDs prescribed within 3 months prior to the index date and 17.6% concurrently had ≥3 different psychotropic medications concurrently prescribed. More older adolescents were prescribed ≥ 3 MEDs (age 18-21: 19.0% ; age 15-17: 18.8%; age 12-14: 15.7%). 35% of adolescents with ASD having both internalizing and externalizing mental health comorbidities were prescribed ≥3 psychotropic MEDs, followed by those with internalizing comorbidities only (27.8%), those with externalizing comorbidities only (20.3%), and those with neither (8.9%). Multivariable logistic regression analysis showed that (Table 2), while there was essentially no increase in ED risk with prescribing 1 or 2 psychotropic MEDs, prescription of ≥3 MEDs was associated with a significantly increased risk of ED visits (adjusted Odds Ratio [95% Confidence Interval]=1.26 [1.14, 1.38] vs. 2 MEDs).

Conclusions: In this privately insured population, nearly 60% of adolescents with ASD had at least one prescribed psychotropic medication annually and 17.6% had 3 or more concurrent psychotropic MEDs within 3 months of ED utilization. Our study has provided evidence that psychotropic polypharmacy is associated with elevated risk of ED visits among adolescents with ASD. Further studies are warranted to examine whether this is reflective of greater symptom severity, more complex presentations, suboptimal medication management, under-utilization of other treatments, or some other factor(s).

311 **218.311** Service Experiences of Autistic Women with Anorexia Nervosa

C. Babb[1], *J. Brede*[2], *C. R. Jones*[3], *L. Serpell*[2], *W. Mandy*[4] *and J. R. Fox*[5], *(1)Cardiff Univeristy, Cardiff, United Kingdom, (2)Research Department of Clinical, Educational and Health Psychology, University College London, London, United Kingdom, (3)Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom, (4)University College London, London, United Kingdom of Great Britain and Northern Ireland, (5)South Wales Doctorate in Clinical Psychology, Cardiff Univeristy, Cardiff, United Kingdom*

Background:
Anorexia Nervosa (AN) is a severe, restrictive eating disorder (ED). 20-30% of women in treatment for AN are on the autism spectrum (Huke et al., 2013). Moreover, autistic women receiving treatment for AN have poorer outcomes compared to non-autistic women receiving the same treatment (Stewart et al., 2017; Wentz et al., 2009). There has been limited research investigating autistic women's experiences of ED services. This project is

part of the Study of Eating Disorders in Autistic Females (SEDAF).

Objectives:

To explore experiences of ED services from the perspectives of autistic women with experience of AN, the parents of autistic women, and professionals working in relevant services.

Methods:

Interviews covering ED service experiences were conducted with 15 autistic women with experience of AN (mean age 32 years, range 25-38), 15 parents, and 15 professionals working in ED and/or autism services. A collaborative approach to thematic analysis (Braun & Clarke, 2006) was used to identify themes for each of the three groups. Autistic women with experience of AN acted as advisors to the study. They helped develop the interview schedule and contributed to the data analysis and interpretation.

Results:

Preliminary analysis has focused on the interviews provided by the autistic women.

Service Engagement: Services were reported to lack understanding of autism. Autism-related social and sensory difficulties were often seen as a failure to engage with treatment and sometimes led to discharge. Not yet having a diagnosis of autism invariably led to autistic behaviours being misinterpreted.

Treatment Approaches: Common therapeutic approaches included cognitive behavioural therapy (CBT) and dialectic behaviour therapy (DBT). CBT was helpful for some autistic women, but many suggested the approach was too abstract and their difficulties in thinking flexibly held them back. DBT was seen as more helpful due to its focus on emotion regulation and practical skills. Participants generally favoured individual therapy, as they disliked speaking in front of others or had difficulty following and engaging in group conversation.

Service Improvements: Providing information before an inpatient admission was valued. Moreover, meetings with staff and a tour of the inpatient ward allowed autistic women to feel more prepared before being admitted. Individualised approaches and staff with an understanding of autism improved autistic women's engagement and their trust in services' ability to treat them.

Conclusions:

Autistic women reported being unable to fully benefit from the services they were offered, which is likely to impact on their well-being and treatment outcomes. This difficulty with engagement was primarily attributed to a lack of understanding of and adjustment for autism within services. However, the women provided insight into service and treatment approaches that could best meet their needs. This research may inform service adaptations to meet the needs of autistic individuals as well as the development of autism-specific interventions to treat AN.

312 **218.312** Service Use Classes Among School-Aged Children from the Autism Treatment Network Registry

O. Lindly[1], *J. Chan*[2], *S. E. Levy*[3], *R. A. Parker*[4] *and K. Kuhlthau*[2], *(1)General Academic Pediatrics, Massachusetts General Hospital, Boston, MA, (2)Massachusetts General Hospital, Boston, MA, (3)Division of Developmental and Behavioral Pediatrics, Center for Autism Research, Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, (4)Biostatistics, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Use of specific services may help to optimize health for children with autism spectrum disorder (ASD); yet, little is known about their service utilization patterns.

Objectives: We, therefore, aimed to (1) define service use groups and (2) determine associations of sociodemographic, developmental, behavioral, and health characteristics with service use groups among school-aged children with ASD.

Methods: We analyzed cross-sectional data on 1,378 children aged 6-18 years with an ASD diagnosis who were enrolled in the Autism Speaks Autism Treatment Network Registry, from years 2008-2015 across 18 sites in North America. We used data from the first follow-up visit (9-15 months post baseline) on 13 service use indicators spanning behavioral and medical therapies (e.g., behavioral interventions, psychotropic medications, special diets). Latent class analysis was used to identify groups of children with similar service use patterns. Bivariate and multivariable analysis was then used to determine associations of sociodemographic, developmental, behavioral, and health factors with services use groups.

Results: Latent class analysis placed school-aged children with ASD into 4 services use classes: limited services [LS] [12%], multimodal services [MS] [36%], predominantly educational and/or behavioral services [EBS] [43%], and predominantly special diets and/or natural products [SDNP] [9%] (Figure 1). Multivariable analysis results showed children in the LS class were significantly older and had significantly less severe ASD than those in the EBS class. Children in the MS class had significantly more externalizing behavior problems than those in the EBS class, and children in the SDNP class had significantly higher income and significantly poorer quality of life compared to those in the EBS class (Table 1).

Conclusions: Results suggest distinct service use groups exist among school-aged children with ASD following diagnosis and may be related to certain sociodemographic, developmental, behavioral, and health characteristics. Together, these findings may be used by health professionals to better support families in decision-making about service use for their child with ASD following diagnosis.

313 **218.313** Social Services Referrals and Child Protection Plans Involving Autistic Children and Children with Intellectual Disability in the United Kingdom

S. Griffiths[1], *M. Kovacs*[1], *C. Allison*[2] *and S. Baron-Cohen*[2], *(1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

Autistic individuals are at increased risk of victimisation by peers throughout the lifespan. It is less clear whether autistic children are also at increased risk of maltreatment by adults as children. There is good evidence that intellectual disability increases the risk for maltreatment. Additionally, some studies have found that autism increases a child's risk of ending up in the child protection system in some states in the USA, but this has not been investigated in the United Kingdom at a population level.

Objectives:

The current study aims to determine whether autism diagnosis and/or intellectual disability (ID) increase children's risk of being referred to social services and/or becoming the subject of a child protection plan (which are put in place if there is evidence of maltreatment) in the UK using population data.

Methods:

Data from the National Pupil Database (NPD), which includes information about all children in the state funded school system in the UK, was obtained from the Department of Education for the 2015-16 school year (N= 7,973,400). Unique Pupil Identification numbers were used to link school records and social service records that contain information on whether a child has been referred to social services, and whether they have received a child protection plan. Information on demographic factors (age, gender, ethnicity, home language and socioeconomic status) were also extracted from the NPD. Special educational needs diagnosis information was used to identify whether or not each child had autism and/or and ID. Logistic regression was used to determine the odds of being referred to social services and receiving a child protection plan depending on autism diagnosis and ID.

Results:

After adjustment for demographic variables and ID, autism significantly increased the odds of being referred to social services (odds ratio =2.83, 95% CI 2.78-2.89). Having ID also independently increased the odds of referral to social services (odds ratio =2.54, 95% CI 2.51-2.56). After adjustment for demographic variables and ID, there was no evidence that autism increased the odds of receiving a child protection plan (odds ratio = .919, 95% CI .859-.983). Conversely, ID significantly increased the odds of receiving child protection plans (odds ratio = 1.75, 95% CI 1.71-1.80).

Conclusions:

After adjusting for the effect of ID, autism does not increase the risk of receiving a child protection plan in the UK, indicating autism does not independently increase the risk of maltreatment by adults. However, children with ID (including a significant proportion of autistic children) are at a significantly increased risk of maltreatment. A limitation of this study is that it only includes cases of maltreatment that are identified by social services. Further work is needed to identify the impact maltreatment on autistic and non-autistic children with ID.

314 **218.314** The Autism Spectrum Ambassador Program: Enhancing a Novel Medical Student Run Program

***H. Patel**, A. Fairfull and C. Tierney-Aves, Penn State Hershey Medical Center, Hershey, PA*

Background: Recent studies have identified that children with Autism Spectrum Disorder (ASD) often face negative experiences when accessing healthcare. Triggers for these patients can include changes in routine and anxiety from interactions with new people and environments. The Autism Spectrum Ambassador Program (ASAP) aims to improve the healthcare experience for pediatric patients diagnosed with ASD and their families by providing the child and family with a medical student Ambassador to accompany them and facilitate accommodations on their behalf during a medical or surgical procedure at the Penn State Hershey Children's Hospital.

Objectives: This study aims to use a common quality improvement methodology (PDSA cycles) to improve recruitment and enrollment for our novel medical student run Ambassador program.

Methods: Program materials were created by study personnel to teach medical students about autism and the Ambassador Program. This program pairs ASAP-trained medical students with a family whose child is scheduled for an outpatient procedure and who may benefit from accommodations to improve cooperation and procedure tolerance. We realized over the first full year of implementation that the protocol to identify and recruit participants was not as effective as we had hoped. To identify potential barriers we used structured, open ended interviews with every member of the study team. A flowchart detailing the protocol steps was created and changes to the study protocol were made based on the feedback learned from interviews to maximize the program's success.

Results: In the 2 years after the program's inception, 23 patients were identified for enrollment. Ten participants were enrolled as controls. While 13 were enrolled into the intervention group, only 4 were assigned student Ambassadors. The remaining 9 did not complete the accomodation survey despite several reminders to do so. Figure 1 details the themes identified and potential solutions for each barrier as a result of the interviews conducted. Figure 2 depicts a flow chart which links each barrier (colored letter) with the step in the protocol that is affected. We decided to focus changes that would 1) increase the number of available Ambassadors, 2) better identify potential study participants, and 3) enhance the flexibility of the consenting process. Changes included 1) allowing student Ambassadors to create and distribute accommodation plans even if they themselves were not available to be at the child's procedure in person, 2) distributing study flyers to all clinic sites and re-educating the surgical sub-specialities about the program and 3) adding an option to consent potential recruits over the phone rather than only when they were in the hospital for a planned visit. While plans for protocol changes have been made, no data have yet to be collected.

Conclusions: While the ASAP program aims to improve the healthcare experience for pediatric patients diagnosed with ASD and their families, barriers exist that prevent the positive impact of this program to be fully realized. We hope that recent changes to the protocol informed by detailed interviews with study personnel will lead to improved outcomes for our patients with autism and their families.

315 **218.315** The Implementation of Reciprocal Imitation Training (RIT) with Toddlers in a Community-Based Setting

***L. V. Ibanez**[1] and W. L. Stone[2], (1)UW READi Lab, Seattle, WA, (2)Psychology, University of Washington, Seattle, WA*

Background: Numerous studies have indicated that early, ASD-specialized treatment leads to significant improvements in social, language, cognitive, and behavioral functioning for children with ASD. However, very few treatments have been adapted for use in community-based settings, where they may reach a broader segment of the population and remedy limited access. This study examines the implementation of Reciprocal Imitation Training (RIT)--an evidence-based, ASD-specialized treatment–by community Early Intervention (EI; IDEA Part C) providers serving toddlers from birth to 3 years.

Objectives: To examine: (1) the effectiveness of a system-level intervention (i.e., training workshop) for EI providers for increasing their self-efficacy when providing intervention to toddlers with possible ASD; (2) key implementation factors related to providers' use of RIT (i.e., adoption, acceptability, feasibility); and (3) providers' perceptions of RIT effectiveness for improving key outcomes.

Methods:

Sample.62 EI providers from 9 agencies in 4 counties across Washington State were enrolled. Providers had a mean age of 42.3 years and mean of

15.2 years in practice. The majority were speech-language pathologists (46.5%) or occupational therapists (23.3%) and female (93.8%).

Procedures. A stepped-wedge design was used to randomly assign counties to the timing of the system-level intervention. Survey data were collected at baseline (T1) and 6-months post-intervention (T2). The system-level intervention comprised a 1-day training workshop conducted for each agency, which focused on imitation impairments in ASD, the RIT cycle steps, parent coaching, and live demonstrations and practice.

RIT. RIT (Ingersoll, 2008) is a manualized ASD-specialized treatment that uses a naturalistic developmental behavioral approach (NDBI; Schreibman et al., 2015) to teach object and gesture imitation within a play-based context. RIT was chosen because of its strong evidence base (Ingersoll, 2010; 2012), ease of administration, flexibility, and focus on a core deficit area for ASD. Given its low intensity and playful nature, RIT is suitable for toddlers with delays in imitation and unlikely to have any negative consequences if used with toddlers who do not have ASD.

Measures. Self-report measures of practices and self-efficacy regarding ASD care were collected at T1 and T2. At T2, providers rated items about RIT feasibility and acceptability from the User Rating Profile (URP; Chafouleas et al., 2011) and about perceived RIT effectiveness.

Results: There were significant increases in providers' self-efficacy in identifying and discussing treatment goals with families of children with ASD, $p<.01$. At T2, provider ratings indicated high levels of feasibility and acceptability for RIT (Table 1). 48 providers (81%) reported using RIT with 349 children and coaching 277 parents. The majority of these providers indicated that they perceived RIT to improve key parent-child outcomes (Table 2).

Conclusions: These findings suggest that a relatively brief training workshop can increase EI providers' use of an evidence-based ASD treatment with their caseload and feel more efficacious in working with families of children with possible ASD. While additional research is needed to directly assess its effectiveness at improving parent-child outcomes, RIT may help families get an early start on accessing specialized treatment within an established infrastructure available across the U.S.

316 **218.316** The Penn State Hershey Children's Hospital Autism Spectrum Ambassador Program: A Novel Medical Student Run Advocacy Program

***A. Fairfull**, P. Dalal, D. Rovito and C. Tierney-Aves, Penn State Hershey Medical Center, Hershey, PA*

Background: Autism Spectrum Disorder (ASD) is one of the most common pediatric neurodevelopmental disorders in the U.S with prevalence of 1 in 45 children. The number of patients with ASD presenting for therapeutic or diagnostic procedures under sedation/anesthesia is increasing. These children face significant barriers interacting with the healthcare team and often have negative experiences. Recent literature shows that Autism care plans are effective in improving patient experience and outcomes; however, no study has evaluated the implementation of custom care plans with use of an adjunct medical student ambassador (MSA) model.
Objectives:

1. Describe a novel, student-run advocacy program for children with ASD undergoing medical procedures
2. Assess patient satisfaction with a customized Accommodation Plan (AP) implemented by the healthcare team and with having a MSA during the procedure
3. Analyze changes in career interests and ease of interaction with children with ASD for participating medical students

Methods: The Autism Spectrum Ambassador Program (ASAP) is a Penn State Children's Hospital initiative for training medical students to advocate for patients with ASD during a medical procedure under anesthesia. Following IRB approval and parental consent, a convenience sample of children with ASD were enrolled in the pilot project. Subjects were assigned to either the intervention or control arm based on availability of a MSA. Each child's guardian completed an Accommodation Survey prior to his/her procedure to identify unique accommodations to be implemented during the hospitalization. Then, an individualized AP was made based on Accommodation Survey responses and distributed to the child's healthcare team, regardless of whether a MSA would be present that day or not. Both parents and MSAs were requested to complete a Satisfaction Survey shortly after the procedure.

Results: A total of 23 children (13 intervention and 10 controls), ages 5-17 years and 78% male, were enrolled in this pilot program. Of those in the intervention group, 4 were paired with a MSA. 50% of controls completed the satisfaction survey compared to 31% of those in the intervention group. 75-80% of the participants felt that ASAP enhanced their patient experience when compared to a prior hospitalization. Importantly, MSAs did not have a negative effect on patient experience by patient report. MSAs appeared to enhance the staff's implementation of the APs (from 60% to 100% in our sample). There was a small shift in reported MSA career interest to Developmental Pediatrics after program completion. 100% of students reported both feeling more comfortable with this patient population and high satisfaction with the overall experience.

Conclusions: ASAP aims to improve the patient experience for pediatric patients diagnosed with ASD and for their families. Experiences with the program were overall positive, and the MSAs were well received. For MSAs, there was a small shift in career interest and an increased comfort level while interacting with special-needs children. The researchers anticipate that changes in the recruitment process is warranted to enhance participant enrollment and acknowledge the full value of the program.

317 **218.317** The Service Provider Perspective: "What Services Do I Need and Want?" Vs. the Thoughts of Service Providers.

***V. K. Korhonen**, Autism Foundation Finland, Helsinki, Finland*

Background:
Service providers aim to provide services that will benefit the service users. The service users often receive services they do not find useful, need, want or like. There are several reasons for the discrepancies ranging from not being heard, not finding the right professionals, to having bureaucratic reasons why the right kind of service is not funded for the individual. More importantly, and more often than not, the service provider may not know what is the best service they should provide.

Objectives:

The aim is to explore how service providers and services are found, what are the services that are found to be useful by the services users and which ones are not, why people drop out from services, and do professionals and individuals with ASC have the same answers to these questions.

Methods:

An online web survey and phone interview survey was conducted in Finland. Two entities were contacted: professionals who work with ASC and individuals with ASC. Individuals at the age 15 or above were targeted due to the national school curriculum after which services are provided by other organisations than schools.

Results:

The ongoing survey has reached by now 580 professionals and 152 individuals with ASC. In the poster we will present the survey participant demographics more thoroughly and the analyses of the survey data.

Conclusions:

The survey results will be discussed in relation to the way service providers should try to impact their service design to reach correct outcomes but also to have services that are found to be useful by the service user. We will also suggest that data should be used to alter the ways funding is placed on different services by municipalities and by the state in order to have the voices of the services users to be h

318 **218.318** Transition to Adult Healthcare for Teens and Young Adults with ASD

J. Harris[1], *L. Gorman*[2], *A. Doshi*[3], *S. K. Dickson*[4] *and S. Swope*[5], *(1)Children's Specialized Hospital, Mountainside, NJ, (2)Medical, Children's Specialized Hospital, Mountainside, NJ, (3)Autism, Children's Specialized Hospital, Mountainside, NJ, (4)Medical, Children's Specialized Hospital, Newark, NJ, (5)Medical, Children's Specialized Hospital, Hamilton, NJ*

Background: With increases in Autism Spectrum Disorder (ASD) prevalence, not only is the number of children diagnosed with ASD increasing, but the number of adolescents with ASD who are transitioning to adulthood is also rising. This results in a growing number of young adults with ASD transitioning from the pediatric to adult health care systems. Without a coordinated transition plan, pediatric providers often continue to provide care to young adults with ASD that is beyond the scope of their medical training. When adult providers are identified who are willing to assume the care of young adults with ASD, they often feel unprepared to address the unique needs of this population.
Objectives: Develop resources for pediatric and adult medical providers to facilitate transition to adult healthcare for teens and young adults with ASD.

Methods: A pediatric primary care practice that serves children with ASD and other special health needs as well as their typically developing siblings was identified. Staff, patients, and families were surveyed to determine baseline transition practices. Existing resources were identified. New resources for staff, patients, and families were created and implemented. Results from utilization of resources and technologies were accessed to identify improvements and barriers.

Results: Baseline data revealed much variability across staff and families regarding addressing transition. In addition to the need for improved consistency, topics needing greater attention were identified. These included financial and legal issues as well as vocational, educational and recreational options post high school. An evidence-based and replicable Patient Checklist, starting for patients at age 12 and continuing through ages 21+, was implemented to improve transition activities within the practice. The checklists included a formal transition policy, staff and family educational resources, a templated HEEADSSS -ASD assessment to aide providers in structuring a psychosocial interview with a young adult with ASD, a transition registry to create a working database of transitioning patients, and a comprehensive transition template imbedded into the practice EMR system to track completion of transition goals for individual patients. While designed for the transitioning patients of a pediatric practice, these same elements can guide an adult primary care practice in readying their practice to receive young adults with ASD.

Challenges in implementing the transition process included finding time within provider schedules to discuss transition-related issues with patients/families, changing existing practices and methodologies throughout the organization to help support the new transition model, and identifying adult providers with whom to collaborate regarding patients' ongoing care needs. Those families for whom the process was implemented reported better preparation for transition including greater access and knowledge of adult systems of care and more satisfaction with medical care from adult providers.

Conclusions: Transition from the pediatric to the adult healthcare systems presents unique challenges for people with ASD. To ensure a coordinated and seamless transition, the process must be clearly outlined and started early in adolescence, the adolescent and family must be an integral part of the transition process, and there must be collaboration and communication between the pediatric and adult care providers.

319 **218.319** Use of a Novel Care Model to Reduce Behavioral Crisis Emergency Room Visits and Inpatient Psychiatric Hospitalization Length of Stay

M. Lamy[1], *E. Pedapati*[1], *L. Wink*[1], *K. Dominick*[1], *R. Holden*[2], *R. Sorensen*[2], *R. Shaffer*[2], *C. Frye*[1], *L. Terhune*[1], *C. Norman*[1], *J. Imhoff*[1], *A. Duett*[1], *A. R. Dean*[1], *L. McClellan*[1], *W. Anthony*[1], *M. Warner*[1], *M. Sorter*[1] *and C. A. Erickson*[1], *(1)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: In patients with autism and other neurodevelopmental disorders, high patient acuity and limited outpatient care resources contribute to high emergency room (ER) visit rates while in crisis. This represents a significant burden to the healthcare system in terms of cost and potential for injury to the patient, family and medical staff.
Objectives: 1) To determine if enhanced outpatient care management was associated with reduced ER visit rates for behavioral reasons. 2) To determine if enhanced outpatient care management was associated with decreased length of stay.

Methods:

This chart review was approved by the Cincinnati Children's Hospital Medical Center IRB. High acuity patients within our neuropsychiatry continuum of care were enrolled in enhanced care management. All enrolled patients had a diagnosis of Autism Spectrum Disorder (ASD) or other neurodevelopmental disorder and a history of significant healthcare utilization for behavioral and/or medical reasons. All patients received 1) outpatient nurse care management including frequent phone calls to families and care coordination 2) mental health specialist support in the outpatient psychiatry clinic and 3) efforts to provide direct admission to inpatient psychiatry when possible in order to avoid an ER visit. Utilized chart review to gather data from the first 47 consecutive patients enrolled in our enhanced care management program. Data on ER visits for

behavioral health reasons and inpatient psychiatry hospitalizations was collected from patients for the year prior to enrollment in care management and at least one year post-enrollment.

Results:

Forty-seven patients with a mean age of 15.1 years (stdev 3.9) were included in this analysis. Enrollment in neuropsychiatry enhanced care management was associated with a statistically significant ($p<0.0001$) decrease in both the annual number of ER visits for behavioral reasons and the annual number of days admitted to the inpatient psychiatry unit. The average number of annual ER visits prior to enrolling in enhanced care management was 1.4 visits (range 1-8 visits, stdev 0.9). After enrollment in enhanced care management, the average number of annual ER visits was 0.5 visits (range 0-4 visits, stdev 0.6). Average annual length of inpatient stay pre-enrollment was 13.1 days (range 4-45 days, stdev 7.6), while the average annual length of inpatient stay post-enrollment was 5.6 days (range 0-22 days, stdev 4.9).

Conclusions:

Enrollment in the enhanced neuropsychiatry care management program was associated with a statistically significant decrease in annual ER visits, with an estimated annual cost savings of $103,400 ($2,200 per patient per year). The average annual length of inpatient stay was also significantly decreased with an estimated annual cost savings of $514,650 ($10,950 per patient per year). Future work will include assessing for changes in patient and family quality of life, and assessing injury reduction in the ER and the inpatient psychiatry unit.

320 **218.320** Usual Care Intervention Practices for Youth with Co-Occurring Autism Spectrum Disorder and Intellectual Disability

M. L. Braconnier[1], *L. Moskowitz*[2], *C. M. Kerns*[3], *A. Drahota*[4], *L. Soorya*[5], *A. Wainer*[5], *A. Chacko*[6] *and M. D. Lerner*[7], *(1)Psychology, St. John's University, Queens, NY, (2)Psychology, St John's University, Queens, NY, (3)University of British Columbia, Vancouver, BC, Canada, (4)Psychology Department, Michigan State University, East Lansing, MI, (5)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (6)New York University, New York, NY, (7)Psychology, Stony Brook University, Stony Brook, NY*

Background: Approximately 31% of children with Autism Spectrum Disorder (ASD) have a comorbid intellectual disability (ID) (Baio et al., 2018). As co-occurring ID has been found to predict poor prognosis in ASD (Matson & Shoemaker, 2009), there is a need to better understand the usual care of core social and associated psychiatric symptoms in this population.

Objectives: Understanding usual care for youth (ages 7-22) with ASD and ID is important for advancing the dissemination of evidence-based practices (EBPs) and decreasing treatment disparities in this population. We collected usual care information from expert ASD providers in order to assess self-reported familiarity and use of common practices for treating youth with ASD and ID.

Methods: Expert ASD providers (*N*= 53) representing multiple disciplines across 5 sites were recruited via purposeful sampling. Experts reviewed and suggested revisions to 49 literature-derived practices through a two-round Delphi poll, then rated a revised list of 55 practices on familiarity and use across three domains: anxiety, externalizing behaviors, and social skills. Round 2 ratings of experts who endorsed frequently treating youth with comorbid ID (*n*= 26) were compared with those of experts who never or rarely treat youth with comorbid ID (*n*= 27).

Results: Chi-square analyses indicated that experts who frequently work with individuals with ASD and ID are significantly less familiar with *Psychoeducation* (c2= 4.337, p= .037). In treating anxiety, they are more likely to use *Functional Behavior Assessment* (c2= 4.48, p= .034) and *Suppression Approach* (c2= 4.971, p= .026) and less likely to use *Self-Management* (c2= 3.927, p= .048). In treating externalizing behaviors, experts who work with youth with ID are more likely to use *Didactic Teaching* (c2= 4.369, p= .037), *Shaping* (c2= 4.043, p= .044), *Stimulus Control* (c2= 7.619, p= .006), *Suppression Approach* (c2= 3.846, p= .050), and *Token Economy* (c2= 4.609, p= .032). In treating social skills, they are more likely to use *Providing Choices* (c2= 5.88, p= .015), *Noncontingent Reinforcement* (c2= 5.299, p = .021), *Response Cost* (c2= 4.886, p= .027), *Stimulus Control* (c2= 8.292, p= .004), *Suppression Approach* (c2= 7.127, p = .008), *Imitating the Child* (c2= 4.9, p= .027), and *Communicative Temptations* (c2= 3.886, p= .049), and less likely to use *Self-Management* (c2= 8.265, p= .004).

Conclusions: Findings suggest that expert community providers who commonly treat youth with ASD and ID are more likely to use specific discrete intervention strategies, particularly suppression and stimulus control, for treating anxiety, externalizing behaviors, and social skills than those who treat youth with ASD without comorbid ID. This information could inform research on the dissemination and implementation of EBPs for youth with ASD and ID.

321 **218.321** What Services Are Families of Children with Executive Function Challenges Getting? What Do Parents Say They Want?

M. Troxel[1], *M. D. Powers*[2], *Y. Myrick*[3], *J. F. Strang*[4], *C. E. Pugliese*[3], *L. Kenworthy*[3] *and L. Anthony*[1], *(1)University of Colorado, Denver, Aurora, CO, (2)Children's National Health System, Rockville, MD, (3)Children's National Health System, Washington, DC, (4)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC*

Background:

Parents of children with neurodevelopmental disorders commonly report unmet needs in regard to the treatment and management of their child's diagnosis (Brown et al., 2012; Hodgetts, Zwaigenbaum & Nicholas, 2015). While parent trainings are becoming integrated into the service array as an evidenced-based resource (e.g., Postorino et al., 2017; Loren et al., 2015), there are substantial barriers to these services that limit parent engagement and involvement (Martinez et al., 2018). Furthermore, an understanding of the services that parents truly want is lacking.

Objectives:

To investigate child-related services families are receiving, services and supports parents want, and parent availability to participate in school-based parent trainings.

Methods:

We administered online surveys nationwide to 125 parents of children in 3rd through 5th grades with executive function (EF) problems.

Results:

Results show that 5.6% of parents of a child with an ASD or ADHD diagnosis (N=107) reported they had attended a parent training on EF, and 16.3% reported they had attended a school-sponsored parent training of any kind. Parents of children with Individualized Education Plans (IEPs) (N=57) were more likely to have attended a school-sponsored parent training than those whose children did not have IEPs (χ^2=4.054). Parents of children who received services outside of school (N=42) were more likely to report greater child EF support than those who did not receive outside services

(χ^2=7.588). Parents of children with an ASD diagnosis (N=45) reported that their child was more likely to receive EF support compared to those whose child had an ADHD diagnosis (N=60), or those whose child had undiagnosed EF difficulties (N=18; χ^2=11.78). Eighty-six percent of parents reported that they would like more training opportunities. More specifically, parents reported that they want, and realistically think they can devote, between 0 to 1000 hours to training, with a median of 10.0 hours, per year. Only four parents (3.2%) said they want zero hours of school-based training per year and three (2.4%) said they realistically are able to devote zero hours to training.

Conclusions:

While rates of EF parent training attendance are relatively low, this is likely due to limited opportunities for training. In this study, parents reported that they would like to receive more training. This information should be used to support increased provision of services to families of children with EF problems.

322 **218.322** What Services Do Preschoolers with ASD Utilize? Comparing Services in Two US Cities

F. Huddleston[1], *A. S. Nahmias*[1], *M. Maye*[2], *S. F. Vejnoska*[3], *A. C. Stahmer*[4], *S. R. Rieth*[5], *J. Suhrheinrich*[5], *S. R. Crabbe*[6] *and D. S. Mandell*[7], *(1)MIND Institute, UC Davis Medical Center, Sacramento, CA, (2)Psychiatry, University of Pennsylvania, Philadelphia, PA, (3)University of California, Davis, Sacramento, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (5)San Diego State University, San Diego, CA, (6)University of Pennsylvania, Philadelphia, PA, (7)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background:

Although 48 states in the United States have enacted laws requiring health plans cover autism-specific therapies, there is high variability in the legal requirements across states (Baller et al, 2015; Autism Speaks, 2018). Additionally, there are large disparities in access to services for children with ASD in minority groups (Mandell et al, 2002). Although the education system plays a critical role in providing services for preschoolers with ASD (Brookman-Frazee et al., 2009), increasingly, families are accessing additional services through insurance-funded programs. Recent research examining the effect of autism insurance mandates indicates an increase in insurance-based services, but also significant ongoing barriers to expanding access to services to meet need (Baller et al., 2015; Candon, 2018). More information is needed to understand how demographic factors and state and local policies affect children's service utilization. Due to ongoing challenges with service access (Thomas et al, 2007), it may be useful to examine and compare regional service utilization in a diverse sample in order to understand where to intervene to improve access for underserved youth.

Objectives:

Explore differences in service use based on sociodemographic and geographic factors by comparing parent report of non-school based ASD services from preschoolers in Pennsylvania and California.

Methods: Data from two longitudinal studies of preschool children (3 – 5 years old) with ASD receiving publicly funded educational services in Philadelphia, Pennsylvania (N = 71; 83% male; 55% Black/African American; 18% Hispanic/Latino) and San Diego, California (N = 144; 80% male; 36% Hispanic/Latino; 2.8% Black/African American) were analyzed. Parents reported their children's current non-school based services (e.g., speech therapy, occupational therapy) via interview (Philadelphia) or questionnaire (San Diego). Chi-square tests of independence were run to examine differences.

Results: Table 1 summarizes the percent of preschoolers with ASD whose parents reported receiving specific services outside of school programs in both locations. When compared to children in CA, children in PA received significantly less behavioral therapy, but significantly more mental health services (*p*s <.001). In addition, more children in CA received medication than in PA (*p* <.02). Further analyses will explore child and family characteristics (e.g. race/ethnicity, socioeconomic status) and state policy differences as predictors of service use.

Conclusions: Preliminary results suggest that there are differences in service utilization for preschoolers with ASD in CA and PA. These utilization differences may be related to sociodemographic characteristics of the families or differences in service availability due to state policies.

323 **218.323** "We Are Doing the Best We Can" - Service Provider and Government Stakeholder Perspectives on Autism Spectrum Disorder Services in the Western Cape Province of South Africa

S. Pillay[1], *M. Duncan*[2] *and P. J. de Vries*[3], *(1)Health Sciences, University of Cape Town, Cape Town, South Africa, (2)Occupational Therapy, University of Cape Town, Cape Town, South Africa, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa*

Background:

Meeting the educational needs of school aged children with autism spectrum disorder (ASD) is a major challenge in South Africa. In the Western Cape Province, for example, the rate of referrals to educational services significantly outweighs capacity in the system. An analysis of the Western Cape Education Department database performed by us in 2016 found 940 children with ASD in the system, and 744 children waiting for school placement. Alarmingly, numbers on the waiting list showed an increase of 276% over a five-year period. Existing services and structures are therefore under increasing pressure and scrutiny to identify solutions.

Objectives:

The objective of the study was to examine multi-stakeholder perspectives of the challenges and proposed solutions to meet the educational needs of children with ASD and their families. Here we focused on the perspectives of clinical service providers and government stakeholders.

Methods:

Semi-structured interviews were conducted with eight ASD service providers and six stakeholders from the Western Cape Departments of Education, Health and Social Development. Thematic analysis was used to identify emerging themes and related categories from each stakeholder group, before identifying critical domains of synergy and contestation in the two groups.

Results:

Service providers shared information about service related challenges in meeting the needs of individuals with ASD across the spectrum and across the lifespan. The theme '*We are failing the child*' described how decisions made were reactive rather than proactive, and not always in the best interest of the child with ASD and their families. The theme '*Everyone is working in silos*' captured the frustrations of providers about

perceived poor collaboration between government departments.

Government stakeholders from different departments displayed varying degrees of knowledge and accountability for the ASD situation in the province with some departments assuming more responsibility than others as demonstrated in the theme '*They are all not on the same page*'. In the absence of an integrated national or provincial strategy for ASD, some departments described the approach to service delivery as '*Putting out little fires everywhere'.* Government stakeholders concurred that collaboration was a problem and that all government departments should be working together to find solutions.

Two integrated, overarching themes emerged from both constituencies. '*Autism is an expensive diagnosis'* highlighted stakeholder perspectives that autism services demanded very significant physical and human resources. '*We are doing the best we can*' described how, despite having an overburdened system and over-stretched resources both stakeholder groups felt that the Western Cape Province was doing better than other provinces in the country in terms of ASD services by having a consolidated database, outreach teams and establishing new ASD units at some special schools.

Conclusions:

The study highlighted various challenges in meeting the educational needs of children with ASD in South Africa. Few, if any, tangible solutions were proposed by stakeholders. Findings suggest the urgent need for a multi-stakeholder process, crucially including the voices of families who live with ASD, to generate comprehensive, evidence-based, sustainable and scaleable policies and practices to meet the educational needs of all children with ASD.

324 **218.324** Echo Autism Transition: An Innovative Approach for Increasing Access to Healthcare for Adolescents and Young Adults with Autism Spectrum Disorder

B. A. Malow[1], *G. Stobbe*[2], *N. C. Cheak-Zamora*[3], *A. Curran*[4], *K. Davis*[5], *A. Hess*[6], *R. L. Loftin*[7], *M. O. Mazurek*[8], *M. Mirza-Agrawal*[9], *M. Tapia*[10] *and K. Sohl*[11], *(1)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (2)Psychiatry & Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA, (3)Health Sciences, University of Missouri, Columbia, MO, (4)Thompson Center for Autism, Columbia, MO, (5)Seattle Children's Autism Center, Seattle, WA, (6)The Ohio State University/CAST, Hilliard, OH, (7)Department of Psychiatry and Behavioral Sciences, Feinberg School of Medicine, Northwestern University, Chicago, IL, (8)University of Virginia, Charlottesville, VA, (9)Florida International University, College of Medicine/EMBRACE, Miami, FL, (10)University of Texas at Austin, Austin, TX, (11)Thompson Center for Autism, University of Missouri - School of Medicine, Columbia, MO*

Background:

Dramatic increases in the prevalence of autism spectrum disorder (ASD) have been accompanied by a rising tide of adolescents with ASD who are entering adulthood. With well-documented shortages in the provider workforce, training of community healthcare providers to serve the unique needs of transition-age youth with ASD in geographic, racial, ethnic, and economically diverse communities requires novel approaches.

Objectives:

Project Extension for Community Healthcare Outcomes (Project ECHO) framework is an approach that has proven successful in increasing the role and expertise of the practicing community-based primary care provider (PCP). Project ECHO uses secure multi-point videoconferencing technology to create a learning community, connecting PCPs in local communities ("spokes") to an interdisciplinary team of experts ("hub") through regular recurring sessions. During these sessions, learning is facilitated through brief evidence-based didactics, case-based learning (during which PCPs present their own cases for discussion and co-management), collaborative mentorship, and guided practice.

In ECHO Autism (*Clinical Pediatrics, 56(3)*: 247-256, 2017), significant improvements were observed in self-efficacy, adherence to ASD screening guidelines, and use of ASD-specific resources, with high satisfaction reported by participants. We now describe the development and implementation of an innovative approach to increasing access to healthcare for adolescents with ASD, entitled ECHO Autism Transition.

Methods:

In Summer 2018, the planning team, including hub team members, developed a template for presentation along with didactic presentations and materials to measure outcomes. In Fall 2018, PCPs were recruited for the program through several routes including community-based referral sources, national provider organizations, and social media. A total of 12 weekly 1-hour sessions are being conducted, in which a series of didactic presentations are given by hub team members on topics related to transition-age years. Case presentations are delivered by spoke participants that allow for discussion between hub members and participants. Recommendations are discussed and formally given to the case presenter. Recommendations and resources are available online for participants to access at any time. Participants receive CME for participation, and outcome measures regarding participant satisfaction, confidence, and knowledge are being collected (to be completed in early 2019).

Results:

A total of 15 PCPs were recruited nationally and meet weekly for the ECHO sessions. Didactic sessions include topics such as medical and psychiatric co-occurring conditions, behavior management in primary care, supporting families through transition, life skills development, supporting the self-advocate, guardianship, education, housing, and sexuality. Case presentations highlight challenges facing adolescents and their families as they transition to adulthood. Data regarding participation rate, provider satisfaction, provider confidence and knowledge, and common themes of case presentations are being collected and will be presented.

Conclusions:

To our knowledge, ECHO Autism Transition is the first of its kind to focus on the transition to adulthood in ASD. We have successfully developed and launched a case presentation template, outcomes measures, and didactic presentations and have enrolled a cohort of participants. We will present additional outcomes data paralleling that published previously for ECHO Autism. ECHO Autism initiatives illustrate evidenced-based approaches in building workforce capacity and access to quality care in individuals with ASD.

Poster Session
219 - Social Neuroscience
5:30 PM - 7:00 PM - Room: 710

325 **219.325** ASD Symptoms Are Associated with Reduced LPP As Youth Learn about Inconsistent Peers during Social Interactions.

T. Clarkson[1], *C. M. Keifer*[2], *M. D. Lerner*[3], *B. D. Nelson*[2] *and J. M. Jarcho*[1], *(1)Psychology, Temple University, Philadelphia, PA, (2)Stony Brook University, Stony Brook, NY, (3)Psychology, Stony Brook University, Stony Brook, NY*

Background: Social skills deficits are a primary autism spectrum disorder (ASD) symptom. Failure to learn about others in new or unpredictable social situations may contribute to this deficit. Prediction and reevaluation of others during iterative social interactions is essential for learning (Behrens, Hunt, Woolrich, & Rushworth, 2008) to appropriately engage in social interactions, but is less essential once learning has occurred (Davis & Levine, 2013). Quicker learning to predict another's behavior may improve social skills in individuals with ASD symptoms. The late positive potential (LPP), an event-related potential associated with evaluating and attending to emotional stimuli (Hajcak et al., 2009), is enhanced to unpleasant social stimuli and reduced after reevaluation (Foti & Hajcak, 2008). Individuals with ASD exhibit a blunted LPP to social stimuli (Benning et al., 2016). Yet, little is known about how ASD symptomology relates to the changes in the LPP as individuals *learn* about their peers during social interactions.

Objectives: Examine if learning moderates relations between ASD symptomology and changes in the LPP over iterative social interactions.

Methods: Electrophysiological responses were measured via EEG as neurotypical youth (N = 54, M_{age}=12.11, SD_{age}=2.91; 22 male) were evaluated by purported peers who provided consistent (100% positive *or* negative) or inconsistent (50% positive and negative) evaluation in a Virtual-School context. Participants randomized to the control condition were informed of each peer's reputation for being nice, mean, or unpredictable prior to entering the Virtual-School (N=29). Those in the learning condition learned each peer's reputation through their evaluation alone (N=25). In this group, learning was confirmed based on ratings participants provided about each peer after every two interactions (nice-vs-unsure-vs-mean). Change scores for the LPP after social evaluation (400-1000ms) were calculated by subtracting early (first 48) from late (last 48) interactions. Moderation analyses determined the extent to which changes in LPP (X) differentially related to ASD symptoms (Y; subscales of the SRS-2, Constantino & Gruber, 2005) in the learning and the control groups (W).

Results: The learning group had greater changes in peer rating between early and late interactions for all peers, demonstrating learning occurred (*p's*<0.05*)*. Group moderated the relation between change in LPP to inconsistent peer evaluation and ASD symptoms of social awareness, communication, and cognition (*B's*>0.49, *p's*<0.05). Specifically, in the learning group, reduced LPP to inconsistent social evaluation in late-vs-early interactions was associated with more severe ASD symptoms. This relation was not observed in the control group. No effects were observed for consistent social interactions (*B's*<0.34, *p's*>0.16).

Conclusions: More severe ASD symptoms are associated with reduced LPP responses to inconsistent social evaluation when individuals learn about their peers through first-hand experience. Reduced LPP responses may indicate social evaluation from inconsistent peers becomes less salient throughout learning for those with ASD symptoms. This may increase reevaluation and difficulties predicting inconsistent peers which could exacerbate problems generalizing social skills to novel social situations (Bellini, Peters, Benner, & Hopf, 2007). Thus, targeting learning in novel or inconsistent social interactions may enhance the generalization of social skills in those with ASD symptoms.

326 **219.326** Altered Functional Connectivity during Social Interaction in Children with Autism Spectrum Disorder

Y. Xiao[1,2], *D. Alkire*[1,2], *D. Moraczewski*[1,2] *and E. Redcay*[1,2], *(1)Department of Psychology, University of Maryland, College Park, MD, (2)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD*

Background: Individuals with autism spectrum disorder (ASD) have difficulties engaging in reciprocal social interaction, which might be due to both atypical reward processing and mental state reasoning, or mentalizing (Chevallier et al., 2012; Pelphrey et al., 2011). While previous explorations of social processing in ASD were mainly focused on activation and conducted in non-interactive contexts, recent studies have begun to address this question during real-time social interaction (Jasmin et al., 2018; Redcay et al., 2013). However, research has not examined the integration within and between mentalizing and reward brain networks during social interaction in children with ASD, especially in middle childhood, an important period for social and cognitive development.

Objectives: We aimed to investigate functional correlations within and between the mentalizing and reward networks during social interaction in children with ASD compared to neurotypical (NT) children.

Methods: Preliminary data from an ongoing study are reported from 12 children with ASD (10 males, 12.3 ± 0.91 years) and 12 NT children (11 males, 13.01 ± 1.44 years), matched on age, gender, and IQ. We used an interactive game in which children predicted responses of either a social partner or a story character based on either mental or non-mental state information (Alkire et al., 2018).

Data preprocessing was performed using AFNI (Cox, 1996), with functional images normalized to a child template (Fonov et al., 2011) and effects of head motion minimized (i.e., censor volumes exceeding 1 mm framewise displacement (FD); remove runs >10% censored volumes or mean FD > 0.5 mm). Controlling for head motion, functional connectivity was calculated by estimating trial-wise beta series (Mumford et al., 2012; Rissman et al., 2004) of regions in the mentalizing and reward networks (Neurosynth; Yarkoni et al., 2011) for each condition (Figure 1). We examined effects of group (ASD vs. NT), social context (social partner vs. story character), and their interaction on the mean connectivity within and between the mentalizing and reward networks. Further, we verified specificity of the effects within and between the mentalizing and reward networks through a supplemental analysis within the mirror neuron and salience networks, which are also involved in social interaction (Redcay and Warnell, 2018).

Results: We observed group*social context interactions on mean connectivity within the mentalizing network ($F(2,23) = 4$, $p = .0496$) and between the mentalizing and reward networks ($F(2,23) = 4.01$, $p = .0495$). These effects were driven by greater connectivity during social interaction in NT children (mentalizing network: $F(1,11) = 9.38$, $p = .004$; between networks: $F(1,11) = 6.41$, $p = .017$) but not in children with ASD. Our specificity analyses demonstrated no effects within the mirror neuron or salience networks.

Conclusions: We demonstrated that brain functional connectivity within and between the mentalizing and reward networks is modulated by social-interactive context in NT children but not in children with ASD. These preliminary results suggest reduced neural sensitivity to social interaction in children with ASD compared to NT children, which provides new insights into the brain basis underlying social difficulties in ASD during real-world social interaction.

327 **219.327** Analysis of Neural Dynamics during Social Interaction with a Virtual Avatar in Autism

A. Bánki[1], *A. Lefebvre*[2], *D. A. Engemann*[3], *A. Pedoux*[4], *F. Amsellem*[5], *R. Delorme*[6] *and* ***G. Dumas***[7], *(1)Faculty of Psychology, University of Vienna, Vienna,*

Austria, (2)Institut Pasteur, Paris, France, (3)Parietal Team, INRIA, Gif-sur-Yvette, France, (4)Institut de psychologie, Université Paris Descartes - Sorbonne Paris Cité, Paris, France, (5)Pasteur, Paris, France, (6)AP-HP, Robert-Debré Hospital, Child and adolescent Psychiatry unit, Paris, France, (7)Human Genetics and Cognitive Functions Unit, Institut Pasteur, Paris, France

Background:
Social interactional neuroscience aims to explore the neural mechanisms underlying our social interactions, in order to better understand human behaviour and to reveal processes that are responsible for social impairment, one of the primary characteristics of neurodevelopmental disorders such as Autism Spectrum Disorder (ASD).

Objectives:

The aim of this study is to provide a more precise understanding on impaired reciprocal social interactions in ASD with the perspective of developing electroencephalography (EEG) based diagnostic methods in current child and adolescent psychiatric practice.

Methods:

In this study, neural dynamics of 40 typical controls (CTR) and 40 participants with ASD (Table 1) were recorded with high-density EEG (HD-EEG) during resting state and a social interactive task, where subjects coordinated their finger movements with a virtual avatar designed to behave like a human (Human Dynamic Clamp [HDC]). Neurophysiological data was analysed in order to compare the neural dynamics between the two groups. We computed Power Spectral Density (PSD) for each participant and investigated anatomo-functional differences in the usual frequency bands (Hz): Delta (1-4), Theta (4-7), Alpha (Low: 7-10, High: 10-13), Beta (13-30) and Gamma (30-45) and 8 brain lobes (Left frontal, Right frontal, Left parietal, Right parietal, Left occipital, Right occipital, Left temporal and Right temporal). Motor behaviour performances and verbal reports about the avatar's behaviour were also assessed to compute sensorimotor and socio- cognitive metrics.

Results:

Social interaction with a virtual avatar revealed in both CTR and ASD groups a decrease in the Alpha band over the parietal lobes and an increase in the Beta and Gamma bands over the occipital lobe. However, we observed: 1) a greater High-Alpha suppression over the frontal lobe in ASDs, potentially reflecting inhibitory effects, and 2) higher increase in the Beta and Gamma bands over the occipital lobe in CTRs, potentially reflecting attentional effects; both observations are consistent with our previous findings. Behavioural analyses found small differences between groups, for sensorimotor scores ('Phase Coordination', 'Amplitude Coordination', 'Task Realisation') but more specially for socio-cognitive metrics ('Intentionality', 'Theory of Mind').

Conclusions:

These results support the development of social interactive tasks for the exploration of the neurophysiology of autism and its link to social cognition. The Human Dynamic Clamp allows to narrow the intra-individual variance while revealing inter-group differences. Our findings demonstrate that it can be used in clinical context and serves as a new instrument for the evaluation of on-line and off-line modes of social cognition. The HDC can also contribute to the improvement of existing therapeutic interventions for ASD that exploit virtual reality and social robotics.

328 **219.328** Associations between Changes in Social Visual Engagement and White Matter Microstructure during the First 6 Months of Life.

A. L. Ford[1], *L. Li*[2], *W. Jones*[3], *A. Klin*[3] *and S. Shultz*[3], *(1)Marcus Autism Center, Emory University School of Medicine, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta, Emory University, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Attention to eyes—a critical skill that guides typical socialization—is already in decline by the second month of life in infants later diagnosed with Autism Spectrum Disorder (ASD), with steeper decreases in eye fixation associated with more severe social disability (Jones & Klin, 2013, *Nature*). In contrast, typically developing (TD) children *increase* their attention to eyes throughout infancy, establishing a foundation for continued social visual engagement and brain specialization. The neural systems associated with this basic mechanism of social adaptive action are currently unknown, even in typical development. Identifying associations between trajectories of social visual engagement and trajectories of brain maturation in typical infancy is an important step towards understanding how deviations from these trajectories may lead to the emergence of social disability in ASD.

Objectives: To identify associations between trajectories of white matter microstructure and trajectories of social visual engagement in the first 6 months of life.

Methods: Diffusion MRI and eye-tracking data were collected prospectively and longitudinally in the same infants (n=32, 10 female) at 3 and 6 pseudorandom time points, respectively, between birth and 6 months. All participants were full-term, healthy infants with no family history of ASD or developmental delay and no known medical or genetic conditions. Diffusion data were collected with the following parameters: multiband factor of 2 with GRAPPA of 2; 2mm isotropic spatial resolution; b=0/700 s/mm^2, 61 diffusion directions. Atlas-based tractography was used to delineate major white matter tracts: arcuate fasciculus, corpus callosum – body, genu, and splenium, inferior fronto-occipital fasciculus, and inferior longitudinal fasciculus. Fractional anisotropy (FA) values were generated for each tract. Eye-tracking data were collected while infants viewed scenes of actress caregivers engaging in naturalistic interaction and percentage of fixation time for each of four regions-of-interest (eyes, mouth, body, background) was calculated. Growth curves were fit using functional principle component analysis (FPCA) and Functional Linear Regression using Principal Component Analysis tested associations between longitudinal trajectories (Yao, Müller, & Wang, 2005, *Ann. of Statistics*).

Results: Functional regression analyses revealed significant coefficients of determination (p<.05) between growth curves of eye-looking and FA in the genu of the corpus callosum (CCg) and inferior fronto-occipital fasciculus (IFOF). No other associations were found. Examination of the estimated regression functions (Figure 1C) revealed that percentage of fixation time on eyes at earlier developmental time points positively contributes to FA in the CCg and IFOF at later developmental time points (Figure 2).

Conclusions: This study provides the first demonstration of associations between trajectories of white matter development and social visual engagement in the first months of life. Early attention to eyes—a basic mechanism of social adaptive action that is disrupted in ASD—is positively associated with later development of the CCg and IFOF, tracts that form the structural foundation of pathways involved in voluntary goal-directed

attention. These findings indicate that developing visual networks may be particularly responsive to experiential input involving the eyes of social partners and suggest a process by which early divergence from normative experience may lead to atypical patterns of white matter development in ASD.

329 **219.329** Atypical Associations between Gesture Processing, Performance and Social Symptoms in Autism Spectrum Disorder

E. Fourie[1,2], *E. R. Palser*[3], *J. Pokorny*[4], *M. Neff*[5,6] *and S. M. Rivera*[1], *(1)Department of Psychology, University of California, Davis, Davis, CA, (2)Center for Mind and Brain, University of California, Davis, Davis, CA, (3)Clinical, Educational and Health Psychology, UCL, London, United Kingdom, (4)UC-Davis, Davis, CA, (5)Department of Computer Science, University of California, Davis, Davis, CA, (6)Department of Cinema and Digital Media, University of California, Davis, Davis, CA*

Background: Individuals with autism spectrum disorder (ASD) demonstrate impairments in nonverbal communication, including diminished use of gestures, gesturing errors and difficulties with imitation. One potential explanation for these impairments is a deficit in perceiving biological motion (BM). Decreased visual sensitivity to BM may inhibit adequate processing of dynamic non-verbal social cues, like gestures. This perceptual dysfunction may impede learning and subsequent performance of these actions, resulting in nonverbal communication deficits and atypical social development in ASD.

Objectives: The goal of this study was to examine the brain-behavior relationships between neural activity during gesture processing, gesturing abilities and social symptoms to identify atypical mechanisms underlying perception-action coupling and how this abnormality may relate to compromised social development in ASD.

Methods: Participants included 15 children and adolescents with ASD and 16 typically-developing (TD) controls, ages 9 to 17. During the fMRI task, participants viewed animations (created by applying digitalized motion capture of actions performed by an actor to a 3D human model) of both functional (e.g. driving) and communicative (e.g. waving) gestures. Gesture performance was assessed outside the scanner using a charade-style paradigm, in which participants enacted a series of 15 familiar actions (e.g. brush teeth), which were double-coded by raters blind to diagnosis for quality of specific components (e.g. limb movement, hand posture). A parent-report measure of social functioning, the Social Responsiveness Scale (SRS-2), was also collected.

Results: In whole brain analyses, both groups showed activation of lateral occipital-temporal cortex (LOTC), a region sensitive to both body motion and form. Beta parameters were averaged from 6-mm radius spherical regions of interest (ROI) centered around individual peak coordinates in bilateral LOTC. This ROI analysis revealed that the ASD group had reduced activity in left LOTC compared to controls ($p < .001$). In order to explore this group difference in neural activity, we examined associations between activation, gesture performance and social symptomology. The TD group showed a negative correlation between left LOTC activity and SRS scores ($r = -.49$, $p < .05$), not present in the ASD group ($r = -.09$, $p = .76$). Gesture performance was also negatively correlated with SRS scores in both groups, significant only in the TD group ($r = -.60$, $p < .05$; ASD: $r = -.57$, $p = .05$). These associations demonstrate links between social impairment and both diminished processing and performance of gestures. In a subset of participants who completed both fMRI and behavioral components (8 ASD, 12 TD), activity in left LOTC was positively associated with gesture performance in the TD group ($r = .65$, $p < .05$) but not the ASD group ($r = .08$, $p = .86$).

Conclusions: These findings suggest that in typical development, increased neural processing of gestures is associated with better gesture performance and social functioning, supporting a link between perception of dynamic social cues, subsequent gesturing abilities and sociability. The absence of such relationships in the ASD group may reflect dysfunction in a perception-action coupling mechanism that leads to cascading effects on atypical social development.

330 **219.330** Decreased Ventral Striatum Activation during Receipt of Social Response in Children with ASD and Co-Occurring Social Anxiety Symptoms

H. A. Yarger[1], *L. A. Kirby*[2], *D. Moraczewski*[3], *K. R. Warnell*[4], *K. A. McNaughton*[5], *A. Cechaviciute*[1], *D. Alkire*[5] *and E. Redcay*[3], *(1)University of Maryland, College Park, MD, (2)Yale Child Study Center, New Haven, CT, (3)Department of Psychology, University of Maryland, College Park, MD, (4)Department of Psychology, Texas State University, San Marcos, TX, (5)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD*

Background: Children and adolescents with Autism Spectrum Disorder (ASD) are frequently diagnosed with co-occurring anxiety disorders, with meta-analytic results indicating social anxiety disorder (SAD) co-occurs in approximately 16.6% of children and adolescents with ASD (van Steensel, Bogels, & Perrin, 2011). Research focused on SAD in adults has pointed to reduced neural activity in the ventral striatum (VS) during social reward processing when being observed by others (Becker, Simon, Miltner, & Straube, 2017). In one study comparing activation during receipt of social versus monetary reward in adults with ASD or SAD, adults with SAD exhibited greater amygdala activation relative to ASD in response to social reward (Richey et al., 2014). Little work has explored the co-occurrence of social anxiety (SA) symptoms and ASD and its impact on neural activation, especially in children during a real-time social interaction.

Objectives: The current study investigated whether co-occurring SA symptoms in children with ASD were associated with amygdala and VS activation in response to social versus nonsocial engagement during a real-time social interaction.

Methods: Participants were 26 children with a confirmed diagnosis of ASD aged 7 to 15 years ($M = 12.3$, $SD = 1.9$). Symptoms related to SA were assessed using the social phobia scale of the Screen for Child Anxiety Related Emotional Disorders, parent version (SCARED; Birmaher et al., 1997). SA scores ranged from 1 to 18 ($M = 7.0$, $SD = 4.3$). Neural activity within the VS and amygdala in response to social reward was assessed using a socially interactive fMRI paradigm (Warnell, Sadikova, & Redcay, 2018). Participants chatted with either a peer or a computer (social interaction context) that contingently responded to their interest (engaged) or was away (non-engaged), creating a 2 (peer vs. computer) x 2 (engaged vs. non-engaged) design. We were interested in the comparison between social contingency (i.e., peer-engaged) and nonsocial contingency (i.e., computer-engaged). We hypothesized that there would be a positive association between SA symptoms and amygdala activation and a negative association between SA symptoms and VS activation during the peer-engaged relative to the computer-engaged context.

Results: Results supported a negative association between levels of SA symptoms and activation in the inferior ($r = -.54$, $p = .01$) and superior VS ($r = -.50$, $p = .01$) when receiving a socially contingent (i.e., engaged) response from a peer versus the computer. No significant association was observed between SA symptoms and amygdala activation during peer versus computer response ($r = -.13$, $p > .05$).

Conclusions: Results extend previous work in social anxiety by demonstrating a negative relation between social anxiety and social reward

activation in the striatum, but not the amygdala, in children with ASD. Further, unlike previous studies, these social reward effects were found within a naturalistic peer interaction which may have greater relevance to real-world social interaction.

331 **219.331** Distinct Neural Signatures in Social Brain Circuitry in Female Children with ASD

D. Abrams[1], *A. Padmanabhan*[1], *A. E. Baker*[1], *S. Karraker*[2] *and V. Menon*[3], *(1)Stanford University, Palo Alto, CA, (2)Stanford University School of Medicine, Palo Alto, CA, (3)Stanford University, Stanford, CA*

Background: Autism spectrum disorder (ASD) affects 1 in 189 girls in the United States and is characterized by pervasive deficits in social communication. Due to the greater incidence of ASD in males, the vast majority of research into the behavioral and brain bases of autism have relied on data collected predominantly from male participants. Unfortunately, this has precluded a comprehensive understanding of autism in females, which is critical for developing autism treatment approaches for girls. Of particular interest is that, on average, females with ASD have greater social communication abilities compared to males. This result is consistent with the hypothesis that females with ASD are "protected" from more severe forms of social dysfunction.

Objectives: Here, the goal of our work is to provide important new information regarding the behavioral and neural profiles of girls with ASD with a focus on identifying brain circuitry which are intact relative to boys with ASD.

Methods: We examined the integrity of brain systems underlying a critical aspect of social function that is impaired in ASD: the processing of human voices. Specifically, we examined intrinsic functional connectivity of the voice-selective brain network, anchored in bilateral superior temporal sulcus, in a group of 13 girls with ASD (7-12 y/o) and a comparison group of 13 boys with ASD matched on age, IQ, motion, and ADOS Social Affect. We are also analyzing similar brain and behavioral data from the ABIDE-2 dataset and vocal task-based brain imaging data previously collected by our group.

Results: Preliminary data provide evidence for differential recruitment of voice processing, reward, and affective brain systems in females with ASD. Consistent with a previous study (Abrams et al, *PNAS*, 2013), boys with ASD showed hypo-connectivity of the extended voice-selective network, which includes reward and salience regions. Strikingly, girls with ASD show hyper-connectivity within this network: connectivity in females with ASD exceeded both males with ASD as well as TD boys and girls.

Conclusions: Results suggest that girls with ASD show a distinct neural signature characterized by hyper-connectivity of the extended voice-selected network, and provide preliminary evidence that increased connectivity of voice-reward circuitry may serve as a neuroprotective mechanism for females with ASD. Findings provide new and important information regarding social brain circuitry in girls with ASD, and may contribute to the development of new approaches for identifying and treating affected girls.

332 **219.332** Effects of Oxytocin on Biological Motion Perception in Youth with ASD: A MEG Study

A. Korisky[1], *A. Goldstein*[1,2] *and I. Gordon*[3], *(1)Gonda Brain Research Center, Bar-Ilan University, Ramat Gan, Israel, (2)Department of Psychology, Bar Ilan University, Ramat Gan, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background:

The ability to recognize and prefer biological motion is highly conserved and typically developed within the first year of life and is believed to be critical for developing social skills and social understanding. Few studies have shown that infants and adults with autism spectrum disorders (ASD) failed to recognized biological motion, preferred a non-biological stimuli and present atypical brain activity during these tasks. Intranasal administration of the neuropeptide Oxytocin (OT) in individuals with ASD, has been found to modulate the activation of the mirror-neuron system (MNS) and other social-related brain regions, as well as attention to social cues. Here we focused on the influence of OT on the oscillatory brain activity in people with ASD during biological motion perception tasks, especially on alpha-band (mu) activity which is involved in socially-related tasks.

Objectives:

This study aims to explore the impact of OT on oscillatory brain activity in ASD using magnetoencephalography (MEG) during a well-validated biological motion paradigm. We focused mainly on alpha frequency which is considered to represent the MNS activity and correlates with social perception. We hypothesize that OT administration will modulate alpha-band activity in response to biological motion stimuli to resemble that of an aged matched typically developed (TD) group.

Methods:

As a part of an ongoing study, we present initial data from twenty youth with ASD (aged 12-18), who received a single dose of intranasal OT (24IUs) in a double-blind placebo-controlled study. Forty five minutes following administration, participants were scanned in the MEG. During each scan participants were presented with twelve point-light video clips, each 28 s long, presenting figure-performed human action (clapping hands, jumping) or a random movement. An aged-matched TD group serves as a baseline for comparison. For ethical reasons, TD participants did not receive OT/placebo.

Results:

Preliminary results indicate that in ASD, OT indeed modulate the power of alpha band during video clip observation. Calculating the ratio of alpha power between the biological and the random conditions revealed time-dependent differences in the pattern of alpha in sessions with and without OT. Still, with or without OT, ASD individuals presented neural activation patterns different from those of TD.

Conclusions:

Our results indicate that in ASD, OT can influence primary and preserved developmental abilities such as the ability to differentiate biological from non-biological movement. In line with former studies our results imply that OT may attune attention to social stimuli and thus might help to improve social difficulties. To the best of our knowledge this is the first MEG experiment addressing the influences of OT on youth with ASD. Studies of this shade light not only on behavior but also on specific neural component correlates with social perception and thus allow us to learn more about the complex phenomenon of ASD.

333 **219.333** Embodied Emotions in Autism Spectrum Disorder: Somatosensory Evoked Potentials Reveal Atypical Patterns of Neural

Activity during Perception of Emotional Expressions in ASD

M. Fanghella[1,2], *S. B. Gaigg*[1], *M. Candidi*[2], *B. Forster*[3] *and B. Calvo-Merino*[1], *(1)City, University of London, London, United Kingdom, (2)La Sapienza, Rome, Italy, (3)Psychology, City, University London, London, United Kingdom*

Background: Previous research has shown the independent contribution of the right somatosensory cortex to emotion recognition in the neurotypical individuals (Adolphs & Damasio 2000, Pitcher et al. 2008, Sel et al. 2014), supporting the embodied emotion hypothesis (Niedenthal 2007). Atypical patterns of responses to emotions in Autism Spectrum Disorder (ASD) have been shown in visual cortical areas, but embodiment processes in the Somatosensory Cortex have not been studied in this group yet.
Objectives: The current study investigates embodied simulation in the somatosensory cortex during emotion perception in ASD and typically developed (TD) adults.

Methods: We tested two groups of 20 TD and 20 ASD participants, matched for age (mean TD= 40.3, mean ASD = 41.62), gender (1 female, 19 male) and IQ (mean IQV TD = 114, ASD = 108.08, mean IQP TD = 117, ASD = 112.62). We presented neutral, afraid and happy faces to participants while their brain activity was recorded with a 64 channels EEG. In separate blocks, participants were either discriminating the emotion expressions (emotion task) or the gender (gender task) of the faces shown answering either an emotion or gender question on 20% of trials per task. On 50% trials participant received mechanical tactile stimuli on their left index finger after 105'' from visual onset. We measured the visual evoked potentials (VEPs) over the occipital lobe and the somatosensory evoked potentials (SEPs) over the Somatosensory Cortex. To isolate the pure somatosensory responses related to emotional processing from visual carryover effects, we subtracted the neural activity recorded in the visual-only condition (i.e., when no tactile stimuli were delivered) from activity in the tactile condition (following Sel et al., 2014).

Results: VEPs: we found significant main effects of emotion at P120, N170, and P300, and significant interactions between emotion, task and group at N170 and P300 ($p<.05$) with significant emotion effects only for the emotion task in both groups suggesting different visual processing of emotional expressions in the two groups during later processing stages. SEPs: Both group showed main effects of emotion in the right hemisphere in 60-80'', and in 80-100''. In 80-100'' time window, the effect was significant only in emotion task. Most importantly, we found significant interaction between emotion and group across all time windows between 100 and 220 ms, suggesting group differences at later processing stages. Follow up analyses showed that the main effect of emotion was persistent after 100'' in the right somatosensory cortex of the TD but not in the ASD group, suggesting differential recruitment of somatosensory cortex for embodied processing between the two groups.

Conclusions: Our study provides novel evidence of the contribution of the somatosensory cortex in emotion processing in individuals with Autism Spectrum Disorder. In particular, our results show the presence of embodiment in TD and ASD in early Somatosensory Evoked Potentials, but this effect was prolonged only in the TD group.

334 **219.334** Engagement and Disengagement of Visual Attention in Children with Autism Spectrum Disorder

C. McLaughlin[1], *S. Guillory*[1], *H. Grosman*[1], *E. Isenstein*[1], *E. Wilkinson*[1], *A. Rouhandeh*[1], *K. Meyering*[1], *V. Baskett*[1], *P. M. Siper*[1], *M. P. Trelles*[1], *A. Kolevzon*[1], *A. T. Wang*[1], *J. Buxbaum*[2] *and J. Foss-Feig*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder commonly characterized by abnormalities in social interaction, including decreased time spent looking at others, as well as abnormal reciprocal gaze and eye-contact. Previous studies using eyetracking technologies have identified general deficits in engagement and disengagement of visual attention in children with ASD. These findings suggest that abnormalities in social interaction may be, at least in part, the product of visual attention deficits. Such studies, however, have yet to investigate whether engagement of visual attention in children with ASD is differentially impacted by social and non-social stimuli.
Objectives: We sought to investigate whether visual attention in children with ASD is differentially engaged and disengaged by social and non-social stimuli.

Methods: Eyetracking data were recorded from 11 individuals with ASD and 10 typically-developing (TD) individuals, between the ages of 9 and 16. Participants fixated on a central stimulus for 1s, at which point a peripheral stimulus appeared to one side, either while the central stimulus remained on screen ("overlap" condition) or 250ms after the central stimulus disappeared ("gap" condition). Stimuli were presented in a randomized order, in grayscale, for both social (20 faces of children) and non-social (20 objects, including tennis ball, the Earth, cartwheel, etc.) conditions. Latency to saccade to the peripheral stimulus was recorded, and the gap effect (difference between average "overlap" and "gap" saccade latencies) for each participant was calculated. Reduced gap effect reflects deficits in engagement of visual attention; elevated gap effect indexes deficits in disengagement of visual attention.

Results: There was no significant difference in overall gap effect between ASD and TD participants ($p=.77$). For trials where both central and peripheral stimuli were of the same kind, there was no significant difference in gap effect between ASD and TD children (social:social $p=.34$; nonsocial:nonsocial $p=.73$). On the other hand, for trials with a social central stimulus and a nonsocial peripheral stimulus, there was a gap effect in TD children ($p<.01$) but none in children with ASD ($p=.39$). For trials with a nonsocial central stimulus and a social peripheral stimulus, there was a gap effect in children with ASD ($p<.01$), but none in TD children ($p=.30$).

Conclusions: An overall reduction in engagement of visual attention was not observed in ASD children compared to TD children, as there was no significant difference in gap effect between groups overall, or for trials in which both central and peripheral stimuli were of the same kind. However, ASD children displayed comparatively reduced engagement with social stimuli when presented with peripheral nonsocial stimuli, as well as increased engagement with nonsocial stimuli when presented with peripheral social stimuli. This finding suggests that children with ASD may have reduced engagement of visual attention that is specific to social stimuli, rather than a general deficit in visual engagement. It may provide a potential explanation for some of the abnormalities in social interaction observed in children with ASD.

335 **219.335** Frontal EEG and Thermal Asymmetries during the ADOS Predict ASD Severity

M. Jaime[1], *C. Harshaw*[2] *and I. M. Garcia Rojas*[3], *(1)Division of Science, Indiana University-Purdue University Columbus, Columbus, IN, (2)Department of Psychology, University of New Orleans, New Orelans, LA, (3)Division of Science, Indiana University-Purdue University, Columbus, Columbus, IN*

Background: Thermoregulatory and other homeostatic abnormalities are often noted in ASD. Such reports have received limited attention. However, they do merit investigation given that temperature impacts nearly all aspects of neuronal functioning, including EEG activity. Although aberrant brain activity has been implicated in the manifestation of social symptoms in ASD, thermoregulatory deficits also have the potential to give rise to cognitive dysfunction, including social deficits. For example, human and rodent studies have demonstrated that body and brain temperature undergo systematic changes during social interaction. Moreover, recent studies employing infrared thermography of the face have found that changes in facial temperature correlate with social-cognitive abilities in non-ASD samples.

Objectives: The objective of this exploratory study is to examine how individual variability in physiological measures, such as thermal and EEG asymmetry, acquired during real-life, person-to-person interaction may potentially serve to index the severity of social deficits in ASD.

Methods: In this ongoing study, non-invasive measures of frontal brain alpha, beta, and theta band hemispheric activity and thermal homeostasis are employed during live administration of the Autism Diagnostic Observation Schedule 2nd Edition (ADOS-2) via wireless EEG and high-resolution infrared thermography of the face, respectively. Eleven individuals with ASD (3 females) and 10 typically developing individuals (4 females) with an age range of 5-17 years have been tested thus far. EEG is recorded as one continuous epoch spanning the duration of the ADOS-2 session and pre-processed offline to remove ocular and movement artifact via EEGLAB. A left-right hemispheric asymmetry index score for frontal lateral (F8-F7) and frontal medial (FC6-FC5) electrode pairs is then calculated. Infrared thermographic images are also taken at the beginning, middle, and end of the ADOS-2 session. Average temperatures for specific ROIs (i.e., cheeks, eyes, medial canthi, and nose) are then extracted using IRFlash (ICI) and temperature asymmetry (T_{L-R}) is calculated by subtracting average maximum values in left ROIs from average maximum values in right ROIs.

Results: In a GLM, ADOS scores were predicted by diagnosis (t = -10.2, $p < .0001$), T_{L-R} (t = -3.5, $p < .006$), and diagnosis x T_{L-R} interaction (t = 2.4, $p < .04$). ADOS scores and T_{L-R} were significantly related for ASD (r = -.82, $p < .02$) but not TD (r = .13, $p = .78$) participants. EEG alpha and beta asymmetry at F7-F8 electrodes was also found to predict ADOS scores ($ps < .003$) in interaction with diagnosis ($ps < .05$). This relationship was, again, uniquely present for ASD participants indicating that left frontal asymmetry is associated with lower comparison scores on the ADOS-2. Finally, significant relationships were found between T_{L-R} and EEG asymmetry (alpha and theta) for the medial FC5-FC6 ($ps < .05$) but not the lateral F7-F8 electrodes ($ps > .05$).

Conclusions: The results of this study reveal an intriguing link between ASD severity, facial temperature asymmetry, and EEG asymmetry. Although the relation between all three variables appears to be complex, our findings thus far highlight the potential utility of physiological indices of social symptom severity in ASD.

336 **219.336** Heterogeneity in Alpha Rhythm Modulation in School-Aged Children with and without Autism Spectrum Disorder (ASD): Results from the ABC-CT Interim Analysis

S. Kala[1], *A. Naples*[1], *T. McAllister*[1], *C. Carlos*[1], *D. Stahl*[1], *K. Chawarska*[1], *G. Dawson*[2], *R. Bernier*[3], *S. Jeste*[4], *C. A. Nelson*[5], *S. J. Webb*[3], *C. Sugar*[4], *M. Murias*[6], *F. Shic*[7,8], *J. Dziura*[9], *C. Brandt*[9] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Boston Children's Hospital, Boston, MA, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (8)Pediatrics, University of Washington School of Medicine, Seattle, WA, (9)Yale University, New Haven, CT*

Background: The alpha rhythm is oscillatory EEG activity in the 8-13 Hz frequency range originating from sensorimotor cortex. Alpha rhythm is suppressed when individuals execute motor action; such modulation in the absence of motor activity is inferred to represent mirror neuron system activity. There is mixed literature regarding atypical alpha rhythm in children with Autism Spectrum Disorder (ASD). The present study analyzed EEG response to point-light displays of biological motion to examine the relationship between alpha modulation and clinical presentation in ASD.

Objectives: To contrast alpha modulation in children with ASD versus typical development in response to point-light biological motion and to explore its relationship with clinical characteristics. The examination of alpha modulation may be instrumental in understanding neural atypicalities that affect how children with ASD process and understand the social world around them.

Methods: Participants were children with ASD (n=105) and typically developing (TD) controls (n=55) aged 6-11 (Table 1). ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS-2) and the Autism Diagnostic Interview (ADI-R). Parents completed the Social Responsiveness Scale (SRS-2), a validated 65-item measure of social impairment in natural settings. Participants viewed a biological motion (biomotion) paradigm in which point-light displays (PLDs) of a human walking versus scrambled motion were presented randomly in four blocks of 26 trials (1025-1200 ms fixation crosshair followed by the 1000 ms stimulus). Alpha modulation was calculated as the difference in alpha power between the baseline fixation crosshair condition and the biomotion stimulus at central, frontal, and occipital electrode clusters over both hemispheres.

Results: Alpha modulation did not correlate with parent-reported social function (SRS-2) or ASD symptom severity (ADOS-2 Calibrated Severity Score; CSS) in TD males and males with ASD. However, in females with ASD (n=23), CSS correlated with alpha modulation over frontal (r=-0.469, p=0.024) and occipital (r=-0.443, p=0.034) regions, and SRS-2 scores correlated with alpha modulation over central (r=-0.444, p=0.039) and frontal (r=-0.496, p=0.019) regions. Correlations indicated that increased frontal, occipital, and central alpha modulation was associated with lower ASD symptomatology in females with ASD. In TD females (n=21), SRS-2 scores were positively correlated with alpha modulation over central (r=0.485, p=0.026) and frontal (r=0.439, p=0.047) regions, indicating that increased modulation was associated with greater social impairment. CSS correlates were not examined in TD females due to insufficient variation caused by floor effects.

Conclusions: Preliminary results suggest that alpha modulation during biological motion perception is distinct in males versus females with ASD and in females with and without ASD. However, females with and without ASD show opposing directionality and distinct scalp topography in the relationship between alpha modulation and social function. These results suggest that alpha modulation may offer a useful tool to understand phenotypic heterogeneity associated with sex differences in ASD.

337 **219.337** Initial Eye Gaze to Faces and Their Functional Consequence on Face Identification Abilities in Autism Spectrum Disorder

K. Schauder[1], *W. J. Park*[2], *Y. Tsank*[3], *M. P. Eckstein*[3], *D. Tadin*[4] *and L. Bennetto*[1], *(1)Clinical and Social Sciences in Psychology, University of Rochester,*

Rochester, NY, (2)University of Washington, Seattle, WA, (3)University of California Santa Barbara, Santa Barbara, CA, (4)Brain and Cognitive Science, University of Rochester, Rochester, NY

Background: Two areas of active research in autism spectrum disorder (ASD) include visual social attention and face processing. The visual social attention literature demonstrates that individuals with ASD exhibit decreased attention to salient social stimuli. Research on face processing suggests deficits in this domain in ASD, but includes many mixed findings regarding the nature and extent of these differences. The existing literature in these areas points to the need for additional research that carefully characterizes visual social attention to faces, optimizing precision in both the spatial and temporal domains, and assessing its functional role in a specific task or context (e.g., face identification). One way to achieve this is to focus on the most important, or critical moments, for a given context. Highly complex contexts, such as typical social interactions, are comprised of a series of critical moments that contain brief, specific, and often unpredictable cues. A simpler context, such as face identification, is also comprised of critical moments of processing. Specifically, the first moment one looks at a face has been shown to be highly informative and sufficient to identify faces in neurotypical adults.
Objectives: The current study focused on comprehensively characterizing the first moment one looks to a face and its functional consequence on face identification abilities in adolescents with and without ASD.

Methods: 42 adolescents with and without ASD (n = 21 per group) completed an adapted version of an established eye-tracking and face identification paradigm. Specifically, a series of faces were presented briefly, and we observed where participants naturally look first, while simultaneously measuring their face identification abilities. Then, the location at which individuals look when presented a face was experimentally manipulated, and we observed how face identification performance varied as a function of that location. Participants also completed the Dartmouth Face Perception Test (DFPT), a more traditional measure of face identification.

Results: Adolescents with ASD showed strikingly similar patterns of behavior related to initial eye gaze to faces (average first look location: t(40)=.61, p=.54; variability (SD) of landing location of the first look across trials: t(40)=-.32, p=.75) and face identification performance (t(40)=.60, p=.55) for briefly presented faces when naturally viewing faces. Face identification accuracy varied as a function of experimentally manipulated first look location (F(4,124)=26.77, p<.001), but there were no differences between groups (F(1,31)=.10, p=.75). Although there were no group differences related to first look, adolescents with ASD performed significantly worse on the DFPT compared to TD controls (t(40)=2.56, p=.01).

Conclusions: Results suggest that the initial look to faces and face identification for briefly presented faces are intact in ASD, ruling out the possibility that deficits in face perception, at least in adolescents with ASD, begin at the initial look. However, individuals with ASD showed impairments on the more traditional measure of face identification, pointing to the possibility that atypicalities in face processing in ASD appear after the first look.

338 **219.338** Intranasal Oxytocin Enhances Perceptual Mechanisms for Voice-Identity Recognition.

K. Borowiak[1,2,3] *and K. von Kriegstein*[2,3]*, (1)Berlin School of Mind and Brain, Humboldt University of Berlin, Berlin, Germany, (2)Technical University Dresden, Dresden, Germany, (3)Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany*

Background: Individuals with autism spectrum disorder (ASD) have difficulties recognizing other people by the voice – a deficit associated with reduced responses in the right posterior superior temporal sulcus/ gyrus (pSTS/STG) (Schelinski *et al.*, 2016, *SCAN*; Schelinski *et al.*, 2017, *Autism Res*). The right pSTS/STG has been implicated in the perceptual analysis of voice-identity information (Maguiness *et al.*, 2018, *Neuropsychologia*). Intranasal oxytocin can promote face recognition and modulate face-sensitive brain responses in ASD (Domes *et al.*, 2013, *Biol Psychiatry*; Guastella *et al.*, 2010, *Biol Psychiatry*).
Objectives: To investigate whether intranasal oxytocin can enhance the impaired voice-identity recognition and increase the right pSTS/STG responses in ASD.

Methods: Nineteen adults with ASD (ASD group) and nineteen typically developed (TD) controls (control group) participated in a randomized, double-blind, placebo-controlled, cross-over design study. The groups were pairwise matched on age, gender, handedness and intelligence quotient (IQ). All participants had normal hearing and were free of psychopharmacological medication. Participants with ASD had already received a formal clinical diagnosis of ASD (Asperger Syndrome/ childhood autism (1 male; verbal IQ = 109)) according to the diagnostic criteria of the International Classification of Diseases (ICD 10; World Health Organization, 2004). Within the study, they underwent additional clinical assessment using Autism Diagnostic Observation Schedule (ADOS, Lord *et al.*, 2000, *J Autism Dev Disord*) conducted by researches with formal training. Participants completed two sessions of a functional magnetic resonance imaging (fMRI) experiment on voice-identity recognition: after oxytocin and after placebo administration. The experiment included two conditions: voice-identity task and speech task. In both conditions, participants listened to blocks of neutral two-word sentences spoken by four male speakers. In the voice-identity task, participants matched the identity of each speaker to a target speaker. In the speech task, participants matched the content of each sentence to a target sentence. Targets were presented at the beginning of each block.
We calculated a three-way ANOVA: Substance (oxytocin, placebo) x Task (voice-identity, speech) x Group (ASD, control). Region of interest (ROI) was the right pSTS/STG, because it is known to show decreased BOLD response to voice-identity vs. speech recognition in ASD compared to TD controls (Schelinski *et al.*, 2016, *SCAN*).

Results: Oxytocin did not have any effect on the behavioral performance in the voice-identity recognition experiment. For the ROI, we found a significant three-way interaction Substance x Task x Group ($p < .05$ FWE corrected). Post hoc t-tests revealed that oxytocin increased right pSTS/STG responses to voice-identity vs. speech in the control group, but not in the ASD group.

Conclusions: Our results suggest that oxytocin can enhance perceptual analysis of voice-identity features in the right pSTS/STG in TD individuals. This was not the case in ASD, at least not to the same extent as in TD population, which supports previous evidence that perception of voice identity is atypical in ASD.

339 **219.339** Model-Based Approach Reveals Differences in Children's Cooperation during Social and Non-Social Exchange

N. Shah[1]*, C. Korn*[2]*, K. A. Pelphrey*[3] *and G. Rosenblau*[4]*, (1)Autism and Neurodevelopmental Disorders Institute, George Washington University and Children's National Health System, Washington, DC, (2)Institute for Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, (3)University of Virginia, Charlottesville, VA, (4)Yale University, New Haven, CT*

Background:
Cooperation is a complex and inherently social phenomenon, relying on our ability to learn about other humans and adapt to their strategies. In early childhood, humans become increasingly skilled collaborators as they develop more sophisticated models of other people's intentions and behaviors. In contrast, children with autism spectrum disorder (ASD) have core deficits in inferring others' mental states from subtle, implicit social cues that may significantly impair cooperation. Computational modelling, in particular Reinforcement learning (RL) algorithms, could reveal the mechanisms underlying cooperation in typically developing (TD) children and how these differ in children with ASD.

Objectives:

We use a computational modeling approach to characterize how TD children and children with ASD sustain cooperation with a peer (social) versus a computer partner (non-social). We hypothesize that cooperation strategies will differ between the social and non-social conditions in TD children; conversely, cooperative strategies will not differ between conditions in children with ASD.

Methods:

In two visits, children play child-friendly versions of the multi-round trust game (TG). In the TG, children have the option to either keep five coins or share any amount with their partner. Their partner receives four-times the amount of coins and can either keep everything or share half back. Children were unaware of the number of trials each game comprises.

In the initial visit, children (TD-group: N=37, age=13 years, SD=3.26) perform an IQ test and play a non-adaptive computer partner who shares 70% of the time (fixed non-social condition). In the second visit, children (TD-group: N=25, age=12 years, SD=2.6), are paired with a peer based on age, sex and IQ. Children do not know each other before the visit. They are told that they would sometimes play with the peer (social condition) and sometimes with a computer algorithm (adaptive non-social condition). In fact, they only play with their peer once.

Results:

During the fixed non-social condition, TD children share with the computer partner 61% of times on average. Children share similar amounts when knowing they play the adaptive non-social computer partner (59%). Compared to non-social conditions, children share more often when they think they play with the peer in the social condition (68%). Children are also more forgiving, re-initiating cooperation after the trustee defects, in the social condition compared to the computer conditions.

Bayesian model comparison shows that TD children's decisions to share in the non-social and social conditions rely on different strategies. In both non-social conditions, RL models best describe their behavior. Notably, in the social condition (that only differs in the information given to the child) a simpler tit-for-tat strategy describes children's behavior more accurately.

Conclusions:

Results indicate that a computational modeling approach can detect selective social strategies for establishing trust and cooperation in TD children. In a next step, we will test the how these strategies differ in children with ASD. Our approach could yield objective and quantifiable markers of cooperation in children with ASD that improve phenotypic classification of the disorder.

340 **219.340** Neural Correlates of Individual Facial Feature Processing in ASD

T. C. Parker[1], *G. Dawson*[2], *S. J. Webb*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Autism spectrum disorder (ASD) is a neurodevelopmental condition, characterized by difficulties in social communication alongside narrow interests, repetitive behaviors, and sensory sensitivities (American Psychiatric Association, 2013). Atypical neural responses to faces is thought to contribute to social deficits in ASD (Kang et al., 2018). Compared to typically developing (TD) controls, individuals with ASD exhibit delayed brain responses to upright faces at a face-sensitive event-related potential (ERP) known as the N170 (Bentin et al., 1996; McPartland et al., 2004). Yet, questions persist regarding how those with ASD respond to different classes of facial stimuli. Thus, investigating the physiology of the N170 to distinct facial percepts may provide additional insight on nature of atypical face perception in ASD and its relation to the clinical phenotype.
Objectives: To confirm previous findings that temporal processing of upright faces are delayed in individuals with ASD and examine differential response patterns for classes of facial stimuli across TD and ASD groups.

Methods: ERPs were recorded from 11 adolescents and adults with ASD (10 male and 1 female) and 21 TD controls (18 male and 3 female) using a 128-channel Geodesic Sensor Net. The sample was matched on age (ASD: M=22.44, SD=8.45; TD: M=25.57, SD=7.77) and IQ (ASD: M=101.82, SD=19.43; TD: M=112.81, SD=14.3051). Participants were presented with two stimulus blocks each composed of 240 gray-scale digital images on a computer monitor with a black background. The first block included eyes, upright faces, inverted faces, and distorted faces. The second block was composed of hands, noses, lips, and faces. The N170 was extracted from six electrodes over the right occipitotemporal scalp. Peak amplitude and latency were analyzed in response to eyes, upright faces, inverted faces, and distorted faces. Data analysis for N170 amplitude and latency in response to hand, nose, lips, and face stimuli is ongoing. ASD symptomology was measured using the Autism Diagnostic Interview-Revised (ADI-R) and DSM-IV clinical diagnosis was determined by the senior author.

Results: There was a significant main effect of condition on N170 latency ($F(3, 28)=9.135$, $p<0.001$) and N170 amplitude ($F(3, 28.00)=16.387$, $p<0.001$) across groups, with faster N170 components to eyes than upright faces, distorted faces, and inverted faces. Additionally, participants with ASD exhibited slower right N170 latency for upright faces than TD individuals (ASD: M=172.00, SD=24.27; TD: M=150.48, SD=26.09; $p=0.031$). However, no significant associations were found between groups in eyes, distorted face, and inverted face conditions.

Conclusions: Consistent with previous research, individuals with ASD exhibit longer N170 latencies to upright faces than TD individuals. Our findings also show that both groups display enhanced response to eye conditions, suggesting shared salience of eye stimuli. Comparable neural responses between groups for other stimuli suggests atypical neural responses to faces in ASD may depend on prototypic face configuration. Additional EEG research studying top-down face processing is needed to elucidate the relationship among holistic and configural face processing in ASD.

341 **219.341** Psychophysiological Processing of Emotions in Individuals Varying in Autistic Traits and Social Anxiety

***C. L. Dickter**, S. C. Taylor, B. Daugherty, E. Acors, N. Hoyt and J. Burk, College of William and Mary, Williamsburg, VA*

Background:
Individuals with autism spectrum disorder (ASD) exhibit differences in emotional processing compared to non-ASD individuals. Similarly, individuals with social anxiety disorder (SAD) also show differences in emotional processing than those without SAD. These processing differences are thought to be associated with differences in brain structures and in connectivity between brain regions related to face processing and social cognition. Because ASD and SAD are co-morbid conditions, examining how traits related to ASD and SAD uniquely predict the neural processing of emotional stimuli can help to disambiguate the shared and distinct contributions that traits related to these two conditions can have on emotion processing.

Objectives:

This study aimed to evaluate differences in emotional face processing based on varying degrees of self-reported autistic behaviors and social anxiety. Event-related potentials (ERPs) were used to assess early neural processing directed at emotional faces with the goal of examining the distinct relationships between traits related to autism and social anxiety and the neural processing of specific emotions.

Methods:

Fifty-three individuals (26 males; M_{age} = 19.88 years) completed an oddball task in which participants identified a face depicting an emotional expression amongst a series of faces displaying neutral expressions. Participants completed two blocks of 300 trials consisting of mostly neutral faces with 15% oddball pictures displaying emotions (i.e., happy, angry, surprise, and fear). Each face was presented for 1000ms with an intertrial interval between 1000-1500ms. Participants pressed a key as quickly as possible when they identified a face depicting an emotion. In addition, participants completed the Autism Quotient Scale (AQ) and the Social Phobia and Anxiety Inventory (SPAI-23). EEG activity was recorded and ERPs were quantified between 50 and 150ms at parietal electrodes (P1), between 150 and 250ms at parietal electrodes (P2), between 175 and 350ms at frontal electrodes (N2), and between 300 and 650ms at parietal electrodes (P3); see Figure 1.

Results:

The SPAI was correlated with P1 amplitude to happy faces, r = .58, p = .040, N2 amplitude to fearful faces, r = .54, p = .048, and P3 amplitude to angry faces, r = .48, p = .033. Scores on the SPAI (M = 20.90, SD = 9.87) and AQ (M = 16.89, SD = 8.66) were significantly correlated with one another, r = .42, p = .017. In order to assess the distinct contribution of SPAI controlling for AQ, regression analyses were performed. Results revealed that P3 amplitudes to angry faces were significantly predicted by the SPAI, β = .629, p = .040, when controlling for AQ, as demonstrated in Figure 2. For the other analyses, controlling for AQ reduced the effect of the SPAI on ERP amplitude.

Conclusions:

Together, these findings indicate that social anxiety traits distinctly predict the neural processing of certain emotions when controlling for autistic traits. These findings may contribute to our understanding of the social cognitive processes underlying the impaired identification and interpretation of emotional facial expressions in socially anxious and autistic individuals, which is crucial for developing successful interpersonal communication interventions.

342 **219.342** Reduced Neural Processing of Speech-in-Noise in the Left Inferior Frontal Gyrus in Autism Spectrum Disorder

***S. Schelinski**[1,2] and K. von Kriegstein[1,2], (1)Technische Universität Dresden, Dresden, Germany, (2)Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany*

Background: Recognising what another person is saying under noisy conditions (i.e. speech-in-noise perception) is an everyday challenging experience. There is evidence that speech-in-noise recognition is restricted in people with an autism spectrum disorder (ASD) (Alcantara et al., 2004; Schelinski & von Kriegstein, in prep.). However, the underlying neuronal mechanisms of this speech perception difficulty are unclear. A recent meta-analysis showed that three cerebral cortex regions are particularly involved in speech-in-noise processing (Alain et al., 2018).
Objectives: Here we tested, whether atypical responses in these regions might explain speech-in-noise perception difficulties in ASD.

Methods: 17 adults with ASD (M_{age} = 30,53 years; 14 males) and 17 typically developing adults (matched pairwise on age, sex, handedness, and full-scale intelligence quotient (IQ)) performed an auditory-only speech recognition task during functional magnetic resonance imaging (fMRI). All participants had normal hearing (confirmed with pure tone audiometry) and did not take psychotropic medication. Participants in the ASD group had previously received a formal clinical diagnosis and underwent additional clinical assessment including the ADOS (Lord et al., 2000) and ADI-R (Lord et al., 1994). During the fMRI experiment, we presented blocks of sentences that were either presented with or without noise (noise / no noise condition). Sentences were semantically neutral and phonologically and syntactically homogenous. In the noise condition, sentences were presented together with pink noise (signal-to-noise ratio = -8). In both conditions, the first sentence of a block was the target sentence and participants decided whether the content of the following sentences matched the content of the target sentence. Both conditions included the same set of sentences. All sentences were spoken by six male speakers. Before the fMRI session, participants were familiarised with the voices of all speakers together with their face during an audio-visual training phase. For the fMRI analysis we used a general linear model implemented in SPM12.

Results: Both groups showed typical speech-sensitive blood-oxygenation-level-dependent (BOLD) responses for the no noise condition including bilateral superior temporal sulcus, precentral and inferior frontal brain regions (p < .05 family wise error (FWE) corrected for the whole brain). For recognising speech in the noise as compared to the no noise condition we found higher BOLD responses in the control as compared to the ASD group in the left inferior frontal gyrus (left IFG), whereas both groups showed similar responses for the two other regions that are particularly involved in speech-in-noise processing (i.e. right insula and left inferior parietal lobule; p < .05 FWE corrected for the three regions of interest). An ANOVA revealed that there were no significant group differences in the speech recognition performances for none of the conditions (for p < .05). The ASD and the control group did not differ significantly in the average amount of head movements (for p < .05).

Conclusions: Our findings suggested that in ASD the processing of speech is particularly reduced in the left IFG under noisy conditions. These differences might be important in explaining restricted speech comprehension in noisy environments in ASD.

343 **219.343** Relationships between Self-Reported Social Reward and Neural Response to Peer Interaction in Children with Autism Spectrum Disorder and Typical Development

K. A. McNaughton[1], *D. Moraczewski*[1], *L. A. Kirby*[2], *H. A. Yarger*[3], *K. R. Warnell*[4], *A. Cechaviciute*[3] *and E. Redcay*[5], *(1)Neuroscience and Cognitive Science Program, University of Maryland, College Park, MD, (2)Yale Child Study Center, New Haven, CT, (3)University of Maryland, College Park, MD, (4)Department of Psychology, Texas State University, San Marcos, TX, (5)Department of Psychology, University of Maryland, College Park, MD*

Background: The social motivation hypothesis proposes that individuals with autism spectrum disorder (ASD) have reduced motivation to engage in social interactions compared to children with typical development (TD). However, neuroimaging and behavioral support for this hypothesis is mixed. These inconsistent results could be a relic of neuroscience paradigms typically used to assess social reward, which rely on static images rather than the social reward experienced in a real-time interaction with a peer.

Objectives: To assess the relationship between self-reported enjoyment of social interaction and the neural response of a reward network brain region, the ventral striatum, to a real-time peer interaction in children with TD and ASD.

Methods: Children with ASD (*n*=26, 2 female, 7-15 years old) and TD (*n*=26, 2 female, 8-14 years old) engaged in a social chat paradigm while their brain activity was measured using functional magnetic resonance imaging. Groups did not differ on age or full scale IQ (*p*s>0.10). In the chat paradigm, participants sent messages about their interests to a perceived peer or computer. Participants then received messages back indicating engagement or disengagement from the peer ("Me too"/ "I'm away") or computer ("Matched"/ "Disconnected"). Ventral striatum response to computer engagement was subtracted from ventral striatum response to peer engagement to create a metric of neural response to social engagement with a peer. This difference score was correlated with the Admiration subscale of the Social Reward Questionnaire (SRQ), measuring trait level enjoyment in receiving others' approval, as well as children's self-reported enjoyment of engaging with the peer minus enjoyment of engaging with the computer after the paradigm.

Results: Children with TD and ASD did not differ in their self-report of enjoyment of interacting with the peer compared to the computer ($t(50)=-0.60$, $p>0.10$) or in their self-report of enjoyment in receiving others' approval (SRQ-Admiration; $t(39)=-0.52$, $p>0.10$). However, the relationship between these two measures of self-reported enjoyment of social reward and ventral striatum response to peer engagement differed between the two diagnostic groups. Increased enjoyment in the peer interaction compared to the computer interaction was associated with increased ventral striatum response to peer compared to computer in children with TD ($r(24)=0.57$, $p<0.01$), but not children with ASD ($r(24)=-0.002$, $p>0.10$). These correlations significantly differed from each other ($p<0.05$). In contrast, decreased enjoyment in others' approval (SRQ-Admiration) was associated with increased ventral striatum response in children with ASD ($r(21)=-0.35$, $p<0.10$), while there was a non-significant association in the opposite direction in children with TD ($r(16)=0.34$, $p>0.10$). Again, these correlations significantly differed from each other ($p<0.05$).

Conclusions: The relationship between self-reported social reward and neural response to real-time peer interaction differs between children with TD and ASD. While increased self-reported social reward was associated with increased activation of a reward network brain region in children with TD, the opposite relationship was present in children with ASD. These findings highlight the importance of more thoroughly characterizing the neural correlates of social reward in children with ASD within ecologically valid contexts and determining their relevance to real-world social interactions.

344 **219.344** Social Learning Relies on Distinct Cognitive Mechanisms in Adolescents with and without Autism

G. Rosenblau[1,2], *C. Korn*[3], *A. Dutton*[1], *D. Lee*[1] *and K. A. Pelphrey*[4], *(1)Yale University, New Haven, CT, (2)George Washington University, Washington DC, DC, (3)Institute for Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, (4)University of Virginia, Charlottesville, VA*

Background:

Many of our efforts in social interactions are dedicated to learning about other persons' preferences, mental states, and behaviors—abilities referred to as Theory of Mind (ToM). ToM abilities continue to develop throughout adolescence and are associated with positive peer relationships and emotional wellbeing. Adolescents with ASD have core deficits in ToM, which have been a main focus in social skill trainings and interventions for this age group. Despite the large body of research specifying ToM deficits and intervention outcomes of adolescents with ASD, a mechanistic understanding of how individuals integrate environmental cues to learn about others is lacking.

Objectives:

Here we aim at revealing the cognitive mechanisms underlying learning about others' preferences in adolescents with ASD using a computational modeling approach. In a next step, we will explore the neural implementation of these cognitive mechanisms.

Methods:

We devised a novel preference task, in which TD adolescents (N=23), and adolescents with ASD (N=21) rated how much three peers liked a variety of items (e.g. activities, fashion items and food) in the scanner. After each rating, they received feedback about the peer's preference ratings. Participants could improve predictions about a new item by integrating feedback about similar past items into their judgements. After this learning task, participants rated their own preferences for the same items outside the scanner.

The preference profiles used in the learning task were of real adolescents who participated in an online preference survey. In total, we obtained 103 preference profiles. Three profiles were selected for the learning task and the remaining 100 were used to compute learning priors (e.g. an individual's prior knowledge about their peers' preferences).

Results:

Prediction errors, the difference between participants' judgements and the trial-by-trial feedback, did not differ between groups. To test finer-grained group differences in learning strategies, we devised various computational models: non-learning regression models and reinforcement learning (RL) models. RL models describe participants' judgements over time based on previous feedback alone, or based on a combination of feedback and either own preferences or priors. We also tested more sophisticated models, which assume that participants represent similarities between item preferences for their peer group (e.g., participants know that preferences often are similar for apples and pears but not necessarily so for apples and kale). Prediction errors are then scaled according to these fine-grained similarities between the items (similarity-RL model). Bayesian model comparison revealed that preference ratings of TD adolescents relied on a combination of similarity-RL and participants' own preferences. In contrast, preferences of ASD adolescents were best described by a non-learning model that relied on simple priors (i.e. peers' average preference ratings) for each item.

Conclusions:

We show that computational models are well suited to differentiate between social learning strategies of TD and ASD samples. In a next step, we will explore how parameters derived from the winning model for either group are implemented in brain activity. This will provide biological validity for the models and help specify differences in the underlying neural mechanisms of social learning in adolescents with ASD.

345 **219.345** Visual Scanning Patterns of School-Age Children Completing an Adapted Reading the Mind in the Eyes Test

Z. Arnold[1], *J. M. Moriuchi*[1], *E. T. Crehan*[2], *E. V. Ocampo*[1] *and L. Soorya*[1], *(1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA*

Background: Impairments in mentalizing represent a key deficit in social cognition for children with autism spectrum disorder (ASD). Explicit measures of mentalizing abilities, such as the Reading the Mind in the Eyes Test (RMET), generally show between-group differences with lower performance in individuals with ASD compared to typically-developing controls. However, some individuals with ASD do achieve high accuracy on explicit mentalizing measures, often representing a discrepancy from continued difficulty in applying mentalizing skills within everyday social contexts. One hypothesis is that individuals with ASD may utilize compensatory strategies, such as relying on verbal reasoning skills, to solve mentalizing problems in a different way than typically-developing peers. To help understand the underlying mechanisms of children's mentalizing performance, we developed a computer-based version of the RMET co-registered with eye-tracking. By examining visual scanning patterns as participants completed the RMET, we were able to measure not just whether individuals were accurate in social attributions, but also how individuals were attempting to make social attributions on a moment-by-moment basis.

Objectives: The aims of the current study were (1) to compare performance on a computerized version of the RMET to autism severity metrics and (2) to identify visual scanning patterns predictive of RMET performance and severity of autism symptomatology.

Methods: Participants included 17 children with ASD (15 male, 2 female) between the ages of 8 and 11 years old. Children were verbally fluent (Full Scale IQ: mean=100.7 [17.5]) and represented a broad range of level of social disability (ADOS-2 Calibrated Severity Score: mean=6.9 [2.4], range=1 to 10). Participants were enrolled in a randomized clinical trial of a combination behavioral-pharmacological treatment targeting social cognition and social behavior; the current study focuses only on data at baseline, pre-treatment.

Eye-tracking data were collected while participants completed an adapted, computerized version of the child RMET (Figure 1). Percentage of visual fixation time on the eyes image and on word response options was calculated for each child. In addition, visual scanning patterns were evaluated using more temporally- and spatially-sensitive measures of saccade frequency and directionality.

Results: Performance on the RMET ranged from 25 to 90% correct responses. Greater accuracy on the RMET was correlated with reduced autism symptomatology as assessed both by clinician rating on the ADOS-2 ($r=-0.66$, $p<0.005$) and parent rating on the SRS-2 ($r=-0.52$, $p<0.05$). RMET performance was also positively correlated with higher cognitive functioning ($r=0.56$, $p<0.05$). Participants who exhibited higher visual attention to the eyes image of RMET stimuli and lower visual attention to word response options tended to have less severe symptomatology (eyes: $r=0.62$, $p<0.05$, words: $r=-0.53$, $p<0.05$). There was no significant relationship between visual attention measures and cognitive functioning. Ongoing analyses are examining visual scanning patterns that may mediate the relationship between cognitive functioning and RMET performance.

Conclusions: The adapted, computerized RMET yielded a broad range of mentalizing performance and was predictive of social functioning in our pilot sample of school-age children with ASD. By evaluating both mentalizing accuracy and underlying mechanisms, this new approach holds promise as a more sensitive measure of social cognition.

9:00 Transcending Barriers to Development of Targeted Treatments for Fragile X Syndrome

E. Berry-Kravis*, Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL*

Despite extensive molecular, cellular and animal model data supporting disease pathway-targeted treatments in fragile X syndrome, initial clinical trials based on FDA precedents failed to show benefit for behavior in adult and adolescent humans with FXS. Rethinking of translational models and drug development strategies based on this experience has revealed gaps in understanding of optimal age of treatment, trial designs, need for better outcome measures and biomarkers that assay core aspects of the disease, and potential need to measure drug effects in the setting of a learning paradigm. Work has been done to address these issues and this process has informed design of more recent FXS trials, including novel trial designs in progress to show disease modification in terms of learning and functional improvements. Lessons learned in FXS trials and new designs developed for FXS can inform design of trials of targeted treatments for other single gene models of ASD, and for idiopathic ASD.

Biomarkers (molecular, phenotypic, neurophysiological, etc)
227 - Novel Imaging Approaches to Biomarker Discovery in Autism Spectrum Disorder: Recent Findings from the Pond and EU-AIMS Networks
10:30 AM - 12:30 PM - Room: 517C

Panel Chair: Eva Loth, *Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Over recent years, precision medicine has become a key focus of autism research. The aim is to combine new pathophysiologically based therapies with stratification biomarkers to predict which therapy may be beneficial for a particular autistic person. This approach chiefly relies on new 'translatable' methods that help linking findings from animal models to humans, and new methods to make predictions of individuals and to identify subgroups. Here we present several novel, complementary approaches adopted in two international autism consortia – the POND Network and EU-AIMS/ AIMS-2-TRIALS. Both consortia include multi-disciplinary preclinical and large-scale clinical programmes. In this panel, we will be sharing innovative new methods, ideas and data to advance biomarker discoveries and validation, and increase robustness and replication of findings.

10:30 **227.001** Animal Population Imaging - Linking Molecular Pathways to Autism Clusters in the Mouse Using the Neuroanatomy.

J. Ellegood[1], *Y. Yee*[1,2], *L. R. Qiu*[1], *B. C. Darwin*[1], *R. M. Henkelman*[1,2] *and J. P. Lerch*[1,2], *(1)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (2)Medical Biophysics, University of Toronto, Toronto, ON, Canada*

Background: Autism is extremely heterogeneous, not just in behaviour, but also in genetics, and neuroanatomy. Over the past 10 years, we have established a magnetic resonance imaging (MRI) database of mouse models related to autism, which allows the investigation of the neuroanatomy in a large autism population in the mouse. Addtionally, this dataset provides us with a metric by which we can cluster these models and examine commonalities and differences between them in the hope of subcategorizing autism.
Objectives: The purpose here is twofold. 1) To further our previous work, which examined 26 different mouse models of autism (Ellegood et al. 2015), in an effort to characterize and cluster our current dataset of 92 different mouse models, and 2) to look for existing molecular pathways which may explain these clusters.

Methods: The data used in this study was collected from 92 different autism related mouselines and includes over 3,700 mice. Imaging was performed ex-vivo using a 7T MRI with a T2 weighted, 3D fast spin echo sequence which acquires data at an isotropic resolution of 40 µm (Spencer Noakes et al. 2017).

Data Analysis – To visualize and compare any differences, the images are registered together (Lerch et al., 2011). From this the volumes of 182 different regions (Dorr et al. 2008, Ullmann et al. 2013, and Steadman et al. 2014, Richards et al. 2011, Qiu et al. 2018, Beera et al. 2017) were calculated. Group differences in each of the 182 regions across the different mouse models were calculated (measured as effect size) and used to group the different models using hierarchical clustering algorithms.

Bioinformatics – Online databases, including StringDB (string-db.org), the Molecular Signatures Database (software.broadinstitute.org/gsea /msigdb) and the KEGG Database (www.genome.jp/kegg), were used to link specific molecular pathways to our clusters to provide more information about potential common determinants that underlie the models.

Results: Our data suggests that the autistic phenotype both preferentially affects key regions of the brain, but also divides the autism neuroanatomical phenotype based on directionality and localization of the differences throughout the brain. In total, four different clusters were found from the 92 different models. Additionally, what appears to link these clusters together, outside of the neuroanatomy, is a shared molecular pathway. The first cluster, which includes the models Chd8 and Dvl1, links significantly to the Wnt signaling pathway. The second cluster, which includes the models Arid1b and Tsc1, links to MapK and mTor signaling pathways. The third cluster, which includes the models Nlgn1, Nlgn3, Nrxn1, and Shank3, links to cell adhesion. The final cluster does not link significantly to any specific pathway, which may indicate the need for further refinement of our clusters.

Conclusions: The heterogeneity of autism is problematic. Therefore, finding ways to link autism models or genetic modifications together can be very powerful. The hope with techniques such as this is ultimately to subcategorize and increase the diagnostic specificity of autism.

10:55 **227.002** Sex Difference in Structural Hemispheric Asymmetry in ASD

D. L. Floris[1], *T. Wolfers*[2], *M. Zwiers*[2], *L. G. EU-AIMS*[3], *J. K. Buitelaar*[4] *and C. B. Beckmann*[5], *(1)Donders Centre for Cognitive Neuroimaging, Nijmegen, Netherlands, (2)Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands, (3)EU-AIMS Organization, London, United Kingdom, (4)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (5)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom*

Background: Autism spectrum disorder (ASD) is characterized by a striking male preponderance with three times more males being affected than females. While neuroimaging studies have started to pick up on studying sex differences in ASD, none has addressed the question of sex differences with respect to hemispheric specialization. ASD is characterized by a disruption of specialization in the brain with findings pointing to atypical hemispheric asymmetry across hemispheres (Herbert et al., 2002; Floris et al., 2016). Sex differences in hemispheric specialization have frequently been reported in neurotypical (NT) individuals with males showing more pronounced patterns of lateralization than females, however, no study has addressed this question in ASD.
Objectives:

We aimed to explore sex differences in hemispheric lateralization across individuals with ASD and NT controls.

Methods:

We selected high quality structural T1-weighted MRI data from the Longitudinal European Autism Project dataset including 94 females with ASD aged 6-30 years, 260 IQ-and age-matched males with ASD as well as 166 age-matched NT males and 90 NT females. T1-weighted images were preprocessed using SPM12 and the CAT12 toolbox. Specific preprocessing steps were adopted to meet requirements for the analysis of asymmetry: 1) images were segmented using a symmetric tissue probability map; 2) segmented images were flipped along the x-axis; 3) original (OI) and flipped images (FI) were used to create a symmetric DARTEL template and subsequently registered to it; 4) laterality indices was calculated at each voxel by the formula:(OI–FI)/(OI+FI)*2. Laterality images were restricted to the right hemisphere (RH) and smoothed with a 4mm FWHM kernel. Main effects and interactions were tested by regression of a GLM at each voxel with group and sex as fixed factors and age and scanning sites as nuisance covariates. Significance levels for clusters were set at a voxel-level cluster-forming $p<0.001$ and by their number of expected voxels (spatial extent threshold) according to Gaussian Random Field theory. Statistical outcomes were corrected for multiple comparisons at the cluster-level by controlling the topological false discovery rate (FDR) at $q<0.05$. Significant results were correlated with symptom measures such as

the ADOS and ADI.

Results:

Voxel-wise analysis of laterality in the RH revealed significant group-by-sex-interactions in the posterior cingulate cortex and the pars trinagularis. Males with ASD showed reduced leftward asymmetry compared to NT males, while ASD females showed increased leftward asymmetry compared to NT females. The opposite pattern was evident in the angular gyrus and supplementary motor area with ASD females showing reversed rightward asymmetry compared to NT females and ASD males showing reversed leftward asymmetry compared to NT males. Results remained the same when including handedness and FIQ as nuisance covariates. Correlation analyses with ADI- and ADOS-subscales did not yield any significant results.

Conclusions:

Males and females with ASD exhibit differential patterns of structural hemispheric lateralisation compared to NT controls in language processing regions and default network hubs. While males with ASD show patterns that resemble those in NT females, females with ASD exhibit neural masculinization suggesting that models of 'gender-incoherence' of ASD also apply to atypical hemispheric lateralization.

11:20 **227.003** Using Canonical Correlation Analysis Approaches to Develop a Circuit-Based Clinical Measure of Autism Core and Associated Symptoms

Background:

Key challenges for clinical trials of autism include the clinical and etiological heterogeneity of the condition, and the lack of sensitive outcome measures. Existing clinical measures typically assess a collection of autism-related clinical symptoms. However, it is likely that various behavioural symptoms – even within specific domains – may have different neurocognitive or neurobiological underpinnings. Moreover, due to the diversity of autism the *same* behavioural symptom may result from different neurobiological abnormalities in *different autistic individuals*. Therefore, purely behaviourally-defined measures that encompass various neurobiological processes may not be sufficiently sensitive to detect treatment effects. Here we adopt a novel approach starting with robustly defined brain circuits that underpin fundamental social, emotional, motivational, and cognitive processes, and then mapping brain-behaviour relationships to different subgroups.

Objectives: To create a "circuit-based clinical outcome measure" we used Canonical Correlation Analysis (CCA) based approaches to identify items from existing clinical measures that best covary with brain function in robust, pre-defined brain circuits, and explored whether these brain-behaviour relationships vary between different autism subgroups

Methods:

Combined clinical-fMRI data sets were available from ~100-300 autistic individuals and 80-220 control participants from the EU-AIMS Longitudinal European Autism Project. We used two CCA-based methods that allow us to identify relationships between two multivariate datasets (here clinical items and fMRI regions-of-interests) using information from cross-covariance matrices and that employ internal cross-validation mechanisms to enhance the robustness of the fitting. Regularised CCA can handle more samples than participants when required and maximise the correlation between clinical items and brain regions. To estimate the robustness of the canonical scores we used bootstrapping to generate clinical and imaging variable loadings on a subset of participants and then used these variable loadings to calculate median values of the estimated canonical scores on the excluded subset.

Canonical Vector Regression (CVR) uses variable loadings from CCA to obtain a regression fit to group membership (TD/ASD). We then entered individual scores from both methods into a cluster analysis using fuzzy c means and affinity propagation-based clustering with bootstrap estimation of the optimal cluster number. By combining CVR and RCCA we simultaneously separated individuals on two complementary aspects of the data - maximal correlation between brain and clinical symptoms and maximal distance between groups.

Results:

Preliminary analyses revealed robust correlations between network function and clinical symptoms between autism 'subgroups'. For example, RCCA and CVR between the Strength and Difficulties Questionnaire (SDQ) and ROIs in a reward task showed significant correlations in the first canonical variate (RCCA p=.001, CVR p=.024). 4 items significantly covaried with changes in ROIs; while ventral striatal activity in two conditions significantly covaried with changes in SDQ.

We found four observed clusters; two of which largely separated an ASD-subgroup from controls (Fig 1a) and maintained high predictive accuracy based on the predicted output (Fig 2).

Conclusions:

These CCA-approaches can identify clinical items that differentially covary with network function in ASD "subgroups". Next, we will sort clinical items according to network function across four fundamental bio-behavioural domains, and 'harmonise' them in terms of response format.

11:45 **227.004** Regression Clustering for Discovering Multiple Types of Brain-Behaviour Associations in a Sample: Data from the Pond Network

*S. Panahandeh[1], E. Anagnostou[2], J. P. Lerch[3] and **A. Kushki**[4], (1)Institute of Biomaterials and Biomedical Engineering, University of Toronto, Vaughan, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (4)Bloorview Research Institute, Toronto, ON, Canada*

Background: The autism spectrum is associated with significant heterogeneity in etiology, biology, and phenotype. This heterogeneity challenges traditional statistical tools used for examining brain-behaviour associations (e.g., linear regression), which do not take into account the possible presence of subgroups that can be characterized by different regression models. To address this challenge, we propose a novel data-driven and unsupervised approach to discover multiple types of brain-behaviour associations in a sample. This approach clusters the sample data into K groups, each with its own linear regression function. The difference between this method and traditional clustering is that the proposed approach groups data points based on their relative similarly to a regression line, not direct similarity to each other.

Objectives: Our objective was to discover multiple regression lines that explain the association of brain-phenotype patterns in ASD. Specifically, we looked at associations between cortical thickness and social communication function quantified using the Social Communication Questionnaire.

Methods: Data from a sample of 121 participants with a diagnosis of ASD were obtained from the POND Network (age:11.9(3.6); 98 male). Brain data included cortical thickness measurements from 76 regions of the brain obtained using the CIVET pipeline, corrected for total gray matter volume, sex, age, and scanner. Behavioural data were scores on the social communication domain of the SCQ. Analyses were performed using a machine learning pipeline which employs regression clustering to clusters the sample data into K groups that are characterized by different regression functions. To ensure stability of the found patterns, the analyses were run on 100,000 random partitions of the data, each including 5% of the participants. Th RANSAC algorithm was used to fit linear models to each subset of the data, and similarity matrices were built based on whether or not data points were on the same regression line. Spectral clustering was used to cluster the similarity matrices. Number of clusters was chosen to maximize the within-to-between scatter ratio. Clusters were validated by ensuring that the scatter ratios were significantly different than those for randomly generated data.

Results: Our results support the notion that SCQ-cortical thickness association can be characterized using multiple regression lines for several cortical regions previously implicated in ASD. These included the orbital part of the right superior frontal gyrus (2 clusters; regression slopes -3.5(0.2) and 10.7(0.4); p<0.00001) and the right posterior cingulate gyrus (2 clusters; regression slopes -4.6(0.2) and -3.7(0.3) ; p<0.00001). These results are shown in Figure 1. As seen in this figure, 2 clusters of points that lie on the same regression line are identified for each regions.

Conclusions: Our results demonstrate the feasibility of using data-driven approaches to model heterogeneity in brain-behaviour associations.

Panel Session
Biomarkers (molecular, phenotypic, neurophysiological, etc)
228 - Autism Spectrum in Tuberous Sclerosis Complex (TSC): Using Biomarkers to Connect Preclinical Models to Early Intervention
10:30 AM - 12:30 PM - Room: 518

Panel Chair: Darcy Krueger, *Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Autism spectrum disorder (ASD) and intellectual disability (ID) are severe neurodevelopmental conditions with early childhood onset and considerable clinical overlap. Able to be diagnosed at birth and with high penetrance of both ASD and ID, Tuberous Sclerosis Complex (TSC) provides unique opportunity for characterizing the earliest stages of ASD with and without coexisting ID. A comprehensive strategy spanning preclinical and clinical studies is being pursued in TSC to develop imaging and electrophysiologic biomarkers that predict ASD/ID risk and gain insight into the underlying structural and functional changes associated with the earliest stages of ASD and ID. The learning objectives of this panel are to (1) understand the phenotypic features of ASD and ID in TSC throughout the lifespan; (2) appreciate the challenges in ASD and ID assessment and treatment (including both pharmacologic and non-pharmacologic interventions) at young ages in high-risk populations such as TSC; and (3) review the latest progress in both animal models and human studies of TSC to develop imaging and electrophysiologic biomarkers that predict disease risk and assess treatment response in early ASD and ID.

10:30 **228.001** Behavioral and Developmental Characteristics of Infants and Young Children with Tuberous Sclerosis Complex (TSC)

J. Capal[1], *D. S. Murray[2], A. W. Byars[1], N. Bing[1], B. Kent[1], L. A. Bucher[3], M. E. Williams[4], S. E. O'Kelley[5], D. A. Pearson[6], M. Sahin[7] and D. A. Krueger[1], (1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (2)Autism Speaks, Boston, MA, (3)Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Univ. of Southern California/Children's Hosp. of Los Angeles, Los Angeles, CA, (5)University of Alabama at Birmingham, Birmingham, AL, (6)McGovern Medical School, Univ. TX Health Sci Cntr-Houston, Houston, TX, (7)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Autism spectrum disorder (ASD) has been reported in approximately 50% of individuals with Tuberous Sclerosis Complex (TSC). The severity and underlying causes of ASD are complex and highly variable, which presents a major barrier to identifying at-risk infants. In addition, many young children with TSC present with neurodevelopmental comorbidities including developmental delay and seizures, that make the diagnosis of ASD difficult.

Objectives: Describe behavioral and developmental characteristics of young children with TSC who have been evaluated by developmental and autism-specific assessments.

Methods: Children ages 0-36 months with TSC participated in the TSC Autism Center of Excellence Network, a large, multicenter, prospective observational study evaluating natural history of ASD in TSC. Children were evaluated longitudinally with Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales, 2ndEdition, Survey Interview (VABS-II), and Preschool Language Scales, 5thEdition (PLS-5). Autism-specific assessments, including the Autism Observation Scale for Infants (AOSI) administered at 12 months, and Autism Diagnostic Observation Schedule-Second Edition (ADOS-2) and Autism Diagnostic Interview-Revised (ADI-R), were administered at 24 and 36 months at which point a diagnosis of ASD or not ASD was assigned by expert clinical team. Multiple analyses were performed including utility of using the AOSI to predict positive ADOS-2 at 24 and 36 months determining differences in diagnostic ASD categories (ADOS-2 negative/ASD diagnosis negative (non-ASD)), ADOS-2 positive/clinical ASD diagnosis negative (Mixed), and ADOS-2 positive/ASD diagnosis positive (ASD) groups).

Results: As expected, the ASD group exhibited lower scores on all measures compared to the non-ASD group (p<0.01). The mixed group (N=23)

exhibited lower scores on nearly all measures of the MSEL, VABS-II, and PLS-5 compared to the non-ASD group (N=55) and higher scores for most of the same when compared to the ASD group (N=19) (p<0.05). Percentage-wise, 100% children in the ASD group at 24 months were developmentally delayed (SS<85 on the MSEL Early Learning Composite) compared to 70% in the mixed group and 44% in the non-ASD group. At 36 months, the mixed group (N=8) was more similar to the non-ASD group (N=35) than the ASD group (N=15)(p<0.05). The mean AOSI total score in patients diagnosed with ASD at 24 months was 13.3 ±6.7 versus 7.5 ±6.0 in patients not diagnosed with ASD (p=0.007). At 36 months, mean AOSI total score continued to be predictive of clinical diagnosis of ASD (12.4 ± 7.2 vs 7.1 ±4.3, p=0.032).

Conclusions: Autism specific characteristics may be present in young children with TSC that can be identified at 12 months by the AOSI. In addition, autistic traits are present in children with TSC that do not meet full criteria for ASD. This third group may represent a broader autism phenotype in TSC.

10:55 **228.002** Translatable EEG Measures in Mouse Models of Tuberous Sclerosis Complex (TSC)

M. E. Modi[1], *S. Gurnani*[1], *E. Bainbridge*[1], *S. Dhamne*[1], *B. Tracey*[2], *A. Rotenberg*[3] *and M. Sahin*[4], *(1)Neurology, Boston Children's Hospital, Boston, MA, (2)Electrical and Computer Engineering, Tufts University, Boston, MA, (3)Neurology, Harvard Medical School, Boston, MA, (4)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Tuberous sclerosis complex (TSC) is a rare genetic disorder associated with autism spectrum disorder (ASD) and epilepsy. Dysregulation of the mTOR pathway in TSC results in a loss of white matter integrity evident in imaging of patients, which is thought to be caused by alterations in axon outgrowth and synapse formation seen in animal and cellular models of Tsc1/Tsc2 mutation. Critical to harnessing the translational potential of animal models for drug discovery is the development of biomarkers that can be measured in both people and animals with high fidelity. The consequences of white matter disruption can be explored at the systems level in both animal models and patients through the measurement of neural activity via electroencephalography (EEG) to identify signatures of impairment associated with specific behavioral phenotypes and in response to pharmacological intervention.
Objectives: To identify translationally conserved alterations in neural activity associated with TSC related mutations, we characterized EEG based measures in transgenic mouse models of TSC that could be analogously measured in the patient population.

Methods: Utilizing mouse lines expressing a hypomorphic *Tsc2* allele or a restricted *Tsc1* mutation associated with selective social deficits, chronic *in vivo*EEG was recorded under baseline conditions and after either acute or chronic treatment with an mTOR inhibitor. Spectral features and seizure activity were characterized longitudinally over development and auditory evoked potentials elicited from auditory gating and mismatch negativity paradigms were extracted in adulthood.

Results: Mice with reduced expression of *Tsc2* have lower oscillatory power in low frequency bands (theta) but an increase in power in the high frequency bands (beta and gamma), which evolves over development. The changes in spectral power are associated with a progressive seizure phenotype that ultimately results in the premature death of the animals. Paradoxically, chronic treatment with an mTOR inhibitor reduces the seizure burden of the animals but exacerbates the spectral phenotype. Mutant animals also have alterations in the evoked response to auditory tones, relative to control animals, characterized by enhanced early components and diminished late components of the response waveform that are analogous to the responses seen in the patient population. Changes in spectral power and auditory evoked potentials are induced with chronic but not acute rapamycin treatment that parallel functional rescue.

Conclusions: Features of resting state EEG and auditory evoked potentials in TSC mouse models both recapitulate early findings in patients with TSC and are responsive to treatment with mTOR inhibitors. Upon validation, these features could be used to drive biomarker selection for ongoing clinical trials with mTOR inhibitors in TSC. More broadly, the conservation of neurophysiological phenotypes across animal models and patient populations in TSC supports the use of EEG as a translational modality for exploring neural deficits associated with connectivity and synaptopathy.

11:20 **228.003** Electrophysiological Biomarkers of ASD and Cognitive Impairment in Infants with Tuberous Sclerosis Complex (TSC)

S. Jeste[1], *A. H. Dickinson*[1], *K. J. Varcin*[2] *and C. A. Nelson*[3], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Telethon Kids Institute, Perth, WA, Australia, (3)Boston Children's Hospital, Boston, MA*

Background: Tuberous sclerosis complex (TSC) is an autosomal-dominant genetic syndrome highly penetrant for neurodevelopmental disorders, with estimates of ASD diagnosis in 25-60% (Jeste et al., 2008; Granader et al., 2010; Vignoli et al., 2015), and cognitive impairment in 50-75% (Yang et al., 2017). Disrupted patterns of neuronal connectivity account for atypical neurodevelopment in TSC (Peters et al., 2012; Julich & Sahin, 2014). No studies to date have measured disrupted patterns of neural function and connectivity in infancy that precede behavioral signs of ASD in TSC. EEG studies in infants with TSC can help elucidate neural mechanisms underlying atypical development and inform the development of biomarkers of change with early intervention.
Objectives: We examined electrophysiological (EEG) metrics of alpha oscillations (6-12 Hz) in infants TSC, with focus on alpha phase coherence (APC) and peak alpha frequency (PAF) (Dickinson *et al.*, 2017).We had three specific aims: (1) Do PAC and PAF differ between infants with TSC and infants without TSC? (2) Do APC and PAF differentiate those infants with TSC who develop ASD from those that do not develop ASD? (3) Does PAF predict cognitive function at 36 months in infants with TSC?

Methods: As part of a longitudinal multi-site study of ASD prediction in TSC (PI: Nelson), spontaneous EEG data were collected at several time points across the first two years of life in infants with TSC, alongside a low risk (LR) comparison group without TSC. Infants with TSC were then subdivided into TSC/ASD or TSC/no ASD based on clinical evaluation of ASD symptoms at 36 months (Jeste et al, 2014). After extensive cleaning using independent component analysis (ICA), EEG data were transformed into current source density (CSD) estimates using a Laplacian transform. Alpha phase coherence was computed between every possible electrode pair combination. Peak alpha frequency was estimated using a robust curve-fitting procedure for three regions of interest: frontal, central and occipital.

Results: (1)At 12 months, infants with TSC (M=.24, SD=.03; N=18) showed hypoconnectivity in long range interhemispheric alpha phase coherence compared to LR controls (M=.31, SD=.09; N=20) (P<0.00013, adj P<0.04). At 24 months, PAF was lower in TSC (N=28) infants compared to LR controls (N=12) across frontal (P=.009) and central (P=.026) regions. (2) At 24 months, infants with TSC/ASD (M=0.23; N=14) showed a pattern of long range hypoconnectivity compared to TSC/no ASD (M=0.28; N=13). (3) Across all participants, PAF at 24 months was associated with verbal (P=.001) and

non-verbal cognition (P<.001) at 36 months.

Conclusions: Alterations in functional neural development can be quantified in infants with TSC, with patterns of long range hypoconnectivity and slower peak alpha frequency, most prominent in those with ASD and developmental delay. These biomarkers of atypical development in TSC can (1) help us to further stratify risk, identifying those infants requiring targeted developmental interventions from very early in life; and can (2) inform future studies examining the effect of intervention on neural function and connectivity, as these brain changes may mediate developmental gains in these infants at high risk for ASD.

11:45 **228.004** Early Disruption of Neural Circuits for Social Communication in Tuberous Sclerosis Complex (TSC)

S. K. Warfield[1], *A. Prohl*[1], *B. Scherrer*[1], *J. Peters*[2], *D. A. Krueger*[3] *and M. Sahin*[4], *(1)Computational Radiology Laboratory, Department of Radiology, Boston Children's Hospital, Boston, MA, (2)Department of Neurology, Boston Children's Hospital, Boston, MA, (3)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Tuberous Sclerosis Complex (TSC) is a genetic disorder with high prevalence of autism spectrum disorder (ASD). Prior work has identified MRI features associated with ASD in both adult and pediatric TSC patients. Multiple abnormalities exist throughout the brain and alter over time, with varying degrees of severity. Comorbidities including seizures and intellectual disability are also common in TSC and add to the severity of imaging features. There is an urgent unmet need for imaging biomarkers that can be used in the first year of life to identify and direct early intervention towards infants most likely to develop ASD.

Objectives: We sought to determine if early disruption of the microstructural integrity of the neural circuitry of brain regions for social communication is associated with later diagnosis with ASD.

Methods: This research was conducted under a prospective, ongoing, multisite TSC Autism Center for Excellence Network (TACERN) study. We analysed 125 MRI scans of 50 infants between birth and three years of age, with recruitment planned for the first year of life, and annual MRI thereafter until reaching age three. 3T MRI of the brain was acquired using conventional structural MRI and diffusion MRI with multiple non-zero b-values and b=0 images with reversed phase-encoding directions for distortion compensation. Images were aligned to 1 mm^3T1-weighted MPRAGE, followed by segmentation into 114 cortical and subcortical regions so that whole brain single-peak diffusion tensor imaging (DTI) and multi-peak diffusion compartment imaging (DCI) tractography could be performed. Neuronal circuitry measured via DTI and DCI fingerprint connectivity of the left and right fusiform gyrus to the remaining 113 compartments was determined and associated with AOSI measures of social communication assessed at 12 months.

Results: The DCI connectivity fingerprint had a direct, in-sample prediction of AOSI with a high correlation. Our quantitative analyses revealed four key findings. First, the fusiform fingerprint-estimated AOSI was significantly correlated with the actual 12-month AOSI at all time points (12mo: p<1e-06 / 24mo: p<1e-06 / 36mo: p<1e-06). The correlation was weak at 12mo (r2=0.49) but strong at 24mo (r2=0.68) and 36mo (r2=0.75). Second, the correlation monotonically increased with age (r2: 0.49 →0.68 →0.75) while the error consistently decreased with age (RMSE: 6.43 →4.71 →3.79). Third, the area under the receiver operating characteristic curve (AUC) when classifying AOSI≥10 and AOSI<10 was high and consistently increased with age (AUC: 87.8% →90.6% →94.1%).

Conclusions: The DCI fingerprint of FUSG characterized the neural circuit underlying the structure of abnormal connectivity in infants at risk of ASD. The improved specificity and sensitivity of the fixel-based DCI analysis, over DTI, was substantial. This is due to the benefit of separately characterizing fascicles and free water. In contrast, the inability of DTI to adequately represent diffusivity properties of individual fascicles lead to a poorer association. Our work demonstrates that changes in the structure of the brain in children at risk of ASD occur early in life and strongly associate with AOSI measures at 12 months.

Panel Session
Drug Discovery and Development
229 - Drug Discovery and Development in ASD
10:30 AM - 12:30 PM - Room: 517A

Panel Chairs: Joseph Buxbaum, *Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Mustafa Sahin, *Boston Children's Hospital/Harvard Medical School, Boston, MA*

This panel will begin with a summary by J.F. Hipp of the process of drug discovery and development, including the critical need for biomarkers in early stage drug development. Next, two presentations will focus on rare genetic disorders in autism. J. Serrats will show how recent genetic findings provide a platform for neurobiologically-driven drug discovery and O. Khwaja will summarize recent advances in the use of genomic medicine in these rare disorders. Finally, G.J. Pandina will discuss the critical need for robust outcome measures in ASD in order to show efficacy of interventions, as well as a study of one such measure. These four talks will provide an inclusive picture of early through late stage drug development, including biomarkers and outcomes measures, and summarize how to leverage molecular genetic discoveries in autism for the development of novel therapeutics.

10:30 **229.001** The Importance of Biomarkers for Early Drug Development

J. F. Hipp, *Neuroscience and Rare Diseases (NRD), Roche Pharma Research and Early Development, Roche Innovation Center, Basel, Switzerland*

In this presentation, I will first describe the early drug development process comprising the pre-clinical phase, phase I to establish safety, tolerability and a good understanding of pharmacokinetics, and phase II that aims at providing a proof of concept for a given indication. I will then review different types of biomarkers that are of high relevance for drug development in neuropsychiatric disorders including (1) pharmacodynamic biomarkers that allow demonstrating modulation of brain activity, (2) biomarkers that quantify specific aspects of the disease pathophysiology or symptomatology, and (3) biomarkers that could be used to identify sub-populations that respond to a specific treatment. I will illustrate the different types of biomarkers using specific examples from our work at Roche. The goal is to convey the importance, the impact, and the challenges of using biomarkers in early drug development from an industry perspective.

10:55 **229.002** Drug Discovery for Neurodevelopmental Disorders: Current Approaches for the Medicines of Tomorrow

***J. Serrats**, Takeda, San Diego, CA*

BACKGROUND. Current available therapies for neurodevelopmental disorders do not address the major clinical needs in this patient population. Many of the therapeutics being progressed through the clinical pipeline are re-purposed drugs that were developed and initially thought to address broader patient populations. We take a patient-centric approach to drug discovery and start this very challenging process by understanding patient biology, and patient symptoms, to generate precision medicines that will address clinical needs of patients with neurodevelopmental disorders.

OBJECTIVES. Our goal is to generate a discovery pipeline of pre-clinical programs that will address, once they reach clinical development, major clinical needs that are present in patients with neurodevelopmental disorders. We focus on genetic syndromes where gene mutations are known to be highly penetrant and that play a very important role in disease initiation, progression and manifestation. This focus starts with a syndrome with a known genetic lesion that can then be studied at different levels (cellular, circuitry, network and animals).

METHODS. We focus on a few genetic syndromes where the gene lesion is known. We obtain patient cells that are reprogrammed to induced pluripotent stem cells and further differentiated into cellular types of interest, like neurons and neuronal subtypes as well as glia-like cells like astrocytes. These cells are characterized throughout the different stages of development in comparison with cells that do not have the genetic mutation. Differences between both genetic backgrounds are studied to understand the differences between cells from patients with gene lesions versus cells from normally developing individuals. Furthermore, we generate 3D cellular systems where a more complex relationship among cells and glia is established. These *spheroids* can then be used to characterize connectivity differences between neurons and glia as well as electrical recordings can be obtained to start elucidating potential changes in connectivity among these more complex cellular organizations. Finally, we generate rodent models where the same mutation (or as close as possible) that is present in our patients is present in the animal model. These models are then used to characterize potential biomarkers that resemble clinical biomarkers present in our patients, which could be used to establish relationships between drug effect and biomarker changes and ideally disease effect.

RESULTS. Initial efforts in characterizing patient-derived cells are underway in our facilities, as well as generation of *spheroids* from cells derived from patients. Once phenotypes are identified and characterized, we will proceed to major screening efforts of our internal compound libraries to identify chemical leads that can modify the identified phenotypes. Additionally, alternative modalities are being studied to modify/replace gene products that may be missing or in excess in patients with neurodevelopmental disorders.

CONCLUSIONS. Recent advances in genetics and genomics are enabling the understanding of the underlying biology of patients with neurodevelopmental disorders. In addition, advancement in innovative drug discovery areas like antisense oligonucleotides, gene therapy or availability of patient-derived cells to screen small molecule libraries are opening the door to future precision medicines in neurodevelopmental disorders.

11:20 **229.003** Novel Therapeutic Modalities for Neurodevelopmental Disorders

***O. Khwaja**, Voyager Therapeutics, Inc., Cambridge, MA*

Background

The biology of neurodevelopmental disorders and ASD has benefited from the identification of genetic and molecular pathologies, particular in rare syndromic and monogenetic disorders. Drug discovery for ASD and neurodevelopmental disorders has however been constrained by limitations in the ability to adequately pharmacologically-modify genetic targets through traditional small molecule and protein engineering approaches.

Objectives

To describe novel therapeutic modalities to directly modulate RNA and DNA-based targets in neurological disorders and identify how they may be deployed in ASD and critical success factors in translating such therapies to the clinic.

Methods

We will review recent experience with gene modulation and RNA therapies with a particular focus on targeting the central nervous system, the promise and limitations of genomic medicine in ASD as well as emerging technologies that can be applied to drug discovery and development in ASD.

Results

Genomic medicine for CNS disorders are a reality and have the potential to greatly expand the drug discovery toolbox and target space in ASD. Experience with the current generation of DNA and RNA-modulating therapies also highlight areas of uncertainty and opportunity in development of next-generation technologies as well as important factors in drug candidate selection prior to entry into humans. We primarily review vector-based, oligonucleotide and small molecule approaches.

Conclusions

Advances in drug technologies are poised to have a significant impact to modulate genetically-defined targets in people with ASD. These will begin to provide answers to the salience of these targets in the neurobiology and pathophysiology of these conditions as well as a new generation of investigational therapies for ASD and associated disorders.

11:45 **229.004** Utility of Outcome Measures in ASD – Are We Measuring What We Think We Are Measuring?

***G. J. Pandina**, Janssen Research & Development, Titusville, NJ*

Background: While many different outcome measures are available to measure the core and associated symptoms of Autism Spectrum Disorder (ASD), traditionally these scales have been utilized to facilitate diagnosis, or to measure change over longer time periods. While there are both clinician (observational and interview) and caregiver/parent measures available, most frequently studies utilize parent/caregiver measures due to their extensive knowledge of the child or adult with ASD. The very nature of early clinical drug development requires that a measure that meets several criteria: 1) comprehensively measure the core symptoms of autism, and ideally some associated symptoms; 2) is responsive to change over

short time periods (ie, 3-6 months) by measuring aspects of behavior that might be expected to change with treatment; 3) is understandable from the first administration, without explanation or support from the clinician or study staff to avoid bias; 4) and avoids burnout over time by being brief and repeatable.

Objectives and Methods: This presentation will focus on the results of a recently completed caregiver cognitive debriefing study (N=50 parents/caregivers) with a validated measure of core and associated ASD symptoms, the Autism Behavior Inventory (Bangerter et al, 2017).

Results: The ABI is a part of the JAKE ® (Janssen Autism Knowledge Engine) System, a set of tools and technologies designed to optimize clinical trials for ASD. While the vast majority of comments from caregivers regarding the ABI reflected their clear comprehension of the items and concepts, small changes to item wording and examples resulted in improved acceptance and understanding and reduced scale length.

Conclusions: Examples of caregiver feedback and impact on utility of the ABI for clinical trials will be discussed.

Panel Session
Epidemiology/Population Studies
230 - Leveraging Polygenic Risk Scores to Advance Autism Epidemiology
10:30 AM - 12:30 PM - Room: 517B

Panel Chair: Diana Schendel, *Aarhus University, Aarhus, Denmark*

Discussant: Christine Ladd-Acosta, *Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

The expansion in 2018 of GWAS data on persons with autism, through the iPSYCH and Psychiatric Genetics Consortium, has finally resulted in a sufficiently powered sample size (n=46,350) to detect common variants associated with ASD. These precise SNP-based association effect estimates enable derivation of a polygenic risk score (PRS), which captures the overall burden of genetic susceptibility to ASD (ASD-PRS). Quantitative PRS measures of individual genetic liability can serve as powerful tools to address pressing questions in autism research across a wide-range of settings. This panel will showcase the use of PRS to gain insights into ASD. First, we show that the iPSYCH-PGC PRS, discovered in a predominantly European sample, also associates with ASD case status in a racially and ethnically diverse US-based epidemiology sample (Benke; SEED sample). Second, we use PRS to determine the contribution of common variants to phenotypic variation in quantitative autistic traits among a clinically ascertained familial sample (Constantino; AGRE sample). Third, we compare PRS-based measures of ASD risk to psychiatric family history-based ASD risk (Schendel; Danish iPSYCH sample). Fourth, we use PRS concepts to provide insights into ASD subphenotypes (Grove; Danish iPSYCH sample). Our discussant will summarize emerging themes and future directions in ASD-PRS research.

10:30 **230.001** Polygenic Risk for Autism Spectrum Disorder in the Study to Explore Early Development

K. S. Benke[1], *C. Ladd-Acosta*[2], *C. J. Newschaffer*[3], *M. D. Fallin*[2], *L. A. Croen*[4], *L. Schieve*[5], *J. Daniels*[6], *A. M. Reynolds*[7] *and D. Schendel*[8], *(1)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)AJ Drexel Autism Institute, Philadelphia, PA, (4)Division of Research, Kaiser Permanente, Oakland, CA, (5)Centers for Disease Control and Prevention, Atlanta, GA, (6)University of North Carolina at Chapel Hill, Chapel Hill, NC, (7)University of Colorado Denver School of Medicine, Aurora, CO, (8)Aarhus University, Aarhus, Denmark*

Background:

Autism spectrum disorder (ASD) is a polygenic disease that is moderately to highly heritable. Genome-wide association studies (GWAS) have been successful in identifying common genetic variants that predispose to complex traits.

The largest ASD GWAS meta-analysis to date includes >9 million single-nucleotide-polymorphisms (SNPs) in 18,381 ASD cases and 27,969 controls from the Psychiatric Genomic Consortium (PGC) and iPSYCH projects. These results provide, precise SNP-based association effect sizes that allow derivation of a polygenic risk score (PRS) to represent genetic susceptibility to ASD (ASD-PRS).

Objectives:

We applied GWAS effect sizes from the recent PGC/iPSYCH results to SNP data from the independent US population-based Study to Explore Early Development (SEED) to derive ASD-PRS and examine associations between ASD-PRS and ASD classification.

Methods:

SEED is a multi-site case-control study of children aged 3-5 years with ASD and a control group drawn from the general population, born between September 2003 and August 2006. Genotyping was performed on either Illumina or Affymetrix arrays and imputed using SHAPEIT and IMPUTE2. ASD- PRS was generated via pruning, thresholding and scoring in PLINK. The same process was used to derive a psychiatric cross-disorder PRS using PGC results (http://www.med.unc.edu/pgc/results-and-downloads). All ASD-PRS associations with ASD were assessed by logistic regression, accounting for sex and five principal components of genetic ancestry.

Results:

The PRS analysis included 1302 SEED children: 861 boys (467 with ASD) and 441 girls (115 with ASD). After evaluating Nagelkerke's R-squared statistic across a range of discovery p-value thresholds, we observed that pdiscovery=0.30 maximized the variance explained. All PRS associations reflect this cutoff for SNPs to be selected into the summed score. The odds ratio of ASD for a single standard deviation increase in the ASD-PRS score, adjusted for sex and genetic ancestry, was 1.42 (95%CI: 1.13, 1.78; p-value=0.0028), which explained 0.87% of the variance in ASD status. A similar finding was observed for a subset of 799 children with European ancestry (OR=1.49; 95%CI: 1.12, 2.00; p-value=0.0066), which explained 1.1% of the variance in ASD status. We also observed an association with the CrossDisorder-PRS in the full sample (OR=1.28, 95%CI: 1.09,1.49, pl=0.0021) and in children of European descent (OR=1.46, 95%CI: 1.17, 1.82, p=0.0008). In a model that includes both ASD-PRS and CrossDisorder-PRS, the odds ratio for ASD-PRS, adjusted for the CrossDisorder-PRS, was 1.43 (95%CI: 1.07, 1.92, p=0.015), and the odds ratio for CrossDisorder-PRS, adjusted for ASD-PRS, was 1.43 (95%CI: 1.14, 1.79, p=0.0017).

Conclusions:

To our knowledge, this is the first effort to leverage the PGC/iPSYCH GWAS discovery results to investigate the utility of an ASD-PRS in a population-based ASD case-control sample. We show a strong main effect indicating genetic susceptibility for ASD, in a multi-ethnic sample and stratified by European ancestry. The variance explained, though small (~1%), is similar to PGC-based PRS for other psychiatric conditions (i.e., schizophrenia). We additionally show that the ASD-PRS association persists after adjustment for a general genetic susceptibility to psychiatric disorders. Further work will compare these results to similar analyses using a non-psychiatric phenotype to confirm the specificity of this finding.

10:55 **230.002** Common Variant Burden Contributes to the Familial Aggregation of Quantitative Autistic Traits

J. N. Constantino[1], *R. E. Wagner*[2], *W. Howells*[3], *M. Panther*[1], *J. Lowe*[4] *and D. Geschwind*[5], *(1)Washington University School of Medicine, St. Louis, MO, (2)Child and Adolescent Psychiatry, Washington University School of Medicine, St. Louis, MO, (3)Psychiatry, Washington University School of Medicine, St. Louis, MO, (4)Semel Institute, University of California, Los Angeles, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA*

Background: Both rare and common genetic variation act additively to contribute to autism spectrum disorder (ASD) risk in simplex and multiplex families. Quantitative autistic traits (QAT) aggregate in families affected by multiplex ASD, but no study to date has examined the extent to which common variants contribute to ASD risk in a familial multiplex sample encompassing the entire range of QAT. Critically, large epidemiological studies have demonstrated that family members of affected individuals exhibit subclinical QAT. Further, evidence from both twin and genomic studies suggests a genetic correlation between ASD and QAT in the general population.
Objectives: The goal of this study was to employ ASD polygenic risk scores (PRS) to predict the full range of phenotypic variance comprehensively characterizing QAT and establish common variant burden in a familial sample.

Methods: In a sample of clinically-ascertained subjects (N=634) from multiplex families in the Autism Genetic Resource Exchange, including individuals with and without ASD diagnosis, we calculated the amount of variance in QAT predicted by ASD-PRS, derived from the Psychiatric Genomics Consortium (PGC) ASD Genome Wide Association Study (GWAS) (N=10,610).

Results: The ASD-PRS explained 6.8% of the phenotypic variance in our sample. Across all subjects, the estimated correlation of the ASD-PRS with QAT was r=0.24 (p=1.17e-09). In females (N=232), the correlation was r=0.31 (p<.0001); and in males (N=402), the correlation was r=0.19 (p=0.0003). Further, we found a significant interaction of sex with ASD-PRS (p<.05). In the PGC-ASD sample, genetic complex trait analysis (GCTA) revealed the SNP heritability (which by definition measures only common, additive variation) of ASD to be 17%, setting an upper limit on how much variance a PRS can explain. Thus, it is notable that these PRS results capture 40% of the possible phenotypic variance. Similar analyses using summary statistics from the recently expanded 2018 iPSYCH-PGC ASD GWAS are underway and will be presented.

Conclusions: These results demonstrate a significant contribution of common polygenic variation to the familial aggregation of QAT. PRS enrichment in families was observed in both males and females, but this polygenic burden was significantly higher in females. Since multiplex families are preferentially selected for clinically-ascertained males, de novo mutations disrupting the relationship between PRS and phenotype may be more prevalent in males in this sample. Further, PRS derived from the largest ASD-GWAS to date, the Danish iPSYCH-PGC collaboration (N=46,350), explained 2.45% of variance in ASD diagnosis in a case-control sample; an estimate which, at 6.8%, our estimate nearly triples. To further contextualize these results, two previous studies attempting to employ ASD-PRS to predict subcomponents of QATs explained only .13% and .54% of the phenotypic variance. While it is possible that due to the multiplex nature of our sample, our subjects were enriched for common variant burden, a recent study demonstrated that the degree of over-transmission of ASD-PRS did not differ between simplex subjects and PGC-ASD probands. These results speak to the critical importance of employing QAT measurement in efforts to elucidate the genetic architecture of ASD.

11:20 **230.003** Polygenic Risk Score and Psychiatric Family History in Autism Spectrum Disorder

D. Schendel[1], *T. Laursen*[1], *C. Ladd-Acosta*[2], *M. D. Fallin*[2], *B. K. Lee*[3], *K. S. Benke*[4], *J. Grove*[5], *B. Vilhjalmsson*[1], *A. Kalkbrenner*[6], *C. B. Pedersen*[1], *L. Ejlskov*[1], *P. Mortensen*[7], *A. Bøglum*[8], *O. Mors*[1], *T. Werge*[9], *M. Nordentoft*[10], *D. Hougaard*[11] *and E. Agerbo*[1], *(1)Aarhus University, Aarhus, Denmark, (2)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (4)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (5)Center for Genomics and Personalized Medicine, Department of Biomedicine - Human Genetics, Bioinformatics Research Centre, Aarhus University, Aarhus, Denmark, (6)University of Wisconsin-Milwaukee, Milwaukee, WI, (7)National Centre for Register-based Research, Aarhus University, Denmark, 8210 Aarhus V, Denmark, (8)Biomedicine, iPSYCH, Aarhus University, Aarhus, Denmark, (9)MHC-SCT. hANS CPH-UNI, Roskilde, Denmark, (10)Mental Health Center Copenhagen, Copenhagen, Denmark, (11)Statens Serum Institute, Copenhagen, Denmark*

Background: Both psychiatric family history and genetic liability are linked to autism spectrum disorder (ASD) and there is considerable familial and genetic overlap between ASD and specific psychiatric conditions.
Objectives: We performed a population-based integration of family history and genetic liability, using the ASD polygenic risk score (ASD-PRS; derived from the ASD iPSYCH-PGC GWAS), in ASD risk. We examined ASD-PRS variation associated with distinct psychiatric family histories and ASD risk from both psychiatric family history and ASD-PRS.

Methods: The iPSYCH study population comprised all Denmark-born singleton births, 1 May 1981-31 December 2005; resided in Denmark on their one-year birthday; and mother known. ASD cases comprised study persons with an ICD-10 ASD diagnosis reported through 2012 (n=16,146) to the Danish Psychiatric Central Research Registry (PCRR). iPSYCH controls comprised a random sample of 30,000 persons from the study population (2%). ASD cases and non-ASD controls in this study additionally comprised persons whose parents were born in Denmark (84% ASD cases, 84% controls) and, among these, had an ASD-PRS (91% ASD cases, 88% controls with Denmark-born parents). We defined eight non-overlapping family history categories based on PCRR diagnoses reported through 2016 in parents or full siblings: ASD; schizophrenia; developmental disorders or intellectual disability; ADHD; affective disorders; adult personality disorders; any other psychiatric diagnosis; no psychiatric diagnoses. We estimated least-squares means (LSMean) for PRS z-scores by psychiatric family history category and adjusted odds ratios (adjOR) for ASD by decile of PRS and by psychiatric family history category. All analyses were adjusted for the first 5 genetic ancestry principal components, year of birth, age at end of follow-up, sex, parental ages at birth, and having a sibling (Yes/No). ORs by PRS decile were additionally adjusted for psychiatric family history and ORs by psychiatric family history were additionally adjusted for PRS.

Results: Psychiatric family history was observed in 36% of ASD cases (n=12,346; 9% with ASD family history) versus 19% of non-ASD controls

(n=21,904; 2% with ASD family history). ASD risk increased by PRS decile (10th decile adjOR 2.21 (1.98-2.46)) and by each psychiatric family history category (highest risk, ASD family history (adjOR 6.71 (5.91-7.61); lowest risk, other psychiatric family history (adjOR 1.73 (1.58-1.90)). There was virtually no attenuation of ASD risk after adjusting PRS ORs for psychiatric family history or adjusting psychiatric family history ORs for PRS. After Bonferroni correction, among ASD cases the only significant pair-wise difference in PRS z-score LSMean by psychiatric family history was between cases with an ASD family history and no psychiatric family history. The PRS z-score LSMean of controls with an ASD family history was comparable to that of ASD cases, regardless of family history, and significantly higher than the control LSMean with no psychiatric family history.

Conclusions:

ASD polygenic burden and psychiatric family history appear to independently contribute to ASD risk, yet better understanding of factors contributing to ASD-PRS variation with psychiatric family history is warranted. Integration of individual genetic liability and psychiatric family history is critical for understanding ASD risk architecture.

11:45 **230.004** Polygenic Heterogeneity in Autism and in Related Phenotypes

J. Grove[1] *and .. The iPSYCH-Broad/MGH Autism Working Group*[2]*, (1)Center for Genomics and Personalized Medicine, Department of Biomedicine - Human Genetics, Bioinformatics Research Centre, Aarhus University, Aarhus, Denmark, (2)iPSYCH/Broad/MGH, Aarhus, Denmark*

Background: The aetiology of Autism Spectrum Disorder (ASD) is complex and largely unknown, but ASD is highly heritable with common variation estimated to explain half of the genetic risk. Shared genetics between different psychiatric disorders is well documented and genetic correlation of psychiatric disorders with phenotypes such as educational attainment and IQ has been reported. Recently, iPSYCH and Broad/MGH conducted the largest GWAS of ASD to date comprised of 13,076 cases and 22,664 controls from Denmark and subsequently meta-analyzed with 10,610 samples from the Psychiatric Genomics Consortium (PGC). As part of these analyses, we introduced a novel polygenic risk score (PRS) analysis utilizing the genetic overlap with related phenotypes to show for the first time genetic differences between the ICD10 ASD diagnostic subgroups (childhood autism, atypical autism, Asperger's syndrome, other pervasive developmental disorder, pervasive developmental disorder, unspecified).

Objectives: We expand these novel PRS analyses to ASD and attention deficit hyperactivity disorder (ADHD) comorbid subgroups (ASD/noADHD, ASD+ADHD, ADHD/noASD) and new and more powerful PRS.

Methods: iPSYCH is a population sample comprised of cases with one or more psychiatric diagnoses identified in the Danish Psychiatric Central Research Register and a 2% random sample from the corresponding birth cohort as controls. Archived dried blood spot samples for participants were identified in the Danish Neonatal Screening Biobank. DNA was extracted, whole-genome amplified and genotyped on the PsychChip, a customized HumanCoreExome chip. QC, imputation, PCA and polygenic risk scoring were conducted using the Ricopili pipeline of PGC. For the PRS, we used summary statistics from the latest GWAS of educational attainment (EA, n~766,000), intelligence (n~270,000) and 12 neuroticism items from the UK Biobank (n~200,000). These PRS were regressed on the ASD diagnostic and ASD and ADHD comorbid subgroups in a multivariate multiple regression model adjusted for principal components and genotyping batches. This model accounts for the correlation between different PRS and makes it possible to test an array of hypotheses.

Results: With the more powerful PRS, we reproduced our previous findings that sharing of alleles between ASD and EA is concentrated in Asperger's syndrome and childhood autism, but not in the other ASD diagnostic subtypes. Moreover, the EA and intelligence PRS profiles of the ASD diagnostic subgroups are now distinguishable (p=0.048). With respect to PRS for neuroticism items, we found only minor differences across ASD diagnostic subgroups but marked differences across ASD and ADHD comorbid subgroups. For example, there were significant trends for mood swing PRS ($p=1.0x10^{-88}$) and feeling fed-up PRS ($p=6.2x10^{-74}$) across the comorbid subgroups, and while ASD/noADHD and ASD+ADHD had higher PRS scores for worrying too long after embarrassment, ADHD/noASD did not ($p=8.1x10^{-14}$).

Conclusions: Although current ASD GWAS are too small to identify individual genetic loci associated with ASD subgroups, using a polygenic perspective and powerful regression method we can distinguish ASD clinical subgroups . Moreover, we can begin characterizing ASD subgroups by their PRS loading for selected behavioural phenotypes, thereby, leveraging the power of GWAS to chip away at the multidimensional biology behind ASD.

Panel Session
International and Cross-Cultural Perspectives
231 - Cultural and Structural Factors Underlying Diagnostic and Service Disparities Among Racial/Ethnic Minority Children in the U.S.
10:30 AM - 12:30 PM - Room: 524

Panel Chair: Sandra Vanegas, *School of Social Work, Texas State University, San Marcos, TX*

Discussant: Sandy Magaña, *University of Texas, Austin, Austin, TX*

For individuals with ASD, access to early identification, diagnosis, services and supports can improve children's developmental trajectories and increase opportunities for education and employment in adulthood (Kirby, Baranek, & Fox, 2016). However, numerous disparities have been identified in access to diagnosis and services for children from racial/ethnic minority backgrounds in the U.S. (Liptak et al., 2008). Children from racial/ethnic minority backgrounds are less likely to be referred for ASD diagnostic evaluations (Tek & Landa, 2012), receive ASD diagnoses later than non-minority White children (Mandell et al., 2002), and are less likely to access therapeutic services and supports (Magaña et al., 2013). Therefore, it is critical to understand the cultural and structural factors underlying these disparities to improve outcomes for racial/ethnically diverse children. In this panel, presentations will examine the cultural (e.g., language, values) and structural (e.g., therapy services, health insurance) factors that affect access to diagnosis and services among Latino, African-American, and Korean-American children/youth with ASD in the United States. This panel will characterize how families from diverse racial/ethnic cultures navigate structural systems and provide recommendations on steps to address disparities from infancy to young adulthood. This research will inform global approaches in minimizing disparities affecting individuals with ASD worldwide.

10:30 **231.001** How Do You Translate "Peek-a-Boo" When "Peek-a-Boo" Doesn't Exist? Cultural Adaptation of a Parent-Report Screening

Tool

M. DuBay[1] *and C. Rojevic*[2]*, (1)University of North Carolina, Chapel Hill, NC, (2)Occupational. Therapy, University of Southern California, Los Angeles, CA*

Background: Parent-report screening and assessment tools are frequently used to identify children showing behaviors associated with autism spectrum disorder. Most available tools were created and validated with non-minority English-speaking individuals in western countries, then translated for diverse populations. A basic forward-back methodology has traditionally been used (Brislon, 1970). However, this methodology does not sufficiently prevent translation errors and fails to account for cultural differences (Beaton et al., 2000; Gjersing et al., 2010). Without appropriate translation methods, actual rates of over- or under-identification may differ between instrument versions, possibly resulting in a poor-quality assessment tool (Soto et al., 2015). This could contribute to disparities in identification among non-English-speaking communities.
Objectives: This presentation will describe the application of a rigorous translation and cultural adaptation process for a parent-report infant screening tool, including broader implications for Latin-American Spanish-speaking populations.

Methods: Three native-Spanish translators, from a variety of linguistic and professional backgrounds, collaboratively translated the instructions, items, and answer choices of the First Years Inventory (Baranek, et al., 2013). The quality of this forward translation was checked through preliminary pretesting and back translation. All translators, original instrument creators, and research team members developed a pre-final translated version by reviewing data collected during each of these phases. The pre-final version was tested with twenty target population members using cognitive interview strategies. Identified discrepancies in semantic, idiomatic, experiential, or conceptual equivalence between each item's original intent and its meaning as understood by participants revealed areas in need of additional cultural adaptation. A final revision was developed based on qualitative and quantitative data from throughout the process.

Results: Pre-testing results indicate that Spanish-speaking parents had difficulty choosing from frequency-based answer choices. When narrating their decision-making process for selecting answer choices, parents largely considered which answer would describe typical development. This was evident in two patterns: First, parents assumed all items described typical behaviors and tended to respond positively, even to items describing atypical behaviors (i.e. reverse-scored items). Second, parents tended to adjust their answers based on their child's age. If parents felt that an item described a behavior or skill that was developmentally advanced for their child, they adjusted the meaning of the item to describe a similar but more age appropriate behavior, and answered the item according to their modification. Parents also had difficulty understanding items with descriptions of actions (e.g. gestures, pretend play, motor milestones, motor-based RRBIs), some adjectives, and complex grammatical structures. Back-translation methods yielded some false impressions of the translation.

Conclusions: When translating a tool for use with a new population, significant revisions to instructions, answer choices, and item wording may be necessary to maintain conceptual equivalence across cultures. Results illustrate the importance of pre-testing as a quality checking procedure. Without data from pre-testing, significant issues identified would likely have influenced the way Spanish-speaking parents responded to items, in turn inflating or minimizing risk-scores inappropriately. Similar patterns may be relevant for other parent-report tools and other cultural groups. Additionally, some difficulties experienced by pre-testing participants may be relevant cross-culturally.

10:55 **231.002** Identifying Predictors of Age of Diagnosis for Latino Children with ASD in a U.S. Sample

S. Vanegas[1] *and S. Magaña*[2]*, (1)School of Social Work, Texas State University, San Marcos, TX, (2)University of Texas, Austin, Austin, TX*

Background: Data from research, administrative, and public health surveillance efforts finds significant disparities in Autism Spectrum Disorder (ASD) screening and diagnosis of Latino children. Barriers that have been reported by parents often include family-level (e.g., low-income/low-resources; Liptak et al., 2008), provider-level (e.g., Spanish-speaking providers, differential treatment by providers; Zuckerman et al., 2014, 2017), and systemic-level (e.g., complexity of diagnostic system, Magaña et al., 2013) factors that present as significant obstacles. However, little is known about specific demographic or service level factors that promote earlier diagnosis among Latino children.
Objectives: The objective of this study was to identify demographic and service-level factors associated with the age of diagnosis for Latino children with ASD in a U.S. sample.

Methods: Latino families of children with ASD or Developmental Disabilities (DD) were recruited as part of a study examining the validity of Spanish-language diagnostic assessment tools. Families were recruited through parent support groups and clinics in the Midwest region of the United States. All families completed demographic questionnaires, the Autism Diagnostic Interview-Revised, and provided access to medical records to confirm their child's diagnosis and age of first diagnosis for their respective disorders. The final sample included 46 children (ASD n = 28; DD n = 18).

Results: Variables examined as possible predictors included child sex, maternal employment, maternal marital status, maternal education, household income, Spanish as home language, age of first concern, receipt of early intervention, and receipt of early childhood special education services. No group differences were found across all variables of interest. Linear regression analyses were then run separately for the ASD and for the DD groups to identify the demographic and service-level that accounted for variances in age of diagnosis. Results from a stepwise linear regression analysis found that receipt of early intervention (β = -.44) and age of first concern (β = 0.41) were significant predictors of the age of diagnosis for children with ASD, accounting for 52.7% of the variance in age of diagnosis, R^2 = .53, $F(2, 25)$ = 13.95, p < .001. Receiving early intervention was associated with a lower age of diagnosis, whereas the age of diagnosis increased when age of first concern increased. No significant factors emerged as predictive of age of diagnosis for children with DD.

Conclusions: In this study we examined demographic and service-level factors that could affect the age of diagnosis among Latino children with ASD. Overall, receiving early intervention and the child's age when parents were first concerned were significantly associated with the age of diagnosis. These findings suggest that early diagnosis of Latino children with ASD can be facilitated through early entry into the early intervention system. This can be due to early access to professionals who are knowledgeable about ASD and can therefore assist families with referrals for diagnostic evaluations and can assist families in navigating the complex educational and health care systems. This research has significant implications for improving the early identification of Latino children with ASD.

11:20 **231.003** Structural Inequities and Autism Disparities

J. S. Singh*, Georgia Institute of Technology, Atlanta, GA*

Background: Disparities in various domains of autism services including age at diagnosis, access to therapeutic interventions, and representation in special educational services exist in the U.S. Although these disparities are evident based on social factors such as race, ethnicity, and social class, there is limited qualitative research that investigates the interrelated social and structural inequities that place children and their families at risk of delayed assessment, diagnosis, and/or services.

Objectives: The objective of this research is to identify structural inequities contributing to autism services from the perspective of underserved people and their families who experience autism service disparities. Specifically, this research aims to better understand the experiences of navigating autism services among single Black women with limited resources and who rely on Medicaid, the U.S. public health insurance program for people with low income.

Methods: This research is based on in-depth interviews (*n* = 20) with single Black women who rely on Medicaid public health insurance in the U.S. All participants were recruited at a community-based autism clinic in Atlanta, Georgia. Participants were asked to describe their experiences before, during, and after receiving a diagnosis of autism for their child. All interviews were audio recorded, transcribed, and coded using grounded theory methods.

Results: Structural inequalities evident in the data circulate around issues of government systems of care - such as the limits of Medicaid services or bureaucratic mechanisms within state-operated family and child services; quality of education – including under-resourced inner-city and racially divided schools; lack of flexibility in work policies, especially for women; and the boundaries created through public transportation. These structural inequities are also embedded in historical housing and transportation policies in Atlanta, Georgia, which have shaped limitations in public transportation and racial segregation. Based on the experiences of single Black women who are raising a child with autism, these structural inequities do not operate in isolation but work together and are mediated by race, gender, and social class. These intersecting forms of structural inequities contribute to the disparities evident in autism services and disproportionately shape the challenging and frustrating experiences of navigating autism services among single Black caregivers.

Conclusions: The perspectives of navigating autism services for single Black women with limited resources begin to make visible the complexity and embodied experience of raising a child with autism in a structurally unequal society. These alternative experiences have been excluded in the representations of autism disparities thus far and offer important insight to the inextricable link between autism disparities and the structural, historical, and situational contexts of Black women's lives as shaped by race, social class, and gender. Although this research focused on single Black women, this knowledge can certainly help us imagine experiences of other marginalized groups who confront differential access to autism services. Further, the insight from these women offers important ways forward to address autism disparities, including the development of mobile therapy units or community resource supports for under resourced neighborhoods.

11:45 **231.004** Future Service Planning for Korean-American Parents Raising Children with Autism Spectrum Disorder (ASD)

I. Kim[1]*, S. Dababnah*[2] *and Y. Wang*[3]*, (1)School of Social Work, University of Maryland, Baltimore, Baltimore, MD, (2)University of Maryland, Baltimore, Baltimore, MD, (3)Social of Social Work, University of Maryland, Baltimore, Baltimore, MD*

Background: The transition to adulthood is an ongoing process that starts in early childhood and continues through adolescence. Individuals with autism spectrum disorder (ASD) and their families can experience unique challenges during transition periods. Parents' future service plans for their children vary by culture. In the U.S., independence and autonomy are dominant values in adulthood, which shape expectations for social services for adults with ASD. However, parents from minority ethnic groups in the U.S. often hold different values and views of services designed to support these transitions.

Objectives: This study examines future service planning among Korean-American (KA) parents raising children with ASD in the U.S.

Methods: We utilized a qualitative, in-depth interview method. Fourteen first-generation KA parents (10 mothers; 4 fathers) participated in the study. The average age of the children was 16.1 years (SD=7.2). All children resided in parents' homes in the southeast U.S. None of the adults with ASD (*n*=4) were employed. The semi-structured interviews ranged from 60-90 minutes. We conducted a thematic analysis of the interview transcripts concurrent with data collection to develop primary themes.

Results: We identified three themes. First, all of the mothers placed a low value on their child's future independence. They preferred their children live at home as long as possible. However, this was a point of conflict with fathers in the study, who primarily hoped to develop plans for their child's independence. Nonetheless, both fathers and mothers indicated a desire to employ their children in their own businesses in the future, rather than in outside employment.

Secondly, few parents utilized mainstream services for their children with ASD. KA parents who resided in America for more than 20 years reported that they used mainstream services when their child was young, but encountered challenges, such as food aversions or high costs, in adult day programs or group homes. Some parents indicated a preference for Korean service providers. However, several participants reported that their state family support funds could not be used for a day program administered by their Korean churches.

Lastly, some participants, particularly recent immigrants or those who lived in areas without a large Korean community, lacked information and support regarding service planning. All parents of older adolescents or adults indicated that their final IEP meeting did not provide their child with an adequate transition plan. Some parents considered returning to Korea, where they perceived vocational training was more comprehensive.

Conclusions: Parents need support to navigate an increasingly complex service system as their children transition to adulthood. Participants, especially mothers, expressed a cultural mismatch with the individually focused U.S. service system. More funding for parents caring for their children at home, or with the support of community-based providers, is necessary. Furthermore, training ASD service providers to be culturally responsive to the needs of ethnic minority individuals with ASD and their families is critically important. KA parents who recently immigrated or who do not live in a large KA community might need more assistance to care for their children throughout their lifespan.

Panel Session
Service Delivery/Systems of Care
232 - Examining Experiences of Individuals in Communities from Diagnosis to Adulthood: Results from a Large State Needs Assessment Survey
10:30 AM - 12:30 PM - Room: 516ABC

Panel Chair: Lindsay Shea, *A.J. Drexel Autism Institute, Philadelphia, PA*

Discussant: Paul Turcotte, *Drexel University, Philadelphia, PA*

More than 8,000 adults with autism and caregivers of individuals with autism of all ages responded to the Pennsylvania Autism Needs Assessment, which covered a wide range of topics from individual demographic and clinical characteristics to service experiences. Most respondents consented to link their survey to secondary claims data, allowing for a robust data source capturing both individual opinions and preferences and observed service usage. The purpose of this panel is to present a series of focused analyses reaching from early diagnosis experience through adulthood community participation and living arrangement status and satisfaction. At the conclusion of this panel, attendees will have learned from a large dataset new information about autism diagnosis, self-reported health status, community participation, and living arrangement data. Attendees will also learn about opportunities to link individual survey data to secondary data sources to amplify the utility of results and more thoroughly observe individuals' and family experiences.

10:30 **232.001** Self-Reported Health Status Among Individuals with Autism

P. F. Turcotte[1], *K. Verstreate*[2], *K. Croce*[2], *S. Nonnemacher*[3] *and L. Shea*[4], *(1)Drexel University, Philadelphia, PA, (2)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (3)Pennsylvania Bureau of Autism Services, Harrisburg, PA, (4)A.J. Drexel Autism Institute, Philadelphia, PA*

Background:

As service systems evolve for individuals with autism, self-reported health status is an integral method to understand how individuals with autism and their families perceive their healthcare and service needs.[1] Self-rated health is used in the other disabilities and diseases, as well as in limited previous autism-specific research to detect and track changes in health status across medical and physical domains.[2,3] Previous research has demonstrated that needs of individuals with autism change as they age.[4]

Objectives:

- Identify demographic characteristics and other predictors of self-reported health status changes over the previous year.
- Leverage free text responses to categorize and qualify changes in self-reported health status

Methods:

The Pennsylvania Autism Needs Assessment , conducted in 2017, included a survey of individuals with autism over 18 years of age responding for themselves, and a survey of caregivers of individuals with autism of all ages. Information on demographic characteristics, service needs, and self-reported health, as well as a range of other topics was collected. Self-reported health status change over the previous year was reported as better, worse, or the same. Free text responses were available to explain reasons for the change in status.

Results:

Individual with autism over the age of 18 (n=1,250) were an average age of 28 and were predominately Caucasian (81.4%). Most individuals' health remained the same (67.2%), followed by 19.9% reporting "better", and 12.9% reporting "worse." Individuals who reported "worse" health outcomes were less likely to be living with parents (58.3% vs 75.1% for "same" and 70.3% for "better" respectively) and were living independently with support or in a group home, had lower average income, lower rates of private insurance coverage, and a higher level of comorbid mental health diagnoses.

The average age of an individuals with autism for whom a caregiver responded (n=5,382) was 15, and this group was also predominately Caucasian (81.4%). Most caregivers reported their child's health remained the "same" (64.6%), followed by 24.7% reporting "better", and 10.7% reporting "worse." Caregivers who were responding for children of younger ages were more likely to have selected "better", especially in the 0-5 age range (15.5% better, 6.0% the same, and 6.6% worse). This relationship switches as the child's age increases, and caregivers of individuals with autism who were 16-20 years old age reported 16.7% better,24.3% the same, and 25.0% worse.

Conclusions:

Most adults with autism (87.1%) and caregivers responding about their child (89.3%) reported that their health remained the same or improved over the previous 12 months. There were important differences in self-reported health status over the past year, including the age of the individual with autism, as well as the living situation and income. Additional analyses will use logistic and linear regression methods to identify predictors of a "worse" self-reported health status change, including comorbid diagnoses, hospitalizations, and other socio-economic factors. Qualitative analysis of the "other" text response will determine if other reasons for self-reported health status caused changes.

10:55 **232.002** Community Participation Experiences and Preferences Among Adults with Autism

W. Schott[1], *K. Verstreate*[1], *K. Croce*[1], *P. F. Turcotte*[2], *S. Nonnemacher*[3] *and L. Shea*[4], *(1)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Pennsylvania Bureau of Autism Services, Harrisburg, PA, (4)A.J. Drexel Autism Institute, Philadelphia, PA*

Background:

As the prevalence of autism spectrum disorder (ASD) has increased, growing numbers of adolescents with ASD are aging into adulthood. Advocacy organizations and new policy directives at the federal level have called for increased attention to successful community integration of adults with ASD.[1,2] Research on neurotypical populations has suggested that active and meaningful integration in one's community is beneficial, including decreased social isolation,[3-5] increased wellbeing,[6,7] improved quality of life,[8,9] improved feelings of depression and anxiety, and improved self-rated health.[10] Limited research on community participation among individuals with ASD has primarily focused on children. Compared to their neurotypical peers, children with ASD participate at lower rates in recreation, leisure, social, and community-based activities and events.[11-13] One study of young adults found that community participation among individuals with ASD was significantly lower than that of their neurotypical peers.[14] It remains unclear whether benefits from community integration for adults with ASD would be similar, whether current participation levels align with individual preferences and community characteristics, and whether additional supports, policies, and programs are needed to facilitate community integration.

Objectives:

- Characterize levels of community participation and satisfaction with participation
- Examine differences in community participation by race, income level, urban vs. rural residence, and level of service support.

Methods:

We examine data from a statewide survey of individuals with ASD in Pennsylvania (PA) conducted by the ASERT Collaborative and commissioned by the PA Bureau of Autism Services. The survey collected information on demographic characteristics, service needs, and community integration, among other topics, in 2017. Community integration was measured by the Temple University Community Participation measure (TUCP), a standardized measure examining community participation and allowing adult respondents to report on frequency of participation in a range of activities and the value they place on those activities.

Results:

The average age of adult respondents (n=1,302) was 28 (range 18-98); 29% were female, 83% were White, 21% lived in urban areas, and 72% lived with a family member. Less than half (44%) reported participation in social activities with friends, and fewer than one in three (30%) participated in groups, clubs, or organizations. About one quarter (26%) participated in volunteer work. Of these activities, the most time was spent on social activities with friends (average 5.3 hours per week).

Most respondents felt they "did not participate enough" in advocacy groups (69%), social groups (70%), civic or political activities (70%), and library activities (58%). However, participation in these activities was "important" for many: social groups were important for 43%, library activities for 38%, advocacy groups for 25%, and civic/political activities for 19%.

Conclusions:

Most adults with autism surveyed said they did not participate enough in a range of community activities. However, for a substantial portion, these activities were viewed as important. Strategies to assess and meet individual preferences for community integration, both in frequency and scope, are needed. These could include enhanced home and community-based service supports, additional service coordination, expansive dissemination of integration opportunities, and ongoing evaluation of satisfaction with current levels of community integration.

11:20 **232.003** Establishing Correlates of Successful Living Arrangements Among Adults with Autism

S. Nonnemacher[1], *K. Verstreate*[2], *P. F. Turcotte*[3], *K. Croce*[2], *W. Schott*[2] *and L. Shea*[4], *(1)Pennsylvania Bureau of Autism Services, Harrisburg, PA, (2)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (3)Drexel University, Philadelphia, PA, (4)A.J. Drexel Autism Institute, Philadelphia, PA*

Background: A common benchmark during the transition from adolescence into adulthood is to move out of a parent or family home and into independent living, with or without roommates. Previous research has found that equal proportions (42%) of adults with ASD expect to reside and not to reside with their parents as they transition into adulthood.[1] Research summarizing the variability in reported rates of independent or semi-independent living stresses the wide range of the proportion of adults with ASD living independently and that those fluctuations are highly dependent on ASD presentation (e.g., with or without ID).[2] The majority of this previous research has relied on relatively small sample sizes and generally included only adults with ASD who are described as 'high functioning.' Additional research remains needed across larger and widely varying ASD populations to establish estimates of adults with ASD across living arrangements and describe their characteristics.
Objectives: The objectives of this study are to describe rates of living arrangements across a large, statewide sample of adults with ASD, and to determine correlates of living arrangement satisfaction reported by adults with ASD.

Methods: The Pennsylvania Autism Needs Assessment, completed in 2018, is a statewide survey of adults with ASD over the age of 18 completing the survey for themselves and an accompanying survey of caregivers of individuals with ASD of any age. More than 1,100 adults with ASD completed the Pennsylvania Autism Needs Assessment and the majority of these individuals consented to have their survey responses linked to their Medicaid claims data. The type of living arrangement as well as satisfaction with the living arrangement was reported by adults with ASD. Additional analyses will merge demographic and clinical data, as well as other characteristics of adults with ASD to report on living arrangements among adults with ASD.

Results: Most (72.0%) adults with ASD who completed the survey for themselves reported living with their parents, relatives, or in a family home. The next most common living arrangements were living independently with support (7.0%), living independently without support (5.7%), and living with a roommate or spouse (5.5%). The majority (82.3%) of adults with ASD reported they were happy or very happy with their current living arrangement, but almost one in five (17.7%) adults with ASD reported they were unhappy or very unhappy with their living arrangement. Additional results focused on differences in living arrangement and satisfaction by living arrangement will be stratified by age, symptom presentation, geographic location, and other factors will be produced using logistic regression.

Conclusions: Most adults with ASD who responded to the PA Autism Needs Assessment were living at home, as has been reported in previous research. Most adults with ASD were also satisfied with their living arrangement, although this dimension of independent living has been relatively unexplored in precious research. Additional analyses to describe and understand living arrangement preferences, successes, and challenges among adults with ASD will be conducted and produced.

11:45 **232.004** Comparing Parent-Reported Autism Diagnoses to Administrative Claims

L. Shea[1], *P. F. Turcotte*[2], *W. Schott*[3], *K. Croce*[3], *K. Verstreate*[3] *and S. Nonnemacher*[4], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Drexel University, Policy and Analytic Center, A.J. Drexel Autism Institute, Philadelphia, PA, (4)Pennsylvania Bureau of Autism Services, Harrisburg, PA*

Background:
Surveys of parents and caregivers for individuals with autism present a unique opportunity to gain valuable information about the diagnosis experience. Previous research has found that the diagnostic process for children with autism is often confusing for parents, that diagnostic terminology is difficult to understand, and that the length of time the diagnostic process takes to complete is stressful and disorienting.[1]

Comparing parent-reported experiences of the diagnosis process to administrative data allows for the detection and prioritization of opportunities to provide needed information to parents and caregivers navigating the diagnostic process. [2,3]

Objectives:

- Determine overlap of parent-reported diagnoses for their children and administrative records, before and after an autism diagnosis.
- Identify child- and parent-level characteristics that predict alignment in parent-reported diagnoses and diagnoses captured in administrative data.

Methods:

The Pennsylvania Autism Needs Assessment, conducted in 2017, included a survey of parents/caregivers of all ages. Information on demographic characteristics, service needs, and self-reported health, as well as a range of other topics was collected. Parents answered multiple questions about the diagnostic process, including diagnoses received before an autism diagnosis for their child, as well as diagnoses that are currently present. In addition, parents could consent to link their survey responses to administrative claims data for their child. This sample includes 530 children under age 11 whose parents consented linking to their administrative records.

Results: The average age of the children for whom a caregiver responded was 7.1 years old. Most children were male (79.9%) and were predominately Caucasian (82.9%). About half (49.4%) of the caregivers indicated that getting a diagnostic evaluation for their child was somewhat or very difficult. About two thirds (68.2%) indicated receiving at least one prior diagnosis to their autism diagnosis. The most common diagnoses reported before receiving an autism diagnosis were Developmental Delays (43.4%), ADHD (21.5%), and Learning Disability (12.8%). The most common current diagnoses were ADHD (39.1%), Developmental Delays (33.7%) and Anxiety Disorder (21.3%). These diagnoses will be linked to administrative records to determine if the diagnoses were present prior to the autism diagnosis, and if the child had services billed for the diagnoses. Socio-economic factors, child age, and overall experience of obtaining an autism diagnosis ("easy" vs "difficult") will be examined to determine predictors of alignment in parent-reported diagnoses.

Conclusions:

Previous research has examined validity of parent-reported diagnoses in autism populations with the goal of understanding and supporting the diagnostic process.[4] Determining differences in how families understand the diagnoses a child may have is important for treatment planning. Recent research on the parent-reported prevalence of autism underscore the importance of examining the feasibility of using administrative claims to validate parent-reported.[5] This research also has important implications regarding resource development and policy planning to better support families in the diagnostic process, and to quantify the role of socio-demographic factors and other characteristics in facilitating an accurate and timely autism diagnosis.

Poster Session
233 - Adult Outcome: Medical, Cognitive, Behavioral, Social, Adaptive, Vocational
11:30 AM - 1:30 PM - Room: 710

1 **233.001** Self-Harm and Premature Death in Young Individuals with Autism – Preliminary Results from a Total Population Study in Sweden

I. Stark[1], *D. Rai*[2], *N. Döring*[3], *S. Idring Nordström*[4], *M. Lundberg*[4] *and C. Magnusson*[5], *(1)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (2)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (3)Public Health Department, Karolinska Institutet, Stockholm, Sweden, (4)Department of Public Health, Karolinska Institutet, Stockholm, Sweden, (5)Karolinska Institutet, Stockholm, Sweden*

Background:

There is increasing concern that people with autism are more likely to die prematurely, particularly by suicide. However, there are little data on the extent of increased mortality and on risk and protective factors. While self-harm behavior in typically developed individuals is a strong predictor of later suicide and death by any cause, its characteristics and impact on mortality in autism is unknown. A detailed understanding of these matters are crucial for prevention of premature mortality in autism.

Objectives:

To examine the association between self- harm and mortality (all cause and by suicide) across the whole spectrum of ASD in a nation-wide contemporary cohort of adolescents and young adults in Sweden. To investigate risk and protective factors in this association, with emphasis on sex, co-morbid conditions, familial and social characteristics.

Methods:

We conducted a total population study using data from Psychiatry Sweden, a comprehensive record-linkage study. Data on probands, followed-up from 10 to maximum 32 years of age by 2016, their first and second degree relatives, was collected prospectively by record linkage. A total 2 372 500 individuals (51.4 % male), of whom 49 633 were diagnosed with autism (66.3% male) were included in the analyses. The total number of deaths was 8 417.

Exposure was cross-classified as a diagnosis of autism and at least one episode hospital admission for self-harm (ICD-10 codes X60-84 and Y10-34). The outcome was subsequent death, by any cause and by suicide, determined from national Cause of Death Register. Cox hazard proportional regression models were used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) of death by any cause and by suicide in four groups; neither autism nor self-harm, autism without self-harm, self-harm without autism, and autism with self-harm.

Results:

Among individuals diagnosed with autism, 0.2% with no history of self-harm and 3.4% of those with a history of self-harm had died by suicide. The adjusted HRs of suicide in autism without self-harm and in self-harm without autism were 2.4 (95% CI 1.8-3.2) and 20.7 (18.1-23.7), respectively. Among those with both autism and self-harm, the adjusted HR was 42.7 (33.3-58.8). Further results on risk and protective factors in the association

between self-harm (including characteristics of the self-harming behavior) and suicide (as well as all-cause mortality) will be presented.

Conclusions:

Our findings indicate that individuals with autism who engage in self-harm have a particularly elevated risk of premature death and suicide. This suggests that identification and treatment of this subgroup is important, and that clinical guidelines for suicide risk assessment may have to be revised to recognize this new knowledge.

2 **233.002** Service Use in Adolescents and Adults in Latin America. Results from a Multisite Study

C. Montiel-Nava[1], *G. Garrido*[2], *R. A. Garcia*[3], *D. Valdez*[4], *S. H. Cukier*[5], *C. S. de Paula*[6], *A. Rosoli*[7], *A. Shih*[8] *and A. Rattazzi*[5], *(1)Psychological Sciences, University of Texas Rio Grande Valley, Edinburg, TX, (2)Universidad de la República, Montevideo, Uruguay, (3)Universidad de Chile, Santiago, CHILE, (4)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (5)PANAACEA, Buenos Aires, Argentina, (6)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (7)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (8)Autism Speaks, New York, NY*

Background: Individuals with ASD are users of different type of educational and medical services. There is increasing evidence that recognizes ASD as a lifelong disorder; however, studies about type and frequency of services used by adolescents and adults within the spectrum is scarce. Objectives: This study aimed to explore perceptions about the use of services of caregivers of adolescents and adults with Autism Spectrum Disorders in Latin America.

Methods: This study was carried in 6 different countries in South America: Argentina, Brazil, Chile, Dominican Republic, Uruguay, and Venezuela. A sample of convenience was drawn from each country. The total sample was made up by 592 caregivers from Argentina, Brazil, Chile, Dominican Republic, Uruguay, and Venezuela. 49.83% (n=295) were adolescents (13-18 years-old), and 50.17% (n=297) were adults (>18 years-old). Caregivers completed a survey either by an interview, by phone, or online, either assisted by a clinician or not. The survey contains four sections: family demographics, affected individual characteristics, service encounters and parent/caregiver perceptions.

Results:

The most prevalent diagnosis among adolescent's sample was Asperger Syndrome (33.22%) followed by ASD (26.10%). For the adults, Asperger was the most common diagnosis as well (35.69%), followed by Autism (28.62%). 11.85% of the adolescents and 21.54% of the adults had at least one medical comorbidity. For both age groups, Epilepsy was the most frequent comorbidity. The most common type of service used was medication (41.02% in adolescents, and 48.48% in adults); followed by physical therapy (26.77% in adolescents, 24.93% in adults), and Behavior Therapy/Behavior Modification (24.41% in adolescents, 24.93 in adults). The least commonly reported services were psychodynamic therapy (16.94% in adolescents, 15.15% in adults), biomedical treatments (0.68 in adolescents and 8.08% in adults), and relational therapy (floor time and sonrise) (0.34% in adolescents, 2.02% in adults). There was statistical significance between the two age groups for the frequency of use of medication (x^2=139.954, α=0.001) biomedical treatments (x^2=25.313,α=0.001), and relational services (x^2=15.868,α =0.14).

Conclusions: Although exploratory data from caregivers in Latin America results from our sample suggest a decrease in the use of services from adolescence to adulthood. Only medication, psychodynamic therapy, and biomedical treatment were more frequent in adults than adolescents. It could be a function of the scarce availability of services for this population in Latin American countries. It could also describe a more medical oriented approach or conceptualization of ASD in this culture. With a representation of 6 countries, results have clear implications for public health and educational policies and practices

3 **233.003** The Influence of Autistic Traits and Trait Anxiety on Attentional Bias to Emotional Faces: An Eye-Tracking Study in Healthy Young Adults

W. Wu[1], *B. Wan*[1] *and J. Jing*[2], *(1)Sun Yat-sen University, Guangzhou, China, (2)Maternal and Child Health, Sun Yat-sen University, Guangzhou, China*

Background: Healthy individuals, as well as adults with autism, usually demonstrate the anger superiority effect (ASE), i.e., reaction time (RT) to angry faces faster than positive faces, which is not associated with anxiety. While, in addition to the ASE, the time duration of negative relative to positive faces can reflect the emotional processing in the field of attentional bias. Yet, it is unknown whether autistic and anxiety level affect the emotional processing or not.

Objectives: The present study aimed to clarify the association between autistic traits/trait anxiety in healthy young adults and the time duration of negative relative to positive faces with a free-view paradigm.

Methods: We recruited fifty-two healthy adults (age: Mean=20.8, range 18~25 years, sixteen males), and their autistic traits and trait anxiety were self-reported using Autism Spectrum Quotient (AQ, including five subscales of autistic behavior: social skills, attention switching, attention to detail, communication, and imagination) and State-Trait Anxiety Inventory (STAI) respectively. Total fixation duration (TFD) and first fixation duration (FFD) indices of attention bias to emotional information [negative (angry and sad) and positive (happy), compared with neutral faces] were calculated in Tobii Spectrum Pro software.

Results: The individuals' trait anxiety level was positively correlated with AQ total, social skills, attention switching, and communication scores (r=0.504, 0.421, 0.419, 0.456, respectively; df=50; all p<0.005). There was no significant correlation between autistic traits/trait anxiety and TFD/FFD of negative relative to positive faces. Nevertheless, the trait anxiety was significantly correlated with FFD of angry relative to happy faces (r=-0.298, df=50, p=0.032); and AQ social skill was significantly correlated with FFD of sad relative to happy faces (r=0.304, df=50; p=0.028). The associations were robust with adjustment for age, sex and state anxiety during the eye-tracking experiment.

Conclusions: Our findings suggest that adults with deficit of social skills show long-term attention of sad relative to happy faces and adults with higher trait anxiety show short-term attention of angry relative to happy faces in emotional processing. The present study provides preliminary results for emotional processing in clinical autism spectrum disorder and clinical anxiety disorder.

4 **233.004** Sex Differences in Cognitive and Symptom Profiles of Older Adults with Autism Spectrum Disorder

M. Walsh[1], *L. C. Baxter*[2], *C. J. Smith*[3], *E. Foldes*[4], *C. Webb*[4], *A. Gonzales*[5] *and B. B. Braden*[4], *(1)Arizona State University, Tempe, AZ, (2)Radiology, Barrow Neurological Institute, Phoenix, AZ, (3)Southwest Autism Research & Resource Center, Phoenix, AZ, (4)College of Health Solutions, Arizona State*

University, Tempe, AZ, (5)Arizona State University, Phoenix, AZ

Background: Theories have suggested that females with autism spectrum disorder (ASD) demonstrate higher levels of symptom masking relative to males, and a proposed masking mechanism is executive functioning. Declines in executive functioning are a hallmark of normal aging and are also observed in aging adults with ASD, suggesting that aging may reduce masking abilities. Furthermore, if females with ASD are preferentially engaging executive function strategies for symptom masking, aging may have a greater effect on age-related symptom exacerbation for females than males. However, no studies have characterized executive function sex differences in an older adult sample and its relationship with ASD symptoms.

Objectives: We aimed to provide a preliminary characterization of sex differences on two measures of executive functioning in mid-to-older adult men and women with ASD and its association with ASD traits.

Methods: Participants were mid-to-older (40-70 years) adult men or women of average intellectual functioning with ASD or NT development (female ASD: *n*=11; female NT: *n*=12; male ASD: *n*=29; male NT: *n*=23). Sex, diagnosis, and sex by diagnosis interactions were examined using Analysis of Variance for a behavioral regulation (Wisconsin Card Sorting Task; WCST) and a metacognitive (Tower of London; ToL) measure of executive functioning. Relationships between executive functioning and ASD traits were examined using the Social Responsiveness Scale – 2nd Edition (SRS-2) Social Cognition Subscale and the Adult Repetitive Behaviors Scale (RBQ-2A). IQ was included as a covariate in all analyses.

Results: For WCST, there was a significant main effect of diagnosis ($F_{1,71}$=12.878, p=0.001) and a significant diagnosis by sex interaction ($F_{1,71}$=4.030, p=0.049). Both women and men with ASD made more errors than their NT counterpart (women: p=0.004, novel finding; men: p=0.044, one-tailed replication); but, the magnitude of difference was greater for women with ASD (women: d=0.97; men: d=0.48; Fig. 1a). No significant main effects or interaction were observed for the ToL. However, exploratory post hoc analysis showed that females with ASD demonstrated more planning errors than males with a moderate effect size (d=0.46) that approached significance (p=0.107; Fig. 1b). In male and female ASD groups, correlations were observed between the SRS-2 Social Cognition Subscale and ToL performance, such that worse ToL performance was associated with increased ASD-related social behavior (female ASD: r_7=0.70, p=0.036; male ASD: r_{27}=0.39, p=0.045; Fig. 2a). Alternatively, the RBQ-2A showed a correlation with WCST performance in females with ASD but not males (female ASD: r_8=0.70, p=0.026; male ASD: r_{21}=-0.09, p=0.69), such that more errors were associated with increased repetitive behaviors (Fig. 2b).

Conclusions: In one of the first investigations of sex differences in mid-to-older adults with ASD, this study shows a tendency toward greater executive function difficulties in women with ASD, compared to men with ASD. Furthermore, women with ASD showed stronger associations between ASD traits and executive functioning than men. This suggests that older adult women with ASD may capitalize even further on executive functioning for symptom masking relative to men with ASD. Longitudinal research on sex differences in age-related cognitive and symptom changes are warranted.

5 **233.005** Sleep Determines Quality of Life in Autistic Adults: A Longitudinal Study

M. K. Deserno[1]*, D. Borsboom*[1]*, S. Begeer*[2]*, J. Agelink van Rentergem*[3]*, K. Mataw*[4] *and H. M. Geurts*[5]*, (1)Department of Psychology, University of Amsterdam, Amsterdam, Netherlands, (2)VU University Amsterdam, Amsterdam, Netherlands, (3)Psychology, University of Amsterdam, Amsterdam, Netherlands, (4)Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (5)University of Amsterdam, Amsterdam, Netherlands*

Background: Many individuals with autism report generally low Quality of Life (QoL). Identifying predictors for pathways underlying this outcome is an urgent priority.

Objectives: We aim to examine multivariate patterns that predict later subjective and objective QoL in autistic individuals.

Methods: Autistic characteristics, comorbid complaints, aspects of daily functioning and demographics were assessed online in a two-year longitudinal study with 598 autistic adults.

Regression trees were fitted to baseline data to identify factors that could predict QoL at follow-up.

Results: We found that sleep problems are an important predictor of later subjective QoL, while the subjective experience of a person's societal contribution is important when it comes to predicting the level of daily activities.

Conclusions:

Sleep problems are the most important predictor of QoL in autistic adults and may offer an important treatment target for improving QoL. Our results additionally suggest that social satisfaction can buffer this association.

6 **233.006** Social Conversational Improvements Associated with the Social Tools and Rules for Transitions (START for Young Adults with ASD) Program

S. J. Cohen*, J. A. Ko, E. McGarry, A. R. Miller and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Young adults with autism spectrum disorder (ASD) often struggle with social communication and relationship formation (APA, 2013; Howlin, Moss, Savage, & Rutter, 2013). These challenges are significantly associated with poorer outcomes related to academic and vocational success, mental health, and quality of life (Zager & Alpern, 2010; Eaves & Ho, 2008). Unfortunately, support resources for adults with ASD are often limited, as is research on effective interventions to support adults with ASD in their social development. Targeted group socialization interventions may be a promising model for addressing social motivation, insight, and skill deficits for this growing population (Vernon, Miller, Ko, & Wu, 2016; Laugeson, Gantman, Kapp, Orenski, & Ellingsen, 2015). Within these intervention models, socially valid measurement of social skill performance is crucial, as program participation must yield observable social conversational improvements within everyday interactions to be clinically meaningful. Coding of live peer conversations may be a promising strategy for obtaining objective measurement of social gains (e.g. Vernon et al., 2016; Mitchell, Regehr, Reaume, & Feldman, 2010).

Objectives: The present study aims to determine whether participation in the START group leads to observable improvements in the use of key social communication skills during conversations with unfamiliar peers.

Methods: The Social Tools and Rules for Transitions (START) program is a 20-week peer-mediated socialization group intervention that combines experiential learning and instructional lessons, in addition to weekly social outings in the community that serve as "field work" settings to practice the targeted social strategies. A randomized clinical trial was used to assess the efficacy of this intervention with 28 adults with ASD, aged

18-25. Participants were randomly assigned to an immediate treatment or waitlist control group. At pre- and post-intervention, all participants completed two video-recorded 5-minute "get to know you" conversation probes with unfamiliar, untrained young adult peers who were unaware of study hypotheses and the diagnostic status of the participants. Videos were coded for both verbal (social inquiries made, conversational turn taking) and nonverbal social communication strategies (eye contact, directed facial expressions). 25% of all videos were coded by a second naïve rater to assess inter-rater reliability. Repeated measures ANOVAs were to determine whether the treatment group shows significant improvements over time, compared with the control group.

Results: Preliminary coded conversational data from a subset of the total trial cohort is indicative of significant increases in verbal and nonverbal social communication behaviors unique to the START participant group. Video coding and data analysis of the entire trial cohort will be completed by March 2019.

Conclusions: Preliminary data is indicative of live social conversational improvements in participants of the START program for young adults. Such data is indicative of an objective and observable enhancement of social functioning that can be applied to future peer interaction and relationship formation.

7 **233.007** Supporting Employers in Hiring Young Adults on the Autism Spectrum: Lessons Learned from a Corporate Internship Program

C. J. Grantz[1], *A. Gulsrud*[2], *E. A. Laugeson*[3] *and J. McCracken*[4], *(1)Psychiatry, UCLA Semel Institute CAN Clinic, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA, (4)UCLA Semel Institute, Los Angeles, CA*

Background: Young adults with ASD have poor postsecondary employment outcomes, with high rates of unemployment or underemployment. Employers are becoming aware of the skills young adults with ASD can bring to the workplace. However, lack of knowledge regarding how to best support such individuals within the workplace and concern regarding how to determine appropriate positions for such individuals are impacting employer outreach to young adults with ASD.

Objectives: The UCLA Child and Adult Neurodevelopmental (CAN) Clinic and the PEERS© Clinic are collaborating with a national company to develop employment training for college students with ASD and employer education for potential employers in the Greater Los Angeles area. The aim of the current study is to conduct qualitative interviews with employers to determine how to best support employers in hiring interns with ASD and supporting them in the workplace. Employers at the partner company who participated in a pilot internship program for young adults with ASD were invited to participate in a focus group to identify the "key ingredients" needed during the hiring and support process for individuals with ASD in the workplace.

Methods: A 1-hour focus group was led by a Licensed Psychologist with members of the company's ASD internship program, as well as members of a partner firm's pilot ASD internship. The group was audiotaped with permission from all participants, transcribed verbatim, and independently coded for major conceptual models. Exploratory, qualitative analyses was conducted using a modified grounded theory approach.

Results: Salient themes from the interview with employers included identifying appropriate expectations for interns, flexibility in management style and frequency, and flexibility in tasks assigned based upon intern strengths and weaknesses. Difficulties managing schedule, speed of completing tasks, and difficulties with flexible problem solving were reported to be significant challenges affecting intern success. Greater frequency and intensity of management, particularly when learning new tasks, was described as significantly improving intern success. The corporate culture was also described as an essential component of intern success, with both companies reporting some brief psychoeducation with employees and clients regarding interns' strengths and needs. Improved social interaction skills and confidence in managing job-related tasks were observed across the internship period. Financing for the internship program was stable, as both companies have on-going internship budgets.

Conclusions: Integrating young adults with ASD into the corporate workplace is feasible with appropriate expectations and sufficient management support. Variability in intern strengths and weaknesses impacts job content and pace; intern skills must be determined prior to the internship to ensure appropriate fit. Creating an accepting corporate culture that supports interns and their supervisors in navigating challenges is of great importance. Improvement in social functioning was reported without targeted intervention in this domain, suggesting that the workplace setting may provide in-vivo social communication training for young adults with ASD. Evaluation of employer' knowledge of, comfort with, and needs for working with individuals with ASD is needed and ongoing to support development of broader employer outreach and training.

8 **233.008** Supporting Students with Autism Spectrum Disorder in Post-Secondary Education Settings: Common Barriers and Needed Accommodations and Supports

R. T. Paskins*, Counseling and Rehabilitation, University of Wisconsin-Stout, Menomonie, WI*

Background: Although there is greater attendance in Post-Secondary Education settings, the graduation rate of students with autism is below the standard average, with some evidence of graduation rates being lower that the general population of people with disabilities. In an effort to take a step toward addressing this concern, the current study began the exploratory process of identifying whether services provided by campus disability resources centers align with the best practices that enhance the success of students with ASD.

Objectives: The purpose of this study was two-fold. The objectives were to explore: From a disability service professional perspective, what are the most common barriers that prevent students with autism spectrum disorder from completing post-secondary education? From a disability service professional perspective, what are the most beneficial supports to help students with autism spectrum disorder complete post-secondary education?

Methods: A three-round Delphi survey with expert panels consisting of disability service professionals was implemented. The study began by asking an expert panel consisting of disability service professionals to develop and agree upon a list of (a) barriers in providing academic accommodation (b) individual and systemic barriers faced by the student, and (c) supports that can help reduce these barriers.

Results: The final instrument identified 34 barriers to providing academic accommodation, 47 systemic barriers, and 37 individual barriers students with ASD experience in PSE settings. Additionally, DRC counselors identified 45 supports and services that would help address the identified barriers. Of the items identified, the expert panel was provided opportunity to compare their scores with the group mean score with the

opportunity to change their score to match the group mean. From these results the interquartile range was calculated to identify items that achieve consensus. The items which demonstrated a strong consensus (IQR < 1.5) were identified as significant.The survey items that demonstrated a median of 4.00 or above and an IQR of 1.5 or lower were considered to have high frequency and strong consensus and were therefore considered to be a high priority. Of the 163 items reviewed, 71 identified barriers met these criteria. All items identifying supports were measured by a similar level of benefit rating ranging from one to seven. The same measurement of median and IQR was applied and 35 items met the criteria and were rated as high priority.

Conclusions: The findings from this study have important implications for disability services in PSE. Notably, the identified barriers experienced, and services provided to students with ASD, may guide professional development opportunities (i.e., in-service training, workshops, etc.) for disability service professionals and other campus faculty and staff. Because of their diverse educational and professional backgrounds, disability service professionals may not be prepared to provide best practices to students with ASD. This study also could primarily impact those who face the identified barriers first hand, namely the students. If university policy makers will take into consideration the finding of this study, then a discussion of “equal opportunity,” “equal access,” and best practice can be brought to the table for further exploration.

9 **233.009** Testing Social Cognition As a Mediator between Neurocognition and Social Outcomes

***N. J. Sasson**, K. E. Morrison and A. E. Pinkham, University of Texas at Dallas, Richardson, TX*

Background: The specific contributors to poor social functioning outcomes for adults with autism are poorly understood. Neurocognitive abilities (e.g., working memory) and social cognition (e.g., social perception and appraisal) are frequently targeted in intervention studies to improve social outcomes, but to date no studies have empirically tested the contribution of these constructs to social functioning.
Objectives: We examined the relative contribution of neurocognition and social cognitive domains to predict both social skills and functioning. We also tested these constructs for mediation, hypothesizing the effect of neurocognition on outcomes is mediated through a serial pathway between social perception and social appraisal abilities.

Methods: Adults with autism (N=103; age M=24.28; 11 females) completed a battery of tasks. Social perception was measured by computing a composite score of tests measuring ability to recognize emotion in static faces (ER-40; Kohler et al., 2003; Reading the Mind in the Eyes; Baron-Cohen et al., 2001), dynamic videos (Bell Lysaker Emotion Recognition Task; Bryson et al., 1997), and point-light walkers (Emotional Biological Motion; Biological Motion; Kern et al., 2013), as well as ability to recognize faces (Benton Facial Recognition Task; Benton et al., 1968). Social appraisal was measured by computing a composite score of tasks assessing mentalizing abilities (The Awareness of Social Inference Task; MacDonald et al., 2003; Hinting Task; Corcoran et al., 1995) and the Relationships Across Domains task (Sergi et al., 2009), assessing understanding of social relationships.

Participants also completed the MATRICS Consensus Cognitive Battery (MCCB; Nuechterlein et al., 2008), measuring working memory, short term memory, and processing speed through pencil and paper tasks.

Social skill outcomes were assessed through trained coders’ average rating of six skills displayed in a three minute interaction with a researcher role-playing meeting a new neighbor (Social Skills Performance Assessment; Patterson et al., 2001). Social functioning was assessed with the UCSD Performance-based Skills Assessments (UPSA; Mausbach et al., 2007), a performance-based task measuring daily living skills.

Results: Gender, age, neurocognition, social perception, and social appraisal entered as predictors accounted for 48% of variance in social functioning scores and 30% of social skills scores. In both models, older participants and participants with stronger neurocognitive ability scored higher on social functioning and skills (ps<.001), and social appraisal ability predicted better social functioning (p=.003).

Controlling for age, we examined indirect effects and the bootstrapped confidence intervals around the estimate to test for evidence of mediation (Figure 1). The indirect serial pathway was significant in predicting social functioning (b=.08, bootstrapped lower limit=.03, bootstrapped upper limit=.15), suggesting social cognition is a mechanism through which neurocognition influences social functioning. There was no evidence for mediation in predicting social skills (b=.02, bootstrapped lower limit=-0.05, bootstrapped upper limit=.09).

Conclusions: Neurocognition is a significant predictor of social functioning and social skills for adults with autism. The mediation results show neurocognitive ability is transmitted through social perception and social appraisal ability for social functioning, suggesting interventions targeting neurocognition may benefit social cognitive skill and functioning. However, our results suggest social skill is a function of a different mechanism.

10 **233.010** Testing a Model of Sexual Minority Orientation in Individuals with and without the Broad Autism Phenotype

***L. R. Qualls**[1,2], N. Kreiser[2], J. F. Paulson[3] and K. Hartmann[2], (1)Virginia Consortium Program for Clinical Psychology, Norfolk, VA, (2)Eastern Virginia Medical School, Norfolk, VA, (3)Old Dominion University, Norfolk, VA*

Background: Individuals with the Broad Autism Phenotype (BAP) are similar to those with Autism Spectrum Disorder (ASD) in that they are more likely to endorse a sexual minority orientation than those with typical development (TD; Qualls et al., 2017). However, no empirical studies have examined factors that contribute to higher rates of sexual minority orientation in this population. A biopsychosocial model (Dillon, Worthington, & Moradi, 2011)has been tested in a pilot study with sexual minority individuals with ASD and found to have potential for explaining differences in the rate of sexual minority orientation between TD and ASD/the BAP. This model proposes that current sexual minority orientation is affected by factors related to biology, social context, culture, religion, gender norms and socialization, and systematic homonegativity.
Objectives: 1) Examine whether the biopsychosocial model described above has good fit in describing factors related to sexual minority orientation and 2) if these factors have different explanatory power for individuals with and without the BAP.

Methods: The demographics questionnaire contains questions concerning participant’s age, birth gender, gender identity, race, religion, family income, parent’s education, respondent’s education, and formal ASD diagnosis. The Broad Autism Phenotype Questionnaire (BAPQ) is used to assess for characteristics of the BAP. The Autism Spectrum Quotient-10 (AQ-10) is used to assess symptoms relating to ASD. The Klein Sexual Orientation Grid (KSOG) is used to provide an estimate of each participant’s present and ideal sexual orientation and preferences. The factors from the Worthington et al. (2002) model are measured as follows: biological, number of sexual minority family members; social contextand culture, a modified version of the Sexual Prejudice Scale (SPS); religion, Religious Orientation Questionnaire-Intrinsic (RIQ); gender norms and

socialization, the Attitudes Toward Women Scale (AWS) and the Male Role Norms Inventory-Short Form (MRNI-SF); and systematic homonegativity, Daily Heterosexist Experiences Questionnaire (DHEQ). Structural Equation Modeling (SEM) will be used to determine the relationship between the observed and latent variables and to test the fit of the proposed model in each of the groups.

Results: After one month of data collection, 43 responses that met criteria for inclusion (sexual minority, ages 18-30, complete data, no ASD diagnosis) have been collected. Collection of a further 157 responses is planned over the next four months to obtain a final N of 200 (100 individuals in each group). Preliminary data from a subgroup of 30 individuals (*M*age=22.46,19 female, 6 male, 5 transgender/genderfluid /genderqueer) revealed a positive correlation between sexual orientation and BAP traits as has been found in previous literature, $r = .38$, $p < .05$ (Qualls et al., 2017). These results should be interpreted with caution due to small sample size but are promising.

Conclusions: It is predicted that the biopsychosocial model will have adequate explanatory power for both groups. It is further predicted that while biological factors will be similar between the groups, there will be differences in psychological and social influences. Results from this study will help further define the unique characteristics of sexual minority orientation in individuals with the BAP.

11 **233.011** The Connect Project and Its Lessons for Future Multistakeholder Research on Adult Autism

C. Jose[1], *P. D. George-Zwicker*[2], *M. Robichaud*[3], *J. Gaudet*[3], *M. J. Plourde*[3], *L. Tardif*[4] *and A. Bouma*[5], *(1)CFMNB, Maritime SPOR SUPPORT Unit, Moncton, NB, Canada, (2)Autistics Aloud, Autism Nova Scotia, Bedford, NS, Canada, (3)Maritime SPOR SUPPORT Unit, Moncton, NB, Canada, (4)Government of New Brunswick, Fredericton, NB, Canada, (5)BOUMA Woodworks, Woodstock, NB, Canada*

Background: Launched in 2017 and developed under Canada's national Strategy for Patient-Oriented Research, the CONNECT project (CONtiNuity of carE and services for autistiC adulTs) was the first Autistic co-led research collaboration bringing together autistic adults, caregivers of people living with autism, researchers, service providers, and policy decision-makers from across the Maritimes Provinces.
Objectives: The goal of the project was to collect and disseminate much-needed hard data on the health, socioeconomic status and service needs of the autistic adult community living in New Brunswick, Nova Scotia and Prince Edward Island.

Methods: When nearing the closing stages of the project, the CONNECT team decided to take a step back and to reflect critically on the study's life cycle, from its genesis to the production and dissemination of its intended deliverables. Researchers were not the only ones reflecting upon their experience with this pioneering patient-engagement initiative. Patient partners also pondered the highs and lows of the CONNECT project and the lessons learned from their participation, using a feedback questionnaire to comment on such aspects as recruitment methods, group dynamics, the nature and scope of their engagement as well as the impact that their engagement had on the project and on their own personal development.

Results: The CONNECT project proved to be a tremendous learning experience for all those involved. Yet it was not without its learning curve, nor without its difficulties and growing pains. At the same time, this presentation will also show that the CONNECT project had many unanticipated outcomes which suggest that the full potential and transformative value of such collaborative enterprises has yet to be completely understood. When the name "CONNECT" was initially chosen for the project, it was meant to signify a paradigm shift in autism research by initiating a dialogue between autistic adults, service providers and policy makers. Indeed, when individuals living with autism reach adulthood, they are often "disconnected" from the various supports and services that were available to them during childhood. Yet as time passed and as the team reached its various milestones, the CONNECT name gradually took on a new meaning, bringing into more clearer focus the various human and personal "connections" that were being forged among autistic adults themselves. These connections were described by one Autistic patient partner as a form of "Autistic Oxygen." When reflecting on the significance of the data collected and especially on the value of their engagement in the CONNECT project as patient partners, another Autistic partner summed their experience this way: "We're the stakeholders with the most at stake."

Conclusions: The CONNECT project can be used as a prism through which one can see more clearly the myriad benefits and challenges of adopting a collaborative multi-stakeholder approach when studying adult autism, whether viewed from the perspective of the autistic community, the research community or the policy-maker and service-provider communities. In looking through the CONNECT experience lens, this presentation will offer practice-based recommendations for other teams that are considering using such an approach in their own research.

12 **233.012** Services for Family-Dependant Adults with Autism Spectrum Disorder, Why Some Are Received and Others Are Not

C. Jose[1], *P. D. George-Zwicker*[2], *J. Gaudet*[3], *M. Robichaud*[3], *M. J. Plourde*[3], *L. Tardif*[4] *and A. Bouma*[5], *(1)CFMNB, Maritime SPOR SUPPORT Unit, Moncton, NB, Canada, (2)Autistics Aloud, Autism Nova Scotia, Bedford, NS, Canada, (3)Maritime SPOR SUPPORT Unit, Moncton, NB, Canada, (4)Government of New Brunswick, Fredericton, NB, Canada, (5)BOUMA Woodworks, Woodstock, NB, Canada*

Background: Autism, a neurological difference is a large spectrum of conditions characterized by a variety of communication, sensory and social disabilities which lead to important challenges in day-to-day activities. While there has been an increased focus in providing early intervention programs for children with autism spectrum disorder (ASD), there remains a shortage of programs and services tailored to autistic adults with ASD, specifically to support employment and independence. The literature indicates that employment rates range between 4-49%, and as many as 70-80% are not living independently, with family members being the primary source of support and care.
Objectives: This research sought to determine priorities in terms of service needs for autistic adults with ASD living with family and examine factors influencing whether or not these services were being received.

Methods: This study included 104 respondents from the CONNECT project cohort (n = 164) who completed the needs assessment survey and lived with one or more family members: 41 self-reporting adults with ASD (aged 19-55 years) and 63 adults with ASD (aged 18-63 years) whose information was provided by their caregivers. Frequency distribution were calculated to examine service need priorities and reasons behind their lack of receipt. Logistic regression was used to examine which factors were associated with receiving priority services.

Results: The mean annual income of the respondents was $11,307, mainly originating from provincial government support and family. 56% of adults with ASD living with family members were unemployed and had a mean number of 1.96 co-occurring mental health or neurodevelopmental conditions. The top service priorities endorsed by over 40% of the sample included employment counselling, housing/residential options, life skills training and provincial disability program. Despite being identified as top service priorities, these services were only being received by 1.9 to 37.5% of the sample. The most common reason for not receiving these services were lack of availability for all except the provincial disability program (not meeting criteria). Adults who perceived themselves as having good mental health had a higher likelihood of receiving life skills

training and individuals with intellectual disability were likelier to receive provincial disability program. Adults receiving government support to assist with accessing services were likelier to receive both life skills training and provincial disability.

Conclusions: Overall, the results of this study highlight the need for greater access to services that support employment and independence for adults with autism. Our results also suggest that achievable changes, such as increased mental health care services and offering more government support to assist with accessing services, could meaningfully improve the outlook for autistic adults with ASD seeking to live full and independent lives.

13 **233.013** The Influence of Psychiatric Diagnoses upon Social Engagement, Social Skills, Problem Behaviors, and Loneliness Among Young Adults

***N. E. Rosen**, Y. S. S. Lograsso, M. Jolliffe and E. A. Laugeson, Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background: Research suggests psychiatric disorders are common in those with autism spectrum disorder (ASD), with some estimates revealing 70% of individuals with ASD have at least one comorbid diagnosis, and 41% have two or more (Simonoff 2008). These comorbidities often include attention-deficit/hyperactivity disorder (ADHD) (30-50%) and anxiety disorders (25-55%) (Leyfer 2006). While many of these individuals experience impaired social functioning as a consequence of their disorders, including poor social engagement, problem behaviors, and loneliness, little is known about the differences in symptom profile across these diagnostic groups.

Objectives: This study examines the influence of psychiatric diagnoses upon social engagement, social skills, problem behaviors, and loneliness among young adults with ASD, ADHD, and/or anxiety.

Methods: Participants included 165 young adults (74.5% male; mean age=22.44; *SD*=3.88) with ASD, ADHD, anxiety, or no diagnosis, presenting for social skills treatment through the UCLA PEERS® Clinic. 80 participants met clinical criteria for ASD and anxiety (ASD+ANX; 48.5%), 27 for ASD, anxiety, and ADHD (ASD+ANX+ADHD; 16.4%), 6 for ASD and ADHD (ASD+ADHD; 3.6%), 23 for ASD with no comorbidities (ASD; 13.9%), 20 for anxiety with no comorbidities (ANX; 12.1%), and 9 who did not meet clinical criteria for a developmental or psychiatric condition (NO DX; 5.5%). Diagnoses were assessed using caregiver-reports on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino 2012) for ASD, the Swanson, Nolan, and Pelham Questionnaire-4th Edition (SNAP-IV; Bussing 2008) for ADHD, and the Social Anxiety Scale (SAS; La Greca 1999) for anxiety. Young adults completed the Social Skills Improvement System (SSIS; Gresham 2008) to measure overall social skills and problem behaviors, Quality of Socialization Questionnaire (QSQ; Laugeson 2010) to assess frequency of social engagement, and Social and Emotional Loneliness Scale for Adults (SELSA; DiTommaso 1993) to measure social loneliness and overall loneliness.

Results: One-way ANOVAs and post-hoc Tukey Tests revealed significant differences between groups related to social skills [$F(5, 153)=17.11$, $p=.01$] on the SSIS, suggesting that participants with ASD+ANX and ASD+ANX+ADHD demonstrate the greatest impairment in overall social skills across the six groups. Analyses further revealed significant differences between these two groups related to problem behaviors [$F(5,155)=13.23$, $p=.01$] on the SSIS, revealing that those with ASD+ANX and ASD+ANX+ADHD exhibit the highest levels of problem behaviors. Interestingly, Tukey Tests revealed young adults with ASD+ADHD presented with average levels of social skills, but the highest levels of problem behaviors ($p=.01$). Participants with ASD and no comorbidities presented with average levels of social skills and the lowest levels of problem behaviors, while those with anxiety only and those with no diagnosis presented with the least impairment in social skills and problem behaviors ($p=.01$). No significant differences were observed between groups related to social loneliness [$F(5,146)=2.43$, $p=.04$] and overall loneliness [$F(5,145)=2.22$, $p=.05$] on the SELSA, or frequency of social engagement [$F(5,147)=.83$, $p=.53$] on the QSQ.

Conclusions: Results suggest that diagnostic groups significantly differ in levels of social skills and problem behaviors, with individuals with ASD and comorbid anxiety (sometimes in combination with ADHD) having the poorest social profile. These findings may provide useful information for delivering targeted interventions with these vulnerable populations.

14 **233.014** The Influence of Socioeconomic Position on Vocational Rehabilitation Service Utilization and Outcomes of Transition-Age Young Adults with Autism

***A. Roux**[1], J. Rast[2], K. Anderson[3], T. Garfield[1] and P. Shattuck[2], (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: In the United States, the Vocational Rehabilitation (VR) program closes cases for approximately 19,000 transition-age youth and young adults with autism spectrum disorder (ASD) annually who apply for VR services are found eligible. The federal VR program provides grants to states to help individuals with disabilities find, maintain, or regain employment. Generally, about 70% of youth and young adults with ASD who are eligible for VR services receive them, and about 60% of service recipients are employed at VR exit. Disparities in who receives VR services, and who achieves employment, are understudied.

Objectives: We explored whether factors of socioeconomic position (e.g., race, ethnicity, public benefits use, education level) predict receipt of VR services, timely development of individual plans for employment services, and employment outcomes among young adults with ASD.

Methods: We analyzed VR service utilization and employment outcomes for 14,319 young adults with autism (ages 18-24) in the federal Rehabilitation Services Administration (RSA) database who had a VR case that closed in FFY 2016. We used binary analyses and logistic regression to examine the association of race and ethnicity, financial disadvantage, and education on VR service use and outcomes.

Results: Young adults with ASD in the RSA dataset were primarily male (82.7%), White (75%), receiving financial support from family and friends (68.6%), and had a "most significant" level of disability (71.2%). Fewer were non-Hispanic Black (10.9%), Hispanic (8.4%), or recipients of supplemental security income (SSI) benefits at the time of VR application (34.9%). Young adults with ASD were significantly less likely to receive VR services if they were other/multiple races and non-Hispanic (OR=0.81), Hispanic (OR=0.84) (compared to non-Hispanic White young adults), or if they had public health insurance (OR=0.71) or no insurance (OR=0.85) (compared to having any private insurance). They were slightly more likely to receive VR services if they were SSI beneficiaries (OR=1.1) compared to those who were not. Young adults with ASD were significantly more likely to experience timely development of an employment plan with each year increase in age (OR=1.18) and if they were Hispanic (OR=1.26), but less likely if they were SSI beneficiaries (OR=0.75). Young adults with ASD were significantly less likely to be employed at VR exit if they were female (OR=0.79), SSI beneficiaries (OR=0.77), or if they had public health insurance (OR=0.73) or no insurance (OR=0.71) (compared to any private

insurance). They were slightly more likely to be employed at exit with each year increase in age (OR=1.11) or if they had any post-high school education (OR=1.22).

Conclusions:

We found significant differences in VR service utilization, timely development of employment plans, and successful employment following VR services based on several aspects of socioeconomic position including race, ethnicity, education level, receipt of public benefits and type of health insurance, in addition to gender. Reducing socioeconomic disparities is a stated priority in the 2017 federal plan for autism research. Results speak to the importance of recognizing the potential impacts of socioeconomic disadvantage on variation in VR program performance at the local, state, and national levels.

15 **233.015** The Reality of Executive Function Difficulties for Autistic Adolescents: Personal and Parental Perspectives

L. Kenny[1], *A. Remington*[2] *and E. Pellicano*[3], *(1)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (2)UCL Centre for Research in Autism and Education, London, United Kingdom, (3)Macquarie University, Sydney, Australia*

Background: The executive function (EF) abilities of autistic people have been extensively researched. Nevertheless, our ability to know whether these difficulties are relevant to the lives of young autistic people remains limited by the methodologies hitherto applied in EF research. Specifically, the voices of young autistic people are completely absent from the literature pertaining to EF in autism.
Objectives: The current study sought to directly examine the views and experiences of autistic adolescents and their parents towards their executive skills. It also sought to understand the perceived consequences of any EF difficulties and whether autistic young people conceive of their EF difficulties as related to being autistic or not.

Methods: Eleven autistic adolescents (11 male, 1 female), aged 12 - 19 years, and eight of their parents (all mothers) participated in separate, semi-structured interviews. Participants were asked several open-ended questions about their perceptions of their own/their children's EF abilities, with a focus on their higher order abilities, such as the ability to manage their time, to multitask, to retain information and to adapt flexibly to changes in task demands. Transcripts were analysed using Thematic Analysis from an inductive (bottom-up) perspective where themes were created within a 'contextualist' framework of critical realism.

Results: A central theme identified in the data was that EF is dependent on contextual and motivational factors and so is not fixed. While parents tended to laud their children's increased desire for independence, they were also acutely aware that with increasing age, the societal expectations placed on their children continue to change and parents often worried that increasing societal expectations outpaced their child's developments in EF. Young autistic people were often very accepting of their cognitive differences, simply reflecting on them as intrinsic aspects of who they are. Finally, the young people interviewed acknowledged that they drew heavily on the support of family and friends, who often provided an external locus of EF, and they highlighted that there was often a mismatch between the supports and accommodations they were offered and the types of executive difficulties they experienced.

Conclusions: The insights from this study could help redress the research and practice gap that currently exists about EF in autism. Specifically, in future, EF and autism researchers should; (i) develop assessments that tap the specific difficulties described by autistic people (e.g., getting started on a task or decoding multi-step instructions), (ii) measure performance on an assessment *and* measure the contextual factors like motivation and anxiety that are likely implicated in performance and (iii) be sensitive toward those who do not want support or interventions that might change their cognitions, and in turn, change their identity. On a broader scale, the current study demonstrated the value of supplementing positivist research into the cognitive processes of autistic people with phenomenological methods, not only to better understand the lived experience of those we study, but also to facilitate the development of an evidence base that more accurately captures these experiences and, as a result, better serves autistic people's needs.

16 **233.016** The Relation between Motor Abilities, Adaptive Behavior, and Quality of Life: A Study of Middle-Aged Adults with ASD

P. S. Powell[1], *A. T. Meyer*[2], *J. L. Mussey*[3], *M. R. Klinger*[4] *and L. G. Klinger*[5], *(1)School of Psychology, Georgia Institute of Technology, Atlanta, GA, (2)JFK Partners, University of Colorado School of Medicine, Aurora, CO, (3)UNC, Greensboro, NC, (4)UNC TEACCH Autism Program, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background:

Emerging evidence suggests motor skill deficits are a cardinal feature of ASD and reliably predict other ASD-related difficulties in cognitive functioning and adaptive behavior (MacDonald et al., 2015; Travers et al., 2017). However, few studies have examined motor-related difficulties in later adulthood and their relation to adult outcomes.

Objectives:

To assess motor abilities in middle-aged adults with ASD, and examine the relation between motor performance, adaptive behavior (e.g., daily living skills), and quality of life (QoL).

Methods:

Participants were 55 adults with ASD in mid-adulthood (27-57 years of age, M=37 years) who had previously participated in a larger study of adult outcomes (e.g., employment, education, QoL). All adults were diagnosed with an ASD during childhood (M=6 years). Participants completed a comprehensive in-person assessment including diagnostic (ADOS-2 and CARS-2), intellectual functioning (Stanford-Binet-5), adaptive behavior (VABS-II, Waisman ADL), and motor ability [grip strength (GS), finger tapping test (FTT), D-KEFS Motor Speed, Timed-up-and-go (TUG)]. Childhood assessment data from the Vineland Adaptive Behavior Scale (VABS) was also available and used as a covariate in the analyses. Three participants were unable to complete the motor measures and dropped from analyses.

Results:

Examination of motor performance revealed similar GS (M=51.6,SD=19.6) and FTT (M=47.1,SD=15.3) between dominant and non-dominant hands (p's≥.06). Average completion time (seconds) for D-KEFS Motor Speed and TUG test was 62.5s (SD=45.2) and 10.63s (SD=3.0), respectively. Across tasks, motor functioning was substantially below what would be expected for individuals without ASD and similar intellectual functioning (Cuesta-Vargas & Hilgenkamp, 2015). FTT, TUG, and GS were significantly correlated with adaptive behavior (r's ≥ .43, p's < .03), however only FTT and GS

correlated with QoL (r's ≥ .27, p's < .05). Motor Speed was not significantly correlated with the adult outcome measures (r's < .21, p's > .29). To assess the relation between motor functioning, adaptive behavior, and QoL, separate hierarchical linear regressions were conducted for each motor measure by first entering the adult with ASD's age, symptom severity (CARS-2), IQ, childhood VABS as covariates, followed by motor performance. Results indicated that of the four motor measures only FTT remained a significant predictor of adaptive behavior and QoL after controlling for the above mention variables (VABS-II: R^2=.06, β=.26,p=.04; Waisman ADL: R^2=.12, β=.38,p=.02; QoL: R^2=.23, β=.53,p=.003). Similar findings were also observed for the VABS-II subscales.

Conclusions:

Relative to published norms, the current findings suggest this middle-aged cohort of adults with ASD exhibit sub-optimal performance across a range of motor-related tasks. While GS and FTT were among the strongest motor abilities related to adaptive behavior and QoL, only finger tapping speed remained a significant predictor after controlling for age, IQ, ASD symptom severity, and childhood adaptive behavior. These findings document the important role of fine motor ability in predicting real-world outcomes in middle-aged adults with ASD. In light of emerging evidence suggesting poor adult outcomes in ASD, these findings point to specific motor abilities that could to be targeted in interventions to maintain, or possibly improve functional autonomy and quality of life in this aging population.

17 **233.017** Using Amazon's Mechanical Turk to Recruit Transition Age Adults with Autism

J. A. Findley[1], *V. Hang*[2], *J. H. McGrew*[3] *and L. A. Ruble*[2], *(1)University of Kentucky, Burlington, KY, (2)University of Kentucky, Lexington, KY, (3)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN*

Background:

Amazon's Mechanical Turk (MTurk) has been described as comparable to other online platforms and in person laboratory studies within the social sciences and for clinical psychology (Thomas & Clifford, 2017). However, researchers have recently reported a decline in data quality on MTurk due to the use of Virtual Private Servers (VPS) which allow participants to circumvent traditional screening methods that allow the researcher some control over participant recruitment (Dennis, Goodson, & Pearson, 2018). Further, the use of MTurk in clinical populations has led to demographic deception (i.e., misrepresentation of personal characteristics for eligibility requirements) which can result in incorrect conclusions drawn from the data (Chandler & Paolacci, 2017; Kan & Drummey, 2018).

Objectives:

We examined issues related to MTurk and asked the following: What percentage of participant attempts in a survey of daily living activities are usable in a clinical sample of caregivers or individuals with a self-reported ASD diagnosis aged 18-22? What are the most common reasons for non-payment (i.e., failed to meet study eligibility)? What are qualitative and quantitative differences in responses from VPS-respondents and non-VPS respondents?

Methods:

Participants were 370 individuals with a self-reported ASD diagnosis aged 18-22 years or their caregivers recruited via MTurk to answer questions about daily activities. Several screening questions (e.g., Individualized Education Program in school, formal diagnosis of ASD) designed to filter out ineligible participants were included. Once filtered, these participants were sent to the end of survey without payment. Further, additional questions were asked in multiple formats (e.g., age) to ensure eligibility (e.g., are you 18-22, what year were you born, how old are you?). Last, qualitative responses comparing respondents from VPS participants versus traditional internet providers were analyzed.

Results:

Out of 604 total attempts (including participants who attempted the survey multiple times), 39 were deemed usable leading to a 6.5% return rate. On average, participants responding from VPS servers attempted the survey four times while non-VPS participants attempted the survey two times. The most frequent reason for non-payment was failure to meet demographic criteria (e.g., out of age range, additional sensory diagnoses) and multiple attempts with inconsistent responses. Over fifty percent of response attempts were deemed unusable within the first seven demographic questions. Twenty percent of non-VPS respondents reported having an ASD diagnosis in one version of the survey and then reporting they did not have an ASD diagnosis in a different version, indicating participants switch their answers to meet inclusion criteria. VPS respondents use less words and nonsensical short answer responses when given open ended questions (see Table 1 for an example).

Conclusions:

Despite the inclusion of several screening criteria, usable return rates were low with demographic deception occurring at high percentages. Thus, research conclusions based on MTurk samples should be interpreted with caution as traditional screening methods may not be adequate for screening out low quality or invalid responses. Consistent with previous recommendations, open-ended responses within surveys can assist in flagging problematic responses (Dennis, Goodson, & Pearson, 2018).

18 **233.018** Validity of Subcategories of Repetitive Behaviors in Adolescents and Adults with ASD.

C. R. McDermott[1] *and V. Bal*[2], *(1)Neuroscience & Cell Biology, Rutgers University-New Brunswick, Piscataway, NJ, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ*

Background: Restricted and repetitive behaviors (RRBs) are core features of ASD. Previous studies have suggested two domains of RRBs measured by the Autism Diagnostic Interview-Revised (ADI-R): Repetitive Sensory Motor (RSM) and Insistence on Sameness (IS; e.g., Cuccaro et al., 2003). Bishop and colleagues (2013) demonstrated convergent validity of these domains with the Repetitive Behavior Scale-Revised (RBS-R) in a sample of school-age children. Consistent with previous studies, IS on both instruments were not significantly associated with IQ. A third domain, Circumscribed Interests, was positively correlated with IS, but showed differential associations with IQ across instruments. Studies have not yet considered the validity of RRB subcategories specifically in older adolescents or young adults. There is some evidence that broad domains of RRBs may change with age (e.g., Lord et al., 2015), suggesting a need to understand whether the constructs defined in children are valid in older samples.

Objectives: To investigate the construct validity of subcategories of RRBs measured by the ADI-R and RBS-R in adolescents and young adults.

Methods: Participants were 544 adolescents and adults (M age= 15.73, SD=2.40 years) selected from existing samples of research-referrals with

ADI-R, RBS-R and NVIQ data. RSM and IS domains were computed for each instrument; circumscribed interests (ADI-interests) was omitted from ADI-IS to allow for separate analysis (Bishop et al., 2013). Pearson correlations between measures and domains were examined in the overall sample and by age (13-15, 16-17 and 18+; Figure 1).

Results: There were significant (p<.001) associations between ADI-RSM and ADI-IS (r=.28) and ADI-IS and ADI-interests (r=.22), but not ADI-RSM and ADI-interests. When divided by age, the ADI-IS:ADI-interests correlation was comparable for 13-15-year-olds, but not significant for the older groups. In the overall sample, NVIQ was negatively correlated with ADI-RSM (*r*=-.44) and positively correlated with ADI-interests (*r*=0.30), but NVIQ:ADI-IS association was not significant. When divided by age, ADI-RSM:NVIQ associations were nonsignificant in adults.

Significant correlations were also observed for RBSR-RSM:RBSR-IS (*r*=.33) and RBSR-IS:RBSR-interests (r=.57); associations were comparable for all age groups. In contrast to the ADI-R, RBSR-RSM and RBSR-interests were moderately correlated (r=.33). Correlations were comparable in adolescents and strong for adults. Neither RBSR-IS or RBSR-interests were correlated with NVIQ. RBSR-RSM showed a moderate negative association with NVIQ for both adolescent groups, but not adults.

Associations between measures were moderate-to-strong for IS and RSM across all age groups; interests exceeded .3 for only the 18+ group. Significantly fewer adults than children were rated as having circumscribed interests reported on the ADI-R (X^2=9.02, p<.05); rates did not differ on the RBS-R.

Conclusions: Consistent with previous studies of school-age children, RSM and IS subscales on the ADI-R and RBS-R demonstrate reasonable convergent validity in adolescents and adults, though the relationship between circumscribed interests and IQ differed across instruments. Preliminary analyses suggest that, for adults, RSM behaviors may not be associated with IQ and the ADI-R may underestimate circumscribed interests. Data from an additional 56 adults will be integrated; confirmatory factor analyses and further investigation of possible differences in the manifestation of RRBs in adults will be conducted.

19 **233.019** What We Can Learn from Adult Self-Report Versions of Parent-Report Measures: Results of a Pilot Study

E. T. Crehan[1,2], *O. Ward*[1] *and R. R. Althoff*[3], *(1)Eliot-Pearson Department of Child Study & Human Development, Tufts University, Medford, MA, (2)Department of Psychiatry, AARTS Center, Rush University Medical Center, Chicago, IL, (3)Departments of Psychiatry, Pediatrics, and Psychology, University of Vermont College of Medicine, Burlington, MA*

Background:

Self-report measures allow researchers and clinicians to hear directly from individuals about their strengths and concerns. However, the development of self-report measures often involves simply switching the perspective of the question (e.g., from "How often does your child..." to "How often do you...") without assessing whether responses capture the same phenomenon as the parent report. Previous work has shown inconsistencies between parent- and self-report (Robinson et al., 2018). In this pilot study, we explore this effect in autism-specific and general self-report measures in a group of adults.

Objectives:

Illustrate how adult self-report measures coincide with previous work with parent-report measures and younger populations

Methods:

We recruited 32 adults (14 with a diagnosis of autism,18 without). Participants completed a social responsiveness scale (SRS-2-SR, Constantino, 2012), Theory of Mind Inventory (ToMI; Hutchins, Prelock, & Bonazinga, 2012), Liebowitz social anxiety screener (LSAS; Fresco et al., 2001), adaptive scales from the Adult Self-Report (Achenbach & Rescorla, 2003), eye tracking paradigms, and a brief IQ screener (WASI; Wechsler, 1999). Self-report scores were compared by diagnosis and correlations among self-report measures were explored.

Results:

Complete data were available on 30 participants. Predicted significant group differences emerged between the autistic and non-autistic groups on the autism-specific measures, with the autistic group reporting lower scores on the advanced ToMI scale t(30) = 3.636, *p*=.001 and four of the SRS subscales; cognition t(15.421) = -3.302, *p*=.005, communication t(30) = -4.209, *p*<.001, motivation t(30) = -3.847, *p*=.001, and autistic mannerisms t(15.133) = -4.544, *p*<.001.The autistic group scored significantly higher on the LSAS Fear/Anxiety scale t(30) = -2.321 p = .027. On the ASR adaptive scales, the autistic group demonstrated significantly lower scores on the family t(28) = 2.73, p = 0.011 and friends scales t(28) = 2.094, p = .045.

Exploratory correlations between self-report measures showed that SRS motivation was significantly correlated with early Theory of Mind (*r*= -.499 p<.005) and SRS Communication was significant at the trend level (*r*= -.476, p = .006). Early ToMI was significantly correlated with LSAS Avoidance (*r* = -.526, p<.005).

Conclusions:

The use of self-report measures is critical to focus research on the needs and wants of a studied population. Particularly in the study of autism and developmental disabilities, incorporating the perspectives of impacted individuals has not consistently been a research priority. We must develop strong methodological approaches to reflects the interests of autistic adults. Even in this small sample, our data show similar group differences on autism-specific measures as observed in parent-report measures. Exploratory correlations reflect trends from studies in younger samples. For instance, although the effect is smaller, the pattern of correlations between ToM and social responsiveness is similar in shape to the pattern shown in childhood (Lei & Ventola, 2018). Consistent with our findings, the relation between ToM and later social functioning has seemed weak in other studies using parent-report (Bennett et al., 2013).Next steps include directly comparing parent- and self-report measures in an adult population to illustrate what information is being missed by relying solely on parent report.

20 **233.020** Women and Social Communication Abilities

W. Mitchell[1] *and D. B. Nicholas*[2], *(1)Sinneave Family Foundation, Calgary, AB, Canada, (2)University of Calgary, Edmonton, AB, Canada*

Background:

The ability to communicate effectively is highly valued by employers and there is growing evidence that women with ASD and average intelligence present with better social communication skills than their male equivalents which may positively influence employability for women.

Employment*Works* Canada (EWC), a national employment preparation program for young adults with ASD that is embedded within the community,

is gathering practice based evidence about social communicative abilities using the Communication Checklist – Adult (CC-A). The CC-A is an informant questionnaire that measures structural language abilities (speech, syntax and semantics), pragmatic skills (matching language to context), and social engagement. It provides information regarding one's use of language from an informant's perspective derived from daily interactions with the individual.

Objectives:

1. Are the EWC participants' scores on the CC-A comparable to the CC-A normative sample of individuals with ASD (not in an employment cohort)?
2. Do EWC participants' scores on the CC-A differ based on gender?

Methods:

Secondary data analysis was conducted using the CC-A normative sample (n=55) and 147 EWC participants who completed the CC-A as a baseline measure for EWC.

Results:

An independent t-test was conducted to compare the scaled scores of EWC participants to the CC-A normative sample. The CC-A normative sample had significantly lower Language Structure scaled scores, t (205) = 2.14, p =.034, d =0.38; as well as lower Pragmatic skills scaled scores, t (205) = 2.15, p =.033, d =0.39, compared to all of the participants from Canada.

Because the CC-A normative sample only had one female and there is some evidence that women with autism may present with better social communication skills the participants from EWC were grouped according to gender. Of importance, independent samples *t*-tests and Chi-square tests (p>.05) indicated the female and male participants in EWC were similar in age, educational attainment, understanding of single word vocabulary and reported severity of autistic symptoms as measured by the Social Responsiveness Scale-2. A comparison of the female EWC participants, male EWC participants, and CC-A mixed normative sample using a one-way ANOVA was conducted. There was a statistically significant main effect for group on the Language Structure domain, [F (2, 199) = 5.84, p = .003]. Post-hoc tests (Table 1) revealed the female EWC participants scored significantly higher than participants from the CC-A normative group and the male EWC participants. No significant difference were noted between the CC-A normative sample and male EWC participants.

Conclusions:

Although the female EWC participants had significantly better structural language skills than the male EWC participants and the CC-A normative sample, their low pragmatic skills scores are consistent with an autism profile derived from the CC-A. Likewise, their communicative difficulties, having two or more scaled scores of 6 or less, will have an impact on everyday life. These findings raise provocative questions about assumptions about gender-mediated differences, and invite critical reflection on social interaction challenges for females and males with ASD in the workplace.

21 **233.021** Women with ASD: Outcomes of a Pre-Employment Program

W. Mitchell[1] *and D. B. Nicholas*[2]*, (1)Sinneave Family Foundation, Calgary, AB, Canada, (2)University of Calgary, Edmonton, AB, Canada*

Background:

Current research on women with autism spectrum disorders (ASD) and employment success is lacking. To date, studies that have reported on predictors of employment and gender have been mixed. Employment*Works* Canada (EWC), a national program embedded within the community, is gathering practice based evidence in relation to gender and employment.

Objectives:

To compare the employment outcomes of young women and men with ASD following participation in EWC, an employment preparedness training and experiential community-based job sampling program, and to capture the lived experiences of the young women.

Methods:

Data was extracted from the application or baseline measures and employment rates were derived from follow-up phone calls with participants. Phone interviews were completed with 10 young women following participation in the EWC program.

Results:

Participants (n=262) from 9 provinces across Canada completed the EWC program; 76% (n=199) were men and 24% (n=63) were women. The men and women were comparable on a number of personal factors; age, educational attainment, minority representation, understanding of single word vocabulary (a proxy for Verbal IQ) as measured by the Peabody Picture Vocabulary Test - Fourth Edition (PPVT-4), reported severity of autistic symptoms based on the Social Responsiveness Scale - 2 (SRS-2), independence in activities of daily living as measured by the Waisman – Activities of Daily Living (W-ADL), independence of transportation, and previous work history (Table 1).

Differences were noted in relation to age of diagnosis and co-existence of mental health concerns (Table 1). Significantly more women (46%) received a diagnosis in adolescence or adulthood compared to men (29%). Women were more likely to have heightened experience related to depression (49%) and panic attacks (36%), than men (27% and 20% respectively).

Both men and women had similar employment rates at the beginning of the program but 3 months after completion, women were significantly more likely to have found a job with over half of the women indicating that they were employed (Figure 1).

Themes from follow-up interviews focused on challenges related to receiving a diagnosis later in life and limited awareness about women with ASD. Most participants stressed the importance of believing in oneself, the need for self-advocacy and connecting with others.

Conclusions:

For women in the program, the age of diagnosis and identified depression or panic attacks did not negate post-program employment.

22 **233.022** "I Was Exhausted Trying to Figure It out": The Experiences of Females Receiving an Autism Diagnosis in Middle Adulthood

M. Freeth[1]*, A. Leedham*[2] *and A. Thompson*[2]*, (1)Psychology Department, University of Sheffield, Sheffield, United Kingdom, (2)Psychology, University*

of Sheffield, Sheffield, United Kingdom

Background: Females often receive Autism Spectrum Condition (ASC) diagnoses later than males, and their experience may differ in a number of ways as a result of this and gender related issues. Whilst the prevalence of autism diagnosis in females in middle adulthood is increasing there is little understanding of their lived experiences.
Objectives: To investigate the lived experiences of female adults diagnosed with an ASC in middle adulthood.

Methods: Participants were females (n=11) who received an ASC diagnosis in the UK, over the age of 40 years. Participant mean age at diagnosis was 47 years (range 40-62 years); mean current age was 51 years (range 43-64 years). In-depth semi-structured interviews with each participant were analysed using Interpretative Phenomenological Analysis (IPA).

Results: Four super-ordinate themes emerged: The hidden nature of ASC in females (pretending to be normal and fitting in; mental health and mislabelling); the process of acceptance (initial reactions and search for understanding; re-living life through a new lens; grief and reflections on the past); the impact of others post-diagnosis (initial reactions; stereotyped assumptions); a new identity on the autism spectrum (negotiating relationships, connections and community; changing well-being and views of the self; the meaning of diagnosis).

Conclusions: Several common factors affect the experience of late diagnosis in females, including the widespread limited understanding of others. The process of diagnosis tended to be experienced as facilitating transition from being self-critical to self-compassionate. Participants experienced a change in identity that enabled greater acceptance and understanding of the self. However, this was painful to adjust to at such a late stage. Recommendations to practitioners are that strategies to conceal features of ASC should be considered at assessment; autistic-led training of service providers to support earlier recognition is needed; females should be assessed by skilled clinicians who are able to approach the diagnostic process critically.

23 **233.023** "Reasons I Interact with the Outside World": Motivations and Barriers to Community Engagement and Social Interaction in Adults on the Autism Spectrum

T. A. M. McDonald[1]*, Z. J. Williams*[2]*, M. Harden*[3]*, F. Ye*[4]*, R. Fan*[4] *and B. A. Malow*[1]*, (1)Sleep Disorders Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, (2)Medical Scientist Training Program, Vanderbilt University School of Medicine, Nashville, TN, (3)Department of Neurology, Sleep Disorders Division, Vanderbilt University Medical Center, Nashville, TN, (4)Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN*

Background:
As children with autism age into adolescence and adulthood, their social environment becomes increasingly more complex, yet the number of programs, services, and interventions (PSIs) available to them dramatically decrease. Compared to interventions for children with autism, there are relatively few interventions targeting skill development and engagement for adults with autism. Although the literature investigating the perceptions, experiences, and values of adults with autism is growing, the current literature base is still sparse and remains a priority for research. Understanding the perspectives of adults on the autism spectrum is critical for developing meaningful PSIs for this population.

Objectives:

To increase the social validity of PSIs for this population, this study sought to investigate the self-reported life goals as well as the motivations and barriers to community engagement perceived by 42 adults on the autism spectrum.

Methods:

Participants (ages 18 – 34 years) completed an anonymous online survey that included multiple-choice, multiple-response items and open-ended items related to demographic questions, intervention history, interests, goals, and barriers to activities or social engagement. Open-ended items included: "Please list one or two of your most important goals", "What motivates you to engage in activities outside the home?", and "What motivates you to engage with others?" Qualitative analysis and inter-coder agreement of survey responses by multiple authors was performed.

Results:

Participants reported a wide range of goals, with common themes of employment/vocation and education/training, but also independence, relationships, health, humanitarian causes, emotions, character, and religious/spiritual domains. Participants also identified barriers to engagement in activities or social interactions related to social difficulties and desire, emotions, transportation, employment and financial affairs, health and sensory input, and scheduling, with the majority (80%) of adults identifying more than one barrier. Over 40% of respondents were not in employment, education, or training (NEET). Inter-coder agreement was high.

Conclusions:

While employment was regarded as a major goal, many other goals were identified by participants. A wide range of barriers were also identified. PSIs that serve adults on the autism spectrum should consider the wide range of goals and barriers to engagement identified by this population.

24 **233.024** Educational Achievements, Employment and Future Plans for Autistic Individuals within a Population-Based Twin Sample.

V. L. Milner*, E. Colvert and F. Happé, Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
Previous research has shown a large proportion of adults with ASD (diagnosed in childhood) were not living independently, were unemployed and left school without formal academic qualifications. Past studies primarily focus on clinical samples which might not be representative. This study uses a population-based twin sample.

Objectives:

This study compared the education, employment and future plans for autistic individuals from a population-based twin sample, with those of their non-ASD co-twins and typically developing twins, measured by both self and parent-report questionnaires.

Methods:

Three groups of participants were included: 45 twins who met criteria for a research diagnosis of ASD (78% male; mean age 18 years 11 months); 24

non-ASD co-twins (33% male; mean age 18 years 11 months); 50 comparison twins (68% male; mean age 18 years 8 months). Parents of the twins were also invited to take part and three groups were included: 62 parents of ASD twins; 24 parents of non-ASD co-twins; and 56 parents of comparison twins. Parent- and twin-reports were independent, i.e. parents were not necessarily reporting on those twins who provided self-report data. Participants and their parents completed team-designed questions about education, employment and future plans as part of a wider research assessment.

Results:

The ASD group gained significantly fewer passes than the co-twin or comparison groups at GCSE (F=13.42, 2, p<.001), AS level (F=4.78, 2, p<.05) and A-level (F=8.21, 2, p<.001). The vast majority in all three sample groups were in post-16 education (96-98%) and planned to be in post-18 education (83-92%).

Parents and twins reported that the ASD group had fewer employment roles than the co-twin or comparison groups (parent-report: F=6.54, 2, p<.01; self-report: F=14.57, 2, p<.001). For the ASD group 20% of parents and 12% of twins reported requiring help in work, versus 0% of parents reporting on the co-twin or comparison groups, and only 9% of the co-twins by self-report (0% of comparison). For the ASD group the most frequently mentioned help was one-to-one support to keep on task.

The ASD twins were less likely to have considered what to do after leaving education, compared with the co-twin or comparison groups (parent-report: F=7.71, 2, p<.01; self-report: F=4.65, 2, p<.05). ASD young adults were also less likely to mention long-term relationships/marriage as something desirable in the future (parent-report: F=9.24, 2, p<.001; self-report: F=10.81, 2, p<.001). Parents rated ASD twins as less likely to want to live independently (F=6.60, 2, p<.01), but those ASD twins who provided self-report did not differ from the co-twin or comparison groups in terms of planning to live independently (F=2.94, 2, p=.06).

Conclusions:

ASD twins had fewer examination passes, employment roles and were less concerned about future planning and long-term relationships compared to co-twins and non-ASD comparison twins. For both parents and ASD twins, worries about the future in terms of independence and coping were evident.

25 **233.025** Understanding College-Specific and General Well-Being Students with and without ASD

***K. Casagrande**, K. M. Frost and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

Background: The transition to college is often marked by anxiety, depression, and isolation. This transition may be especially challenging for students with ASD, who already experience increased anxiety and depression, alongside reduced life satisfaction. The College Student Subjective Well-being Questionnaire (CSSWQ) was developed to measure four specific aspects of well-being among neurotypical college students: college gratitude, academic efficacy, satisfaction with academics, and school connectedness. The CSSWQ is related to academic and psychosocial outcomes above and beyond general measures of well-being. Given the unique social deficits of ASD and risk for poor academic outcomes, it is important to understand whether predictors of college well-being are similar between students with ASD and their neurotypical peers.
Objectives: To better understand college-specific and general well-being for college students with and without ASD by answering the following questions: 1) How does college-specific and general well-being in students with ASD compare to their neurotypical peers? 2) Is the relationship between domains of college well-being and overall well-being similar across groups? 3) How do social and academic experiences relate to domains of college well-being across groups?

Methods: College students with ASD (n=42, 67% male, 91% white, 21% first-generation) were recruited through disability resource centers at several degree-granting universities in the midwestern U.S. A matched comparison of neurotypical peers (n=50, 64% male, 86% White, 18% first-generation) were recruited through an undergraduate research pool. Both groups completed an online survey containing measures of autism symptomology (Autism Spectrum Quotient; AQ), college well-being (CSSWQ), and general well-being (Satisfaction With Life Scale; SWLS). Additional descriptive information about social and academic experiences was also collected, including perceived social support, preparation for academics and independent living, aspects of social participation, and GPA.

Results: Overall well-being did not differ significantly across groups ($F(1,90)=2.228$, $p=.139$, $\eta^2=.024$). On the CSSWQ, only the school connectedness subdomain ($F(1,90)=4.253$, $p=.042$, $\eta^2=.045$) was different between groups, such that students with ASD reproted lower levels of connectedness than their neurotypical peers (see Table 1). After controlling for demographics (age, gender, race, and first-generation student status), college-specific well-being ($\Delta R^2=.329$, p<.001), connectedness specifically ($\beta=.52$, p<.001), explained a significant amount of variance in general well-being over and above the effect of autism severity alone ($\Delta R^2=.072$, p=.006). The interaction between CSSWQ domains and autism symptom severity was also not significant ($\Delta R^2=.010$, p=.610). Exploratory correlations showed that connectedness was related to a variety of other predictors of well-being, such as social support and integration, whereas other domains of college well-being were not (see Table 2).

Conclusions: While the relationship between college well-being and a more general measure of well-being was similar across groups, individuals with ASD were less likely to report feeling connected with peers in college. Furthermore, that connectedness was highly related to overall well-being even after accounting for ASD symptom severity. Given the importance of the college social experience in both college and overall well-being, significant attention should be paid to the protective role of social support systems in addition to academic services when understanding how to support individuals with ASD in the college transition.

Poster Session
234 - Biomarkers (molecular, phenotypic, neurophysiological, etc)
11:30 AM - 1:30 PM - Room: 710

26 **234.026** Hypermasculinised Facial Structures in Brothers but Not Sisters of Autistic Children

***D. W. Tan**[1], M. T. Maybery[1], G. A. Alvares[2], A. J. Whitehouse[2], S. Z. Gilani[3] and A. Mian[3], (1)School of Psychological Science, University of Western Australia, Perth, Australia, (2)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (3)School of Computer Science and Software Engineering, University of Western Australia, Perth, Australia*

Background:
Autism spectrum disorder (ASD) is diagnosed approximately three times more frequently in males than in females. One biologically-driven hypothesis suggests that the male prevalence in ASD may be influenced by the exposure to elevated concentrations of testosterone during pregnancy. During fetal development, the brain and the face evolve from the neural crest in synchrony. This has led to the speculation that facial structures may hold crucial information to further our understanding of atypical neurodevelopment in ASD. A recent study reported hypermasculinised facial structures of autistic boys and girls when compared to non-autistic children (Tan et al., 2017, Scientific Reports).

Twin and family studies have provided clear evidence that certain cognitive phenotypes associated with ASD, such as social difficulties, are highly heritable. In terms of facial structures, several studies have found familial factors to explain more than 70% of structural variations in faces; of which, familial factors accounted for 49% of the variations in facial masculinity in particular.

Objectives:

The present study aims to investigate whether masculinised facial features are present in full siblings of autistic children using 3D photogrammetry.

Methods:

Twenty-three boys (mean age=7.31 yrs, SD = 2.68) and 20 girls (mean age=6.95 yrs, SD = 2.76) who are non-autistic siblings of children with ASD were included in this study. Every sibling was age- and sex-matched with three typically-developing children without siblings with ASD (69 boys [mean age=7.39 yrs, SD = 2.51] and 60 girls [mean age=7.41 yrs, SD = 2.42]). Landmarks were placed on each 3D image to generate a set of linear and geodesic distances previously found to accurately differentiate between boys and girls of similar ages as those included in the current study. Using these distances, a continuous 'gender score' can be computed for each face to indicate the degree of facial masculinity. Behavioural information collected using Social Responsiveness Scale-2 (SRS-2) is available for 28 siblings (17 boys) and Children Communication Checklist-2 (CCC-2) is available for 24 siblings (14 boys).

Results:

Facial masculinity was significantly increased in the male siblings of autistic children compared to those of the male comparison group [$t(90) = 2.92$, $p = .004$, $d = .70$]. However, there was no difference in facial masculinity between female siblings and comparison group ($p = .67$). Using Spearman's rank correlation coefficient, we found that facial masculinity was unrelated to scores on SRS-2 and CCC-2 when boys and girls were analysed together and separately.

Conclusions:

Tan et al. (2017) reported hypermasculinised facial structures in both boys and girls with ASD relative to a comparison group of non-autistic children. The current study found that hypermasculinised facial features were present only in male siblings of autistic children but not in female siblings. This study suggests the possibility that facial masculinity associated with ASD may be heritable only in boys but not in girls.

27 **234.027** Identification of Neurotransmitter-Associated Metabotypes: Further Stratification of the Children's Autism Metabolome Project ASD Subjects.

E. Donley[1], *A. Smith*[2], *M. Ludwig*[2], *D. B. Sugden*[2], *L. Feuling*[2], *M. Natowicz*[3], *D. G. Amaral*[4] *and R. Burrier*[1], *(1)Stemina Biomarker Discovery, Madison, WI, (2)Stemina Biomarker Discovery, Inc., Madison, WI, (3)Pathology & Laboratory Medicine Institute, Cleveland Clinic, LL-3, Cleveland, OH, (4)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA*

Background: Autism spectrum disorder (ASD) is biologically and behaviorally heterogeneous and is associated with a diverse array of underlying genetic, metabolic, and environmental factors. We conducted the Children's Autism Metabolome Project (CAMP, ClinicalTrials.gov Identifier: NCT02548442) comprised of 1100 children to identify altered metabolism associated with ASD. Utilizing a metabotyping approach we created metabolic tests which identify subpopulations of ASD subjects. We recently published (Smith et al., 2018) Amino Acid Dysregulation Metabotypes (AADMs) associated with dysregulation of the amino acids (AA) glutamine, glycine, and ornithine in ratios with branched-chain amino acids (BCAAs). The AADMs were present in 17% of the CAMP subjects with ASD. Metabotype stratification of ASD may provide more biochemically homogenous populations that, in turn, offer the potential for more tailored pharmacological, behavioral, and dietary interventions.
Objectives: We sought to: 1) identify additional metabotypes described by plasma amine containing metabolites associated with neurotransmitters; 2) determine whether neurotransmitter-related metabotypes describe an independent population of ASD subjects that is additive to AADMs; and 3) optimize the inclusion of diagnostic metabotypes to create a battery of tests that increase overall diagnostic performance of the amine-based metabolic tests.

Methods:

The Autism Diagnostic Observations Schedule-Second Version (ADOS-2) was performed by research reliable clinicians to confirm ASD diagnoses. A training set of CAMP subjects (ASD=253, TYP=85) was utilized to identify metabotypes and create metabolic tests. The reproducibility of the tests was evaluated in an independent test set of CAMP subjects (ASD=263, TYP=79). Plasma samples from these subjects were analyzed using a quantitative mass spectrometry-based assay for amine containing metabolites. A heuristic algorithm was applied to the training set to identify biomarkers able to discriminate ASD subpopulations using a diagnostic threshold to define the subpopulation. The diagnostic thresholds were used to create panels of tests for metabotype populations and then the reproducibility of the metabotype was evaluated in the test set of subjects.

Results:

Reproducible metabotypes containing the neurotransmitter-associated metabolites kynurenine and glycine were identified in the training and test sets. The kynurenine-based metabotype also includes, ornithine, glutamic acid, and ethanolamine and identifies 8.5% of CAMP ASD subjects. The glycine-based metabotype also includes asparagine, phenylalanine, and lysine and identifies 12% of CAMP ASD subjects. Both neurotransmitter metabotypes identified ASD subjects with greater than 95% specificity. These additional metabotypes increased the overall diagnostic sensitivity from 17% defined solely by the AADMs to about 30% when all metabotypes are combined into the test battery.

Conclusions: Continued analysis of the CAMP study samples using metabotyping techniques has identified additional neurotransmitter-related metabotypes of ASD. Stratifying ASD based on metabotypes offers an opportunity to identify children earlier at risk for ASD as well as the

potential for targeting therapies based on the metabotypes for more precise and individualized treatment.

28 **234.028** Influence of Race and Ethnicity on Broader Autism Phenotype Ratings of Mothers and Fathers from the Simons Simplex Collection

R. K. Ramsey *and K. M. Walton, Nisonger Center, The Ohio State University, Columbus, OH*

Background: In simplex families, broader autism phenotype (BAP) traits tend to differ by parent sex and BAP measure (Davidson et al., 2012). Except for one study indicating no differences in BAP traits between minority and non-minority parents (Sasson et al., 2013), there are no studies analyzing BAP presentation across multiple races or ethnicity. Diagnostic rates of autism in children are shown to differ by race and ethnicity (Jo et al., 2015). Revealing similar differences in parent BAP traits may provide insight into the racial and ethnic disparities observed in the diagnosis of autism.

Objectives: This study examines whether BAP ratings of mothers and fathers of a child with autism differ by their race or ethnicity.

Methods: BAP traits were examined in 2,479 mothers (9.2% Hispanic, 4.5% Black, 5.6% Asian) and 2,516 fathers (8.1% Hispanic, 5.4% Black, 4.8% Asian) who had a single child with autism in the Simons Simplex Collection (SSC). BAP traits were measured using self-reports (Broader Autism Phenotype Questionnaire (BAPQ)), other parent ratings (Social Responsiveness Scale: Adult Research Version (SRS: ARV)), and clinical interviewer ratings (Family History Interview - Impressions of Interviewer (FHI-IoI)). BAP ratings of mothers and fathers were compared across ethnicity (Hispanic vs. Non-Hispanic) and race (White, Black, and Asian) for each measure.

Results: Regarding ethnicity, Hispanic mothers (*M*=32.89, *SD*=21.95, *n*=252) and fathers (*M*=33.24, *SD*=25.37, *n*=220) had significantly higher SRS ratings than Non-Hispanic mothers (*M*=29.28, *SD*=20.24, *n*=2,483) and fathers (*M*=29.51, *SD*=22.29, *n*=2506, *p*'s<.05). However, Non-Hispanic fathers had significantly higher BAPQ aloofness, overall BAPQ, and FHI-IoI ratings than Hispanic fathers (*p*'s<.05). Regarding race, Asian mothers (*M*=2.60, *SD*=.75, *n*=138) were significantly higher than White mothers (*M*=2.37, *SD*=.78, *n*=2210) on BAPQ aloofness (*p*=.003), while Black mothers (*M*=2.44, *SD*=.73, *n*=111) were not significantly different from either. White fathers had higher BAPQ domain and overall scores compared to Black fathers, while Asian fathers had significantly higher BAPQ pragmatic scores compared to Black fathers, but significantly lower BAPQ rigidity scores compared to White fathers (*p*'s<.05). Both Asian mothers and fathers were significantly less likely to have ASD traits based on the FHI-IoI compared to the other two groups (*p*'s<.05). While BAP ratings were generally correlated, the FHI-IoI was not correlated with other measures for mothers and fathers in the Hispanic and Asian groups (*p*'s>.05).

Conclusions: Overall, BAP trait differences were observed across race and ethnicity, which varied by measure. Generally, White fathers tended to have more BAP traits compared to others, which could be due to a higher prevalence of autistic traits in White males or an artifact of norming BAP measures on predominantly White male populations. Furthermore, other parents rated Hispanic parents higher on BAP traits, while clinical interviewers rated Hispanic and Asian parents lower. Such differences may be due to cultural biases in others' ratings or actual differences in BAP presentation by race and ethnicity. These findings caution against using a single measure to capture BAP traits (Davidson et al., 2012). More research is needed to determine whether current BAP measures accurately assess for traits in minorities.

29 **234.029** Interactions between the Hypothalamic-Pituitary-Adrenal Axis and Autonomic Nervous System As Predictors of Depressive Symptoms in Children with ASD

R. A. Muscatello[1]*, E. McGinn*[2]*, S. Ioannou*[2]*, J. Andujar*[3] *and B. A. Corbett*[2]*, (1)Neuroscience Graduate Program, Vanderbilt University, Nashville, TN, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt University, Nashville, TN*

Background: The hypothalamic-pituitary-adrenal (HPA) axis and autonomic nervous system (ANS) are physiological systems involved in arousal response and regulation, and independently, have been implicated in negative behavioral health outcomes, including internalizing disorders. Dysregulation of these systems has been reported in autism spectrum disorder (ASD), including elevated evening cortisol, as well as hyperarousal of the sympathetic (SNS) and under-responsivity of the parasympathetic (PNS) branches of the ANS. Previous research to identify associations with physiological dysregulation and internalizing symptoms in ASD has produced inconsistent findings, and little attention has been paid to the interactions of the distinct, yet interrelated, HPA axis and ANS.

Objectives: The current study examined differences in physiological regulation for 96 children 10-to-13 years of age with ASD (11.25 years) and typical development (TD; 11.24 years). Subsequently, interactions between the HPA axis, PNS, and SNS were examined within the ASD group. The extent to which the individual systems, as well as the interactions between them, predicted parent-reported internalizing symptoms in children with ASD was investigated.

Methods: In 96 children with ASD (N=64) and TD (N=32), diurnal rhythm of the HPA axis was measured via salivary cortisol, collected through passive drool at home over 3 days, collected in the morning (twice), afternoon, and evening. Baseline respiratory sinus arrhythmia (RSA) and pre-ejection period (PEP) were collected in the lab via electrocardiography and impedance cardiography to examine PNS and SNS regulation, respectively. Parents completed the Child Behavior Checklist (CBCL), and the Withdrawn/Depressed, Anxious, and Internalizing subscales were included in analyses. ANOVAs were used to compare group differences, and hierarchal multiple linear regression was used to examine the extent to which physiological variables and their interactions predict internalizing symptoms.

Results: Consistent with previous research, children with ASD showed elevated evening cortisol compared to TDs ($F(1,93)=11.77$, $p=0.001$). There were no significant group differences in baseline RSA or PEP (all $p>0.05$); however, the ASD group reported higher scores on CBCL subscales Withdrawn/Depressed ($t(94)=-7.51$, $p<0.001$), Internalizing ($t(94)=-8.50$, $p<0.001$), and Anxious ($t(94)=-5.44$, $p<0.001$). No significant main effects of physiological variables on CBCL subscales were seen using hierarchal linear regression while controlling for age, IQ and gender (all $p>0.05$). However, in the next step of the model, controlling for demographics and main effects, there was a significant interaction for cortisol and RSA, which accounted for 9% of the unique variance in CBCL Withdrawn/Depressed symptoms in ASD ($\Delta F(1,42)=5.51$, $p=0.03$). Posthoc analysis revealed that ASD participants with low evening cortisol showed a negative trend association between RSA and withdrawn symptoms ($t(92)=-1.89$, $p=0.06$).

Conclusions: The results extend previous findings on physiological dysregulation in ASD to reveal the presence of unique interactions, which predict parent-reported symptoms of depression. Children with high PNS regulation and low evening cortisol showed the fewest symptoms. In contrast, hyper-arousal in the HPA axis and/or PNS was associated with elevated depressive symptoms, even in the presence of more adaptive physiological regulation in the other system. The findings underscore the importance of examining arousal across multiple systems to more

accurately identify response profiles associated with behavioral outcomes in ASD.

30 **234.030** Inverted Faces: An Indicator to Identify ASD and TD

***L. Shen**, X. He and X. Gao, School of Medicine, Tsinghua University, Beijing, China*

Background: Eye tracking technique is widely used to assist in identifying ASD due to its non-invasive and comfortable characteristic. When seeing a normal human face, ASD and TD children show big different interests, especially in eyes and mouths. Inverted human faces are interesting stimulus that cause human brain having different response than normal faces. But there's no experiment to show whether responses to inverted faces can be an indicator to identify ASD and TD.

Objectives: Our goal is to investigate whether there are significant differences between ASD and TD children on their response to inverted faces, and to set up a model identifying ASD and TD.

Methods: The experiment used SMI desktop eye tracking system with frequency 250Hz. It was designed to have 12 pictures of human faces in same size and luminance with different gender and ages. Starting with a 10 second black picture, then 9 pictures were showed continuously with 2 seconds on each, and last 3 pictures with 4 seconds on each. In the series, the 3^{rd} ,7^{th}, 10^{th}, 11^{th} ,12^{th} pictures were inverted faces. Fixation time on Area of Interest (AOI) of eyes, mouths, and faces were collected, as well as pupillary data. Data were analyzed later by SPSS and MATLAB.

Total 25 subjects of 3-6 years old children with 11 ASD and 14 TD provided valid data on this experiment. ASD children had diagnosis from hospital and double checked by CARS (Child Autism Rate Scale).

Results: Based on the experimental data, 13 factors were extracted, and 5 of them showed significant difference for ASD and TD group. Principal Component Analysis showed that 3 of these factors were critical. Naive Bayes Classifier was constructed with these 3 critical factors, and its performance was evaluated by leave-one-out method. The model gave a result of an accuracy of 88.0% and an AUC of 92.2% on its prediction.

Conclusions: Eye responses on inverted faces is a sensitive indicator to identify ASD and TD. It can be used to build up a model to assist in ASD screening on 3-6 years old children.

31 **234.031** Itarget-Autism Initiative: A Guiding Look into the Microbiome Profile in Autism Spectrum Disorders

***S. Redmond**[1], K. Calli[2], H. MacRitchie[1], E. Rajcan-Separovic[2], W. Mohn[3] and M. S. Lewis[2], (1)Department of Medical Genetics, Children's and Women's Health Centre of BC, University of British Columbia, Vancouver, BC, Canada, (2)University of British Columbia, Vancouver, BC, Canada, (3)Department of Microbiology and Immunology, Life Sciences Institute, University of British Columbia, Vancouver, BC, Canada*

Background:
Autism Spectrum Disorders (ASD) are complex neurodevelopmental conditions comprised of deficits in communication, social reciprocity and patterns of restrictive behaviours with preservative interests. Along with behavioural manifestations, individuals with ASD frequently report gastrointestinal disturbances. The iTARGET Autism Initiative (http://www.itargetautism.ca/) is a collaborative initiative which aims to identify children with or at risk for ASDs and provide a framework to classify patients based on genotype and deep-phenotype (clinome, metabolome, proteome, gut microbiome) profiles.

Objectives: To determine the role of the microbiome on ASD through the gut-brain axis. The central hypothesis surrounding the gut-brain axis, in regards to autism, is that ASD behaviours can be impacted by the microbiome and their metabolites which may cross the blood-brain barrier. Our analysis endeavours to identify these microbes and their metabolites.

Methods: We recruited 39 ASD affected subjects both with and without gastrointestinal symptoms. These patients will undergo WGS analysis in addition to microbiome, metabolome and proteome analysis. A control fecal sample is collected for each patient and is provided by either a sibling or same-sex parent. All collections are done through MolecularYou (https://molecularyou.com/), a Vancouver based company. 131 serum metabolites, 137 serum proteins and 73 urine metabolites have been analyzed in each affected subject. Serum and urine metabolome and proteome analysis is facilitated through MolecularYou's affiliates, The Metabolomics Innovation Centre (TMIC; https://www.metabolomicscentre.ca/) and The British Columbia Proteomics Network (BCPN; http://bcpn.ca/). The microbiome is analysed by MolecularYou affiliate, Microbiome Insights (https://microbiomeinsights.com/). The microbiome analysis consists of 16S rDNA amplicon sequencing via the Illumina MiSeq platform to determine diversity and abundance of microbial species and shotgun metagenome sequencing to identify errors in metabolism within the microbiota.

Results: Analysis of these data from 39 ASD affected subjects is currently underway. Using the same methods, we have preliminary results from five ASD affected patients, two with available control data. Our analysis has suggested that there may be an altered microbiome profile in ASD affected individuals specifically involving the Bacteroidetes and Firmicutes species. Each of the five affected patients was found to have Bacteroidetes abundance at increased levels and Firmicutes abundance at decreased levels. Three of these subjects reported gastrointestinal symptoms, while the remaining two did not. The subjects with the most altered microbiome profile also were those with the most severe behavioural manifestations of ASD.

Conclusions: Despite the small sample size, we see promising trends consistent with the literature that there is an altered microbiome profile present in individuals with ASD. These findings act as a guide for what we might expect to find following the completed analysis of our cohort. If the unique microbiome profile reaches statistical significance in association with autism and/or its symptoms, this may have implications in regards to specific diagnostic testing, management and prevention.

32 **234.032** Language-Induced Frontal Gamma Activity Is Associated with Language Ability in 18-Month-Olds with High Familial Risk of Autism

***S. Chun**[1], C. L. Wilkinson[2], H. Tager-Flusberg[3] and C. A. Nelson[4], (1)Neuroscience, Harvard University, Boston, MA, (2)Developmental Medicine, Boston Children's Hospital, Boston, MA, (3)Psychological and Brain Sciences, Boston University, Boston, MA, (4)Boston Children's Hospital, Boston, MA*

Background: In autism spectrum disorder (ASD), deficits in language development are often observed with varied severity, leading to great heterogeneity among individuals. Language ability also serves as a predictor for further sociocognitive deficits in this population. Improved understanding of early language development in children with ASD is needed for the development of effective language therapies. Prior studies suggest that infants with high familial risk of ASD show different EEG patterns related to language as compared to low risk controls. In typically developing infants and toddlers, brain oscillations in the gamma frequency (~35-50Hz) are thought to reflect cognitive and perceptual processing, including language acquisition. Our lab has previously found that increased resting frontal gamma activity is negatively associated with language ability in high familial risk toddlers, but not low risk controls.

Objectives: To investigate whether induced gamma power during a passive language-based task is associated with language ability in 18-month-olds at high familial risk for autism.

Methods: This study analyzed 18-month EEG data and language measures collected as part of the longitudinal Infant Sibling Project, comparing infants by their risk level for ASD development. Infants with a sibling with ASD were assigned to high-risk group (HRA) and those without siblings or first degree relatives with ASD were assigned to low-risk group (LRC). Language abilities were measured using the Mullen Scales of Early Learning (MSEL). Two types of auditory stimuli were presented while EEG was continuously recorded; 20 words were identified as "familiar" while the other 20 were identified as "unfamiliar" based on typical language development standards of MacArthur-Bates Communicative Development Inventories (MBCDI). Linear regression models were used to examine group differences in the relationship between language-induced frontal gamma power and receptive language ability. Maternal education was included as a covariate.

Results: Participants included 36 LRC and 44 HRA toddlers; of the high-risk toddlers, 12 later met criteria for ASD (HRA+) and 32 did not (HRA-). There was no significant difference in language-induced gamma between groups. There was a significant negative relationship between language-induced low gamma power (40-45Hz) in response to familiar words in the HRA+ group ($p=0.049$), but no relationship in LRC group ($p=0.94$), and a marginally significant positive relationship in the HRA- group ($p=0.058$) were observed. In addition, the relationship between gamma and language in HRA+ group was significantly different from HRA- group ($p<0.01$) and marginally different from LRC group ($p=0.07$) in response to familiar stimulus. No significant relationship was observed in any groups between the gamma response to unfamiliar words and language ability.

Conclusions: This study demonstrates early differences in brain-language associations between high-risk 18-months-olds with and without ASD. Future directions include investigation of the phase-locked gamma response to language stimuli. In addition, further investigation of the longitudinal trajectory of language-induced EEG power as it related to language development may further inform development of language specific therapies for ASD.

33 **234.033** Maternal Serum Biomarkers and Autistic Traits in Expectant Mothers and Their Children

A. Tsompanidis[1], *R. Holt*[2], *E. Aydin*[2], *S. Goodburn*[3], *T. Austin*[4] *and S. Baron-Cohen*[5], *(1)Department of Psychiatry, 1991, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Blood Sciences, Prenatal Screening, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, (4)University College London, London, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

The prenatal endocrine environment may be a significant factor in the development of autism, as indicated by recent findings. Several steroid hormones, including androgens, are elevated in the fetal circulation of males with autism (Baron-Cohen *et al.*, 2015). Furthermore, three separate epidemiological studies have associated autism likelihood in children with maternal polycystic ovaries syndrome (PCOS), a condition associated with high androgens (Kosidou *et al.*, 2016; Berni *et al.*, 2018; Cherskov *et al.*, 2018). In contrast, low levels of estriol in maternal serum (2nd trimester) have been shown to increase the likelihood of autism in the offspring (Windham *et al.*, 2016). Therefore, the overall ratio of androgens to estrogens may be a more suitable prenatal biomarker for the development of autism and related traits.

Objectives:

To investigate: **1**. prenatal steroidogenesis in association with autistic traits in expectant mothers and their child; and **2**. the ratio of testosterone to estradiol, as a proxy of prenatal aromatisation.

Methods:

Maternal serum samples were collected from n=126 neurotypical, pregnant women, taking part in the Cambridge Ultrasound Siblings and Parents (CUSP) study, corresponding to the first trimester of their pregnancy (weeks 10 to 14). Concentrations of the following steroids and peptides were measured: Testosterone (T), Estradiol (E2), Dehydroepiandrosterone sulphate (DHEAS), Progesterone (P), Insulin-like Growth Factor 1 (IGF1), sex hormone-binding globulin (SHBG). Samples were analysed on a DiaSorin Liaison XL automated immunoassay analyser using a one-step competitive chemiluminescence immunoassay for each hormone and two monoclonal antibodies for each peptide. The bioactive forms of testosterone and estradiol were calculated by standardising the levels according to SHBG levels. The aromatisation ratio was measured by dividing estradiol by testosterone concentrations. Expectant mothers were asked to complete the Autism Spectrum Quotient (AQ) to measure autistic traits and the Quantitative Checklist for Autism in Toddlers (Q-CHAT) online when their infant was between 18- and 20-months old. Hormone values were analysed in conjunction with autistic traits via Pearson's Correlation Coefficient. Correction of significance thresholds for multiple comparisons was performed by application of the False Discovery Rate (FDR). Latent factors driving the variance in steroid levels were calculated via the Bartlett method.

Results:

None of the analysed hormones, nor the aromatisation ratio, were significantly associated with autistic traits in the mother, in univariate analyses and following correction for multiple comparisons. However, pairwise correlations of steroid hormones revealed significant interdependence between them (e.g. estradiol to DHEAS: *Pearson's $\beta=0.629$, $p<0.0001$* & estradiol to testosterone: *Pearson's $\beta=0.466$, $p<0.0001$*). Latent factor analysis, identified three separate factors driving most of the variance in the observed steroid levels. The predicted values of the latent factor that regulated DHEAS, bioactive estradiol and bioactive testosterone were significantly correlated to maternal AQ Scores (*Pearson's $\beta=0.2515$, FDR-adjusted $q=0.026$*).

At the time of submission, Q-CHAT scores of the infants were still being collected, with their association to biomarkers to be completed and presented in May 2019.

Conclusions:

A latent steroidogenic factor affecting both androgens (DHEAS, testosterone) and estrogens (estradiol) is positively associated with autistic traits in expectant mothers.

34 **234.034** Neural Processing of Speech Sounds in Individuals with ASD and First Degree Relatives

M. Winston[1], *S. P. Patel*[2], *T. Nicol*[2], *G. E. Martin*[3], *N. Kraus*[2] *and M. Losh*[4], *(1)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (4)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Impairments in social communication are a core feature of autism spectrum disorder (ASD), and include atypical use of prosody, or the intonation, rhythm, and rate of speech (Mesibov, 1992; VanBourgonien & Woods, 1992). The midbrain's response to speech-evoked stimuli (i.e., the frequency following response; FFR) provides valuable information regarding an individual's ability to make sense of sound, including information about neural processing of speech prosody. Prior research using the FFR has documented delayed latencies of neural responses and poorer tracking of speech pitch in individuals with ASD (Russo et al., 2008; Russo et al., 2009). Importantly, atypicalities in social communication and prosody have also been reported in parents of individuals with ASD (Losh et al., 2012). Evidence of similar atypicalities in the FFR among parents of individuals with ASD could implicate the FFR as a genetically meaningful neurobiological marker of ASD related to prosody and broader social communication differences.
Objectives: To examine differences in the FFR to speech-evoked stimuli in individuals with ASD, their parents, and respective control groups.

Methods: Participants include 30 individuals with ASD, 36 controls (a subset of whom (n=29)) only completed FFR to the speech syllable /da/), 40 ASD parents, and 19 parent controls. FFRs to the speech syllable /da/ and the naturally spoken syllable /ya/ with an ascending pitch contour (i.e., resembling a question) were collected. FFRs to /da/ were analyzed for response latencies reflecting processing of the onset, offset, and acoustic properties of the syllable. FFRs to /ya/ were analyzed for fidelity of pitch tracking of the stimulus. Furthermore, parent-child correlations were conducted within the ASD and ASD parent groups to assess the familiality of FFRs to speech-evoked stimuli.

Results: Both the ASD and ASD parent groups differed from their respective control groups in response latencies. Specifically, in response to the /da/ syllable, individuals with ASD and ASD parents demonstrated delayed onset timing of processing the syllable /da/ compared to controls (*p*s < .01). Individuals with ASD also exhibited delayed processing of other acoustic features of the syllable /da/ compared to controls (*p*s<.05). Furthermore, individuals with ASD (*p* = .06; see Figure 1) and their parents (*p* = .02; see Figure 2) exhibited increased error in neural tracking of the ascending pitch contour of the syllable /ya/ compared to their respective control groups. Correlational analyses revealed that increased delays in processing the acoustic features of the syllable /da/ in ASD parents were associated with increased delays in individuals with ASD (*rs* > .42, *p*s < .10).

Conclusions: Findings revealed both delayed and diminished neural processing of speech-evoked stimuli in individuals with ASD and their parents. Such evidence of inefficient neural processing of the acoustic features of speech highlights the FFR as a potential neural marker of prosodic atypicalities characteristic of ASD. Parallel findings observed in individuals with ASD and their parents suggest that the FFR to speech-evoked stimuli may be a key neural marker of genetic liability to ASD.

35 **234.035** New Biomarker Discovery for Fragile X Syndrome: From Mouse Brains to Patient Blood

H. Bowling[1], *A. Bhattacharya*[2], *E. Berry-Kravis*[3], *K. Kirshenbaum*[4], *T. A. Neubert*[5] *and E. Klann*[1], *(1)New York University, New York, NY, (2)inSTEM Bangalore, bangalore, India, (3)Pediatrics, Neurological Sciences, & Biochemistry, Rush University Medical Center, Chicago, IL, (4)Department of Chemistry, New York University, New York, NY, (5)Dept of Cell Biology, New York University Medical Center - Skirball Institute, New York, NY*

Background: Recent clinical trials for treating the leading single gene cause of autism, fragile X syndrome (FXS), have failed in part due to a lack of biomarkers that can readily detect treatment–driven improvements and/or that can stratify the diverse FXS population. Using a novel brain-based proteomic approach, we identified proteins whose synthesis is dysregulated in FXS mice. Gene ontology analysis revealed that proteins related to metabolism, synaptic function, and intracellular signaling cascades are inappropriately synthesized in FXS mouse model brains.
Objectives: Many of the brain proteins we identified can be detected in more accessible tissues, such as blood. Therefore, we asked whether the blood levels of these proteins correlated with treatment response in FXS mice and whether any protein levels differed between FXS patients and healthy controls in plasma.

Methods: We measured the response of two proteins identified in our screen in the blood of FXS mice following three treatments shown previously to be effective in reversing phenotypes in FXS mice: PF-4708671, lithium and metformin. We then measured an expanded panel of seven proteins in human plasma, comparing 11 healthy volunteers to 11 FXS patients.

Results: In each treatment group for the FXS mice, we measured a difference in at least one marker in the drug-treated group compared to the vehicle group. Three of the seven proteins measured in human plasma showed a clear difference between healthy volunteers and FXS patients, with two additional proteins suggesting subpopulations within the FXS patient group.

Conclusions: Our data suggest that the markers identified in FXS model mouse brains are measureable in blood and may predict efficacy for drug treatment and could provide information for patient stratification for future clinical trials.

36 **234.036** Oxytocin's Role As a Biomarker of Early Social Cognitive Ability in Preschoolers with and without ASD

O. Zyga, *S. W. Russ and A. R. Dimitropoulos, Psychological Sciences, Case Western Reserve University, Cleveland, OH*

Background: Individuals with autism spectrum disorder (ASD) show pervasive deficits in social cognition (White et al., 2007). The hormone oxytocin (OT) has been implicated in the social difficulties individuals with ASD face (Carter, 2007) which has led to the use of OT as a pharmacological intervention. However, studies to date show mixed results, which has left some questioning the efficacy and importance of OT (Young, 2015). A better understanding of basal OT concentration levels and its relationship to early social cognitive abilities in both typically developing children and those with ASD could help delineate the role of OT as a potential biomarker.
Objectives: Explore the relationship between OT salivary concentration levels between preschoolers with ASD and typically developing (TD) peers

and social cognitive ability.

Methods: Nineteen children with ASD (age = 4.27; 75% male; Mullen VR = 31.12 (9.33)) and 21 TD children (age = 4.47; 61% male; Mullen VR = 47.57 (14.39)) participated in the current study. During an in-person visit, salivary samples were collected from participants at the start of the visit and used for OT extraction (Salimetrics Salivabio children's swab; Arbor Assays DetectX Enzyme Immunoassay Kit). Then, child participants completed measures of pretend play (Affect in Play Scale – Preschool version), social cognition tasks measuring joint attention, empathy, and cooperation, emotional understanding, and a parent-child interaction task.

Results: TD and ASD preschoolers did not differ in salivary OT concentration levels (F = 2.55; p = 0.16) at baseline. Across the sample, parent involvement in play correlated with child OT levels (r = 0.38, p = 0.05). Within the TD group, OT levels significantly related to interpersonal aggression in play (r = -0.47; p = 0.04), ability to recognize negative emotions (r = 0.51; p = 0.03), and joint attention ability (r = 0.59; p = 0.01). In the ASD group, interpersonal aggression (r = 0.79; p = 0.01), transformations (r = 0.79, p = 0.01) and divergent storylines (r = 0.77, p = 0.01) in pretend play correlated with baseline OT levels as did emotional recognition (r = 0.78; p = 0.07) and the ability to express empathy (r = 0.67, p = 0.05).

Conclusions: The relationship between parental involvement and OT expression suggests that more parent involvement may relate to higher child OT concentration levels irregardless of disorder category, perhaps suggesting that increasing parental involvement may then impact child OT levels. Findings also indicate that OT may have a unique relationship with specific domains of social cognitive ability, such as pretend play, emotional understanding, joint attention and empathy, in individuals with ASD as compared to TD children. This provides support for the notion of OT as a biomarker, which may have farther reaching effects that extend to individual differences in social functioning across disorder category, including the severe social impairment evidenced in ASD. These findings may allow for better understanding of how OT can be used as a biomarker for earlier identification of social cognitive deficits and potentially as a predictor of treatment outcomes.

37 **234.037** Physiological Responses to Social and Object Fear in Children with Autism Spectrum Disorder and Fragile X Syndrome

***K. D. Smith**, J. G. Smith, A. L. Hogan and J. Roberts, Department of Psychology, University of South Carolina, Columbia, SC*

Background: Children with autism spectrum disorder (ASD) and children with fragile X syndrome (FXS) are often diagnosed with comorbid anxiety. Anxiety is associated with long-term impairment; however, with early intervention, anxiety symptomology can be mitigated. Increased fear during novel social situations is associated with later social anxiety, whereas heightened fear to novel or frightening objects could be linked to specific phobia or generalized anxiety later in development. Previous research has shown that children with anxiety also have atypical physiological regulation (e.g., respiratory sinus arrhythmia, RSA), exhibiting less suppression of RSA during challenge tasks. No studies have compared physiological responses to social and object fear-inducing stimuli in children with ASD and FXS.
Objectives: The current study uses RSA to evaluate group differences between children with ASD, FXS, and typically developing (TD) controls during presses meant to evoke social fear (i.e., fear in response to a novel person) and object fear (i.e., fear in response to a novel object). Additionally, the study investigates the relationship between RSA and ASD and anxiety symptom severity.

Methods: Participants included 81 males between the ages of 3 and 6 years old: 29 ASD (chronological age *M* = 45.57, *SD* = 8.92), 26 FXS (chronological age *M* = 50.93, *SD* = 11.66), and 26 TD (chronological age *M* = 47.52, *SD* = 13.29). RSA was measured during a baseline period as well as during the Stranger Approach and Scary Spider presses of the Laboratory Temperament Assessment Battery (Lab-TAB). RSA suppression was calculated by subtracting RSA during the Stranger or Spider press from RSA during the baseline period. ASD symptom severity was assessed using the Autism Diagnostic Observation Schedule (ADOS-2). Parent-reported anxiety was determined using the Anxiety Depression and Mood Scale (ADAMS). Cognitive abilities were measured using the Early Learning Composite (ELC) of the Mullen Scales of Early Learning (MSEL).

Results: Analyses of covariance (ANCOVA, covarying for chronological age) with Bonferroni-adjusted post-hoc comparisons were used to determine group differences in RSA suppression for both tasks. For the Stranger Approach press, a main effect of group emerged, $F(2,75) = 3.51$, $p = .035$, in that TD children displayed greater RSA suppression than children with ASD, $p = .045$. The effect of group was non-significant for the Scary Spider press, $F(2,76) = 0.05$, $p = .956$. RSA suppression during the Stranger Approach press was correlated with ASD severity scores on the ADOS-2, $r = -0.31$, $p = .007$. Mullen ELC scores significantly differed between TD children and children with ASD and FXS, $F(2,73) = 83.71$, $p = .00$; however, scores did not significantly differ between the children with ASD and FXS, $p = .403$.

Conclusions: Results indicate that TD children exhibit greater RSA suppression than children with ASD during challenges involving social, but not non-social fear. However, correlations suggest that blunted RSA suppression is related to ASD symptomology rather than anxiety. Future work should explore the relationship between physiological risk markers and behavior as well as investigate other biomarkers.

38 **234.038** Probing Two Novel Proxy Markers of Excitation and Inhibition within the EEG Signal

***J. Ahmad**[1], P. Garces[2], C. L. Ellis[3], L. Mason[4], D. V. Crawley[1], J. Tillmann[5], T. Charman[6], J. K. Buitelaar[7], E. J. Jones[4], D. G. Murphy[8] and E. Loth[1], (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann-La Roche, Basel, Switzerland, (3)Social, Genetic and Developmental Psychiatry Centre, Kings College London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)King's College London, London, United Kingdom of Great Britain and Northern Ireland, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (8)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: An optimum ratio of neural excitatory and inhibitory signals is necessary for coherent brain function. It has been proposed that autism is associated with an excitation: inhibition (E:I) imbalance. We investigated two novel candidate EEG markers of excitation and inhibition. Both measures tap into 'neural noise' so we expected variance in these markers to map onto adaptive functioning and intellectual disability. Inter-trial coherence (ITC) is a measure of neural consistency; higher values mean that brain activity is more temporally aligned across trials (Makeig et al., 2004). When inhibition is reduced, the brain may not be in the optimal state to process a relevant stimulus (Levin & Nelson., 2015) leading to lower ITC. The second proxy measure, 1/f, characterizes the steepness of the power spectral density (a plot of power at each frequency) distribution. Evidence from a computational model and preclinical experiments suggests that increased inhibition leads to steeper frequency decay (Gao, Peterson & Voytek., 2017).

Objectives: To carry out case-control analysis (ASD versus TD) to determine whether, on average, both metrics differ according to diagnosis. Given both measures tap into 'neural noise' we hypothesized that these measures would vary between individuals with and without intellectual disability, and correlate with adaptive functioning.

Methods: We analysed EEG data recorded during the auditory oddball task as part of the EU-AIMS LEAP consortium (age 6-30; 1/f analysis: 262 ASD and 195 TD participants; ITC analysis: 224 ASD and 182 TD). For ITC, the reduced sample size reflects removal participants who did not show an ERP (i.e. no phase locking); however, all results maintained when these participants were included. We also created a 'level of functioning' subgroup, by comparing individuals with IQ above (high-functioning; N=386) and below (low-functioning N=71) 75.

Results: There was no overall significant difference in ITC between ASD and TD groups (t= 1.484, p =0.128), and there was no difference in ITC between high-functioning and low-functioning groups (t = -1.069, p= 0.286). For children, ITC was significantly higher in the TD child group (M= 0.196) than the ASD child group (M= 0.164), (t= 2.016, p= 0.046, d=0.399). Across all participants, higher ITC scores were associated with higher adaptive functioning scores on the VABS (r= 0.354, p= <0.001; Figure 1). For 1/f, there was no significant difference between the ASD and TD group (t=1.280, p= 0.202), but there was a significant difference between the high-functioning and low-functioning groups (t = 1.010, p= 0.002, d= 0.403). Whereby, irrespective of diagnosis, the slope was flatter for the low-functioning (M= -1.165, SD= 0.406) than the high-functioning group (M= -1.317, SD= 0.345). 1/f correlated with adaptive functioning (r=-.18, p=0.002). For both the ASD and TD groups, the histograms for both 1/f and ITC were overlapping.

Conclusions: Neither ITC or 1/f slopes differed at the case-control level between autistic and non-autistic individuals. However, ITC values were associated with adaptive functioning, and 1/f slopes were on average flatter in the group with intellectual disabilities. Thus, both markers may reflect adaptive skills, but not a clinical diagnosis of autism.

39 **234.039** Relationships between Executive Function and Activity Monitoring in Children with and without ASD: Results from the ABC-CT Interim Analysis

M. C. Aubertine[1], *F. Shic*[2,3], *S. Faja*[4], *C. Sugar*[5], *M. Sabatos-DeVito*[6], *M. Murias*[7], *G. Dawson*[8], *R. Bernier*[9], *C. Brandt*[10], *K. Chawarska*[11,12], *J. Dziura*[10], *S. Jeste*[5], *A. Naples*[11], *C. A. Nelson*[4], *S. J. Webb*[9] *and J. McPartland*[11], *(1)Seattle Children's Hospital and Research Institute, Seattle, WA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Pediatrics, University of Washington School of Medicine, Seattle, WA, (4)Boston Children's Hospital, Boston, MA, (5)University of California, Los Angeles, Los Angeles, CA, (6)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (8)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (9)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (10)Yale University, New Haven, CT, (11)Child Study Center, Yale University School of Medicine, New Haven, CT, (12)Child Study Center, Yale School of Medicine, New Haven, CT*

Background: Executive function (EF) deficits are well-documented in many children with Autism Spectrum Disorders (ASD). These EF deficits, which are critical to daily living skills such as planning and executing goals, may also contribute to the core socio-communicative deficits of ASD (Hill, 2004; Lopez et al., 2005; Faja et al., 2016). A sound understanding of the interactions between EF and social deficits, particularly at a fundamental level, may facilitate the discovery of better biomarkers and could lead to the development of more targeted therapies that address both domains. Objectives: Explore the effect of EF ability on looking percent (head, background, overall looking) during an activity monitoring paradigm in ASD and TD participants above and beyond IQ and symptom severity (ADOS calibrated severity score).

Methods: Children six to twelve years old with Autism (n = 159) and typically developing individuals (n = 64) participated. An Eyelink 1000 Plus 500 Hz was used to track participants' gaze while viewing several videos and images depicting two actresses engaged in a shared activity. Stimuli also included distractor objects placed throughout the scene and different gaze conditions (toward activity or the other actress). Trials were included if they contained valid data for more than 50% of the stimuli and if calibration error was less than 2.5 degrees. Percent time spent looking at heads (Head%), background (Background%), and the scene overall (TotalLooking%) was computed. The CASI-5 Inattentive and Hyperactive-Impulsive subscales were used as a proxy of EF.

Results: Correlations between eye-tracking outcome variables and CASI-5 EF subscales, partialling for IQ and ADOS symptom severity scores, were performed for each diagnosis group. No relationship was observed in the TD group. In contrast, Head% in ASD participants was significantly correlated with both Inattentive (r(155) = -.18, p = .024) and Hyperactive-Impulsive subscales (r(155) = -.23, p = .004), suggesting that as CASI-5 scores increased (indicating worse EF skills), time spent looking at heads decreased. A follow-up ANCOVA analysis looking at the relationship between Heads% and factorial effects of diagnosis, IQ, and CASI-5 was performed. This yielded a main effect of CASI-5 scores, F(1, 222) = 4.29, p = .039, and significant two-way interactions between CASI-5 and IQ and CASI-5 and diagnosis (F(1, 222) = 4.14, p = .043, F(1, 222) = 6.09, p = .024, respectively). The three-way interaction between diagnosis, IQ, and CASI was also significant, F(1, 222) = 5.51, p = .02.

Conclusions: Together, these analyses indicate that a complex relationship exists between CASI-5 and Head%. Although the nature of this relationship is currently unclear, the interactions suggest that CASI-5 is capturing variance in these social looking patterns that are unaccounted for by diagnosis and IQ alone. Thus, EF may play a role in social learning which may in turn impact future social skills. Interventions targeting EF domains may benefit both EF and social skills.

40 **234.040** The Electroretinogram As a Candidate Biomarker for Autism Spectrum Disorder

P. A. Constable[1], *E. R. Ritvo*[2], *A. R. Ritvo*[3], *D. A. Thompson*[4,5], *I. Lee*[6], *M. L. McNair*[3], *D. Stahl*[3], *D. Gertig*[1], *S. Quinn*[7], *J. Sowden*[8], *D. H. Skuse*[6] *and J. McPartland*[3], *(1)Flinders University, Adelaide, Australia, (2)Child psychiatry, UCLA, Los Angeles, CA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)The Tony Kriss Visual Electrophysiology Unit, Clinical and Academic Department of Ophthalmology, Great Ormond Street Hospital for Children NHS Trust,, London, United Kingdom, (5)UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, (6)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, (7)Department of Statistics, Data Science and Epidemiology, Swinburne University of Technology, Melbourne, Australia, (8)NIHR Great Ormond Street Hospital Biomedical Research Centre, UCL Great Ormond Street Institute of Child Health, University College London,, London, United Kingdom*

Background: The b-wave of the electroretinogram (ERG) depends upon glutamate synapses between the retinal photoreceptors and bipolar cells. The b-wave has been shown to be altered in two previous studies of autism spectrum disorder (ASD) and in other central nervous system disorders.

Objectives: This three-center study tested the hypothesis that the ERG discriminates individuals with ASD and typically developing (TD) individuals.

Methods: All participants with ASD met diagnostic criteria according to DSM-IV or DSM-5. In a preliminary sample as of November 2018 (data collection is ongoing), ASD (N= 52 (38M, 14F) and TD (N= 44 26M, 13F) groups were closely matched for age (ASD: 11.8 ± 0.6, range 6.0 to 19.2 years, TD 11.9 ± 0.5, range 5.9 to 19.4 years (p = .92), gender (p = .12), and iris color (p = .54). Individuals with darker irises have lower ERG amplitudes due to the absorption of light by the ocular pigmentation. A custom Troland based, nine-step, light adapted full-field ERG series was performed on both eyes using the Ret*Eval* (LKC diagnostics, Washington DC, USA). Flashes of 0.4, 0.8, 1.3, 2.5, 4.0, 6.3, 8.9, 13 and 16 cd.s.m^{-2} were presented in random order, 2/s, on a 30 cd.m^{-2} white background. The b-wave amplitudes from the eye with the largest b-wave amplitude at 16 cd.s.m^{-2} were plotted against flash strength to establish photopic hill functions for each group. Regression analysis using a Gaussian and logistic growth function to model the photopic hill derived the peak of the function for each subject using SigmaPlot 13.0 (SysStat, San Jose, USA). Repeated measures ANOVA and non-parametric tests were used to establish the flash strength that best discriminated between groups and the peak of the photopic hill with p<0.05 as significant using SPSS ver25 software.

Results: Repeated measures ANOVA revealed a significant difference between groups (F(1,85) = 5.3, p = .025) indicating a difference in the b-wave amplitude response across the flash series. Flashes of 1.3 cd.s.m^{-2} (0.1 log cd.s.m^{-2}) were the most significant (p = .002) to discriminate b-wave amplitude differences between the groups (ASD 23.0 ± 0.9 µV; TD 28.0 ± 1.2 µV). The *fitted* peaks of regression analysis for the photopic hill occurred at significantly stronger (0.08 log units; p = 0.006) flash in the ASD group (0.50 ± 0.02 log cd.s.m^{-2}) than the TD group (0.42 ± 0.02 log cd.s.m^{-2}).

Conclusions: These preliminary findings concord with previous research indicating differences in the amplitude and sensitivity of the ERG of individuals with ASD. This indicates altered retinal signaling and/or synaptic connectivity at the level of the cone and bipolar cell complex, which may reflect some of the neurodevelopmental differences in the CNS. By six months, the light adapted cone ERG peak times are adult-like, and by five years, ERG amplitudes are adult-like. Therefore, a difference in the retina's response to a pulsed increment of light holds promise as a candidate biomarker applicable in early development of children with ASD.

41 **234.041** The Role of Metal Ion Dyshomeostasis in ASD: Evaluation of Cu, Zn and Se Levels in the North American Autism Spectrum Disorder Population

*A. M. Delgado[1], M. K. Pandey[2], F. R. Howie[3], A. R. Huebner[4], J. M. Davis[1], P. L. Day[5], T. R. Degrado[2], P. J. Jannetto[5] and **S. Q. Mehta**[4], (1)Pediatrics, Mayo Clinic, Rochester, MN, (2)Radiology, Mayo Clinic, Rochester, MN, (3)Pediatric & Adolescent Medicine, Mayo Clinic, Rochester, MN, (4)Mayo Clinic, Rochester, MN, (5)Laboratory Medicine, Mayo Clinic, Rochester, MN*

Background: The importance of environmental factors and the extent of their role in the development of ASD are poorly understood. Zinc is a nutrient that may serve as a cofactor for 8 to 10% of currently identified autism risk genes. Previous studies have suggested that people on the autism spectrum have lower zinc and higher copper levels than control subjects. These studies also suggested a trend in which more severe symptoms of Autism were found in people with lower zinc levels. However, these studies were small and were performed in the Middle East or Asia. In addition, there are inconsistencies in the literature about the size of this effect depending on the source of the biosample (serum, hair, or nails).

Objectives: This study aims to determine whether the relationship between zinc/copper levels and ASD exists in a North American population and in a larger sample group size. Secondary aims of the study are to assess if there is a relationship between Zn/Cu/Se levels and language delay, functional level, and genotype. We also aim to determine if there is an optimal biosample to measure in this population based on effect size.

Methods: We are recruiting 100 children with ASD between ages 2 and 4 years and 50 age-matched control subjects from a tertiary care medical center. Control subjects passed standard pediatric screening for autism (the Ages and Stages Questionnaire), whereas all children with ASD were diagnosed using a multidisciplinary evaluation, including the ADOS-2. Zinc, copper, and selenium levels are measured in a CLIA-certified laboratory from serum, hair, and nail samples. All children diagnosed with ASD are offered clinical genetic testing (fragile X and chromosomal microarray). Once recruitment is complete, we will look for group differences between children with ASD and control subjects for zinc, copper, and selenium, as well as within ASD differences between metal ion levels and the severity of autism, language, and genetic diagnosis.

Results: Preliminary results indicated that there is a statistically significant difference between serum selenium levels, hair zinc levels, and the copper/zinc ratio between children with ASD and control subjects. There is not a high degree of concordance between metal ion levels across sample types for a given patient.

Conclusions: Our data suggest that there is a difference in metal ion homeostasis and absolute levels in young children with ASD and control subjects. We do not yet have sufficient power to determine whether there is a subtype of ASD or particular genetic diagnosis that accounts for most of this difference.

42 **234.042** The Urinary Metabolomic Profile Correlates with Clinical Severity of Young Autistic Children.

***M. Siracusano**[1,2], A. Noto[3], L. Barberini[3], C. Fattuoni[3], A. Riccioni[4], A. Benvenuto[4], V. Fanos[3], P. Curatolo[4] and L. Mazzone[4], (1)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (2)University of L'Aquila, Italy, L'Aquila, Italy, (3)University of Cagliari, Italy, Cagliari, Italy, (4)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy*

Background: The identification of sensitive and specific biomarkers of Autism Spectrum Disorder (ASD) represents one of the main challenges. In this regard, metabolomics has the potential to identify a characteristic ASD metabolic fingerprint which may support the clinician for an earlier diagnosis. New evidence shows a different urinary metabolic profile in autistic children, characterized by altered levels of gut-microbial cometabolites, tryptophan, homocitrulline, quinic, xanthurenic citric and puric acid. However, to our knowledge only few studies have correlated

the urinary metabolomics findings with clinical features and the severity of autism.

Objectives: The aim of our study was to characterize the urinary metabolic signature of ASD children compared to age matched healthy controls and to investigate the correlation between the clinical phenotype severity and the urinary metabolomic profile.

Methods: 57 children (age range 2–11 years) were enrolled in the study: 31 ASD patients and 26 typically developing children without familiarity for ASD as healthy controls. Standardized clinical assessment (Autism Diagnostic Observation Schedule, Second Edition- ADOS-2; Aberrant Behaviour Checklist - ABC) was performed for ASD children. Morning urine samples were collected for all participants and urinary metabolites were analysed and quantified by Gas chromatography–mass spectrometry (GC-MS). Correlations between the ASD metabolic fingerprint and psychological tests (ADOS-2; ABC) were investigated using the Projection to Latent Structures (PLS) method.

Results: A distinct urinary metabolomics profiles emerged in the ASD children compared to healthy controls (OPLS-DA R2 = 0.766; Q2 = 0.479 $P <$ 0.001). The purine, phenylalanine and tyrosine metabolism were the most significantly altered pathways.Different levels of gut microbial metabolites, such as hippurate, phenylalanine, tyrosine, indoleacetic, aminomalonic acids, N-acetylglucosamine and a dysregulation of metabolites expression of oxidative stress (tryptophan, cystine, uric acid) were found in ASD population. Moreover, higher levels of para-cresol and adipic acid, possible indirect results of environmental exposure, were detected in children with ASD compared to healthy controls. Finally, a positive correlation emerged between the urinary levels of para-cresol, adipic acid and the clinical severity in terms of both core symptoms (ADOS: R2=0,890273) and aberrant behaviours (ABC: R2=0,970057).

Conclusions: We report a significant difference in the urinary metabolomic profile of young idiopathic autistic children compared to healthy subjects. Our findings confirm a possible associative relationship between the autistic urinary metabolomic profile, gastrointestinal dysbiosis and oxidative stress. We also found a positive clinical correlation between core symptoms, aberrant behaviours and high concentrations of p-cresol and adipic acid whose alterations can be expression of environmental exposure. Thus, a distinct metabolomic profile related with a more severe clinical outcome emerged from our study.

43 **234.043** Urinary Markers of Oxidative Stress in Children with Autism Spectrum Disorder (ASD)

J. Osredkar[1,2], *D. Gosar*[3], *J. Maček*[4], *K. Kumer*[1], *T. Fabjan*[1], *P. Finderle*[1], *S. Šterpin*[1], *M. Zupan*[5] *and M. Jekovec Vrhovšek*[4], *(1)Institute of Clinical Chemistry and Biochemistry, University Medical Centre Ljubljana, Ljubljana, Slovenia, (2)University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia, (3)Department of Child, Adolescent and Developmental Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia, (4)University Children's Hospital, Unit of Child Psychiatry, Center for autism, University Medical Centre Ljubljana, Ljubljana, Slovenia, (5)Blood Transfusion Centre of Slovenia,, Ljubljana, Slovenia*

Background: Autism spectrum disorder (ASD) is a developmental disorder characterized by deficit in social interaction, restricted interest and repetitive behavior. Oxidative stress in response to environmental exposure plays a role in virtually every human disease and represents a significant avenue of research into the etiology ASD.

Objectives: The aim of this study was to explore the diagnostic utility of four potential biomarkers in urine.

Methods: One hundred-thirty-nine (139) patients with ASD (89% male, average age = 10.0 years, age range = 2.1 to 18.1 years) and 21 healthy children included in a control group (52% male, average age 8.2, age range = 2.5 to 13.7 years) were recruited for this study. Urinary 8-OH-dG, 8-isoprostane, dityrosine and hexanoil-lisine were determined by the ELISA method. Urinary creatinine was determined by the kinetic Jaffee reaction and all biochemical measurements were normalized in relation to creatinine. Non-parametric tests and support vector machines (SVM) with a three different kernels (linear, radial, polynomial) were employed to explore and optimize the multivariate prediction capability of these biochemical measurements for predicting an ASD diagnosis. The SVM models were computed using bootstrapping, with additional SMOTE sampling procedures (Chawla et al., 2002) utilized because of unbalanced data.

Results: Using non-parametric test we found that children with ASD had an increased concentration of 8-isoprostane compared to the control group (unadjusted p = .046). When all four biochemical measurements were combined using SVM's with a radial kernel we could predict ASD diagnosis with a balanced accuracy of 87.9% and thereby account for an estimated 31.6% of variance (p < .001). Looking at the standardized variable importance an ASD diagnosis was best explained in terms of 8-isoprostane and 8-OH-dG.

Conclusions: Our results indicate that the examined urinary biomarkers combined together may differentiate children with ASD from healthy peers to a significant extent. However, the etiological importance of these findings is difficult to assesses, due to the high-dimensional nature of SVM's and radial kernel. In addition, our results should be interpreted with care since we did not have a sufficient large enough group of both children with ASD and healthy peers to have independent training and testing samples for our SVM's. Nonetheless, our results show that machine learning methods may provide significant insight into ASD and other disorder that could be related to oxidative stress.

44 **234.044** W-Sitting and Sociomotor Behaviors in Toddlers with Autism Spectrum Disorders: True or False?

S. Goldman[1], *L. Thapa*[2], *N. M. McGowan*[2], *N. M. Yamane*[3], *D. A. Fein*[4], *L. R. Naigles*[4] *and L. D. Abbruzzese*[5], *(1)Department of Neurology, Division of Child Neurology, Columbia University Irving Medical Center, New York, NY, (2)Department of physical therapy, Columbia University Irving Medical Center, New York, NY, (3)Department of Neurology, Columbia University Irving Medical Center, New York, NY, (4)Psychological Sciences, University of Connecticut, Storrs, CT, (5)Department of Rehabilitation & Regenerative Medicine, Columbia University Irving Medical Center, New York, NJ*

Background:

Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by impairments in social interactions and communication, restricted interests, and stereotyped or repetitive behaviors. While abnormal motor features are not considered as diagnostic criteria, they are observed in more than 85% of individuals with ASD and are the earliest reliable predictor of a later ASD diagnosis among high-risk siblings of children with ASD. Movement variability is critical for social development and environmental exploration, affecting both autonomy and language development. The purposes of this study were to investigate the overall frequency and variety of gross motor behaviors in typically developing children (TD) and age-matched children with ASD during play with a parent and to focus on two distinctive motor behaviors: a) W-sitting position commonly reported as problematic and b) sociomotor dyadic Forced Transitions.

Objectives:

Using our pre-established reliable videocoding we tested three hypotheses: (1) compared to TD children, children with ASD will have reduced

frequency and variability of posture changes due to motor constraints and restricted social behaviors; (2) more children with ASD exhibit W-sitting based on reported clinical observations; and (3) more parents of ASD children will initiate Forced Transitions to facilitate reciprocity and responsiveness during play.

Methods:

Participants (TD=20; mean age=39.5 months; ASD=20; mean age=34.8) were videotaped during home-based play sessions with a parent as part of a longitudinal study to examine language development in children with ASD. Physical therapy students trained in videocoding and blind to ASD diagnoses independently rated the first five minutes of a 30-minute interaction using Datavyu software. Postures were categorized into "static" (sitting, standing, kneeling) and "dynamic" (locomotion involving moving from one location to another). Each posture (standing, sitting) was expanded into more specific positions (half-kneel, W-sitting). Codes for W-sitting (sitting posture where the bottom is on the ground and legs are splayed to opposite sides of the body; legs make a "W") and Forced Transition (child is physically moved by the parent) were developed, and inter-rater reliability for all codes ranged from 0.91 to 1.0 at a 95% confidence level. Data were analyzed in MATLAB R2017b, and descriptive statistics were calculated as Mean (SD), and Frequencies [%(n)].

Results:

Compared to age-matched TD children, children with ASD exhibited a similar frequency and variability of posture changes. As expected, Forced Transitions were significantly more frequent among the ASD dyads. However, no significant differences were found between the groups for W-sitting. In each group, 7 children exhibited W-sitting.

Conclusions:

The study emphasizes the benefit of developing interdisciplinary assessment between psychologists and physical therapists using standardized motor coding to evaluate best practices for children's motor autonomy and social exploration. Contrary to common beliefs about links between W-sitting and developmental delays, our results showed equal frequencies of W-sitting between groups. A survey of pediatric therapists revealed that W-sitting in children 12 to 96 months is common and often treated despite a lack of clear scientific evidence and access to longitudinal data. Our future longitudinal coding will inform on motor and related language trajectories.

45 **234.045** Associations between Clinical Features and Neural Markers of Sensory Processing in Children with Autism Spectrum Disorder

C. F. Layton[1,2], *E. Isenstein*[1,3], *S. Guillory*[1], *C. McLaughlin*[1], *M. Migo*[1], *I. Falade*[1], *B. Yao*[4], *H. Grosman*[1], *H. Voulgarakis*[1], *J. Zweifach*[1], *D. Halpern*[1], *P. M. Siper*[1], *A. Kolevzon*[1], *B. Roach*[5], *D. Mathalon*[6], *K. N. Thakkar*[4] *and J. Foss-Feig*[1], *(1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Northwestern University, Evanston, IL, (3)University of Rochester, Rochester, NY, (4)Michigain State University, Department of Psychology, East Lansing, MI, (5)Northern California Institute for Research and Education, San Francisco VA Medical Center, San Francisco, CA, (6)University of California, San Francisco, San Francisco, CA*

Background: Sensory and motor deficits are key features of the autism spectrum disorder (ASD) phenotype. Recently, we proposed that deficits in *corollary discharge (CD),* neural signals that allow actions to modulate perception, could underlie many core ASD symptoms. CD signals are copies of movement signals, which are sent to the sensory areas of the brain at the same time that the motor commands themselves are sent to lower motor regions. They allow organisms to suppress sensory consequences of self-generated action and attune more to external input. Decreased CD signaling in ASD could contribute to both hypo-responsiveness to external sensory stimuli and internal preoccupation seen in the ASD phenotype. Objectives: To test whether (i) suppression of the neural response to self-generated tones (engaging CD) versus externally-generated tones (no CD) is reduced in children with ASD, and (ii) whether these CD alterations are associated with clinical symptoms in these children.

Methods: This study used an EEG paradigm to compare neural signatures of CD between typically developing (TD) children (n=10) and children with ASD (n=15), and to relate putative CD alterations with sensory hypo-responsiveness and overall symptom severity.CD was indexed by suppression of the N1 event-related potential (ERP) between two conditions: Self-generated tones, where participants initiated a tone by pressing a button on a response pad (CD condition), and externally-generated tones, where participants passively listened to tones played back by the computer (no CD condition). Mean N1 amplitudes were extracted from central electrodes, separately for each condition**.** Correlations between N1 suppression and clinical scores on the Social Experience Questionnaire (hypo-responsiveness and sensory-seeking subscales) and Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2) total score were calculated.

Results: Typically developing participants exhibited significant suppression of N1 amplitude between externally- and self-generated conditions ($t(10)= 4.87$, $p= 0.001$). No significant N1 suppression was observed in ASD ($t(15)= 1.70$, $p= 0.11$). Participants with ASD showed attenuated suppression to self- versus externally-generated tones (1.17 μV) compared to the TD group (2.57 μV), suggesting a deficit in CD signaling ($d = 0.63$). The ASD group scored significantly higher in sensory hypo-responsiveness ($t(23)= 3.96$, $p< 0.001$) and sensory-seeking behaviors ($t(23)= 2.19$, $p= 0.04$) than the TD group. Lesser N1 suppression was associated with greater hypo-responsiveness on the SEQ across both groups ($r = -0.41$, $p= 0.04$). Though non-significant, the correlation between N1 suppression and sensory-seeking behaviors on the SEQ was of medium size across both groups ($r= -0.34$, $p= 0.09$). Lesser N1 suppression was also associated with higher ADOS-2 total scores ($r= -0.55$, $p= 0.03$).

Conclusions: These results suggest that CD signaling during self-generated action is attenuated in ASD and relates clinically to both sensory experiences and core symptom levels. If correlations between EEG measures and clinical symptoms are maintained in a larger sample, this study could lead to a breakthrough in our understanding of the neural basis of several core symptoms of ASD, in turn leading to novel, targeted treatment approaches that could be applied in the context of very early intervention.

46 **234.046** CK-BB: A Novel Biomarker in Autism Spectrum Disorders

S. Bruce, ***K. Harum****, M. Mongo and A. Walton, Clinic for Special Children, Wilmington, NC*

Background:

Creatine kinase (CK) is an enzyme that aids in the transfer of phosphate groups from ATP to creatine phosphate to meet metabolic energy demands of tissues such as brain and muscle (Sharma, Rosenberg, Bennett, Laskowitz, Acheson, 2016). Creatine kinase B type (CK-BB) is an isozyme of CK primarily found in the brain. Detection of CK-BB in serum suggests a permeable blood brain barrier and neuronal injury (Sahu, Nag,

Swain, Samaddar, 2017). The potential use of CK-BB as a biomarker for Autism Spectrum Disorders (ASD) has not yet been explored.

Objectives:

The current study sought to identify endophenotypes in autism by observing variations in a marker of neuronal injury in children diagnosed with ASD; specifically, CK-BB.

Methods:

A community population of children with neurodevelopmental disorders, meeting DSM-V criteria for autism underwent consultation for diagnostics and treatment. These children were evaluated for elevations in CK and its isozymes, including the BB fraction (CK-BB), along with a standard array of diagnostic assessments for children with autism. Patients were pulled from a community clinical population (n=435). Their laboratory data and clinical categories were tabulated in a spreadsheet in accordance with the guidelines and upon the approval of the regional IRB (SEAHEC, Study number 1711-1). Standard statistical analyses were applied. CK-BB was analyzed by Labcorp® according to their agarose gel electrophoresis with densitometry method.

Results:

There were no significant elevations in CK total in this population, yet there is significant elevation of CK-BB, a protein strongly correlated with brain injury and blood brain barrier permeability. These data suggest that a community population of children with autism have elevated CK-BB in serum regardless of their regression status and these levels are significantly higher when compared to normally developing children (Figure 1) ($p<0.001$).

Furthermore, children with regression had higher levels of total CK-BB fraction compared to children without regression (Figure 2) ($p=0.01$). In general, children over 5 years with autism tend to express lower levels of CK-BB when compared to younger children under age 5 with autism.

Conclusions:

Identifying autism with biological markers will aid in the understanding of autism's diverse etiology, and lead to more rapid biological and medical treatments. We believe that CK-BB can be used as an inexpensive and readily attainable biomarker for the detection of brain injury and/or blood brain permeability in an autistic population.

47 **234.047** Atypical Cortical Processing of Pitch Contours Predicts Social Communication Deficit in Tonal-Language-Speaking Children with Autism

L. Yu[1], *S. Wang*[1], *X. Wu*[2], *D. Huang*[2], *L. Wei*[2] *and Y. Zhang*[3], *(1)Psychology, South China Normal University, Guangzhou, China, (2)Guangzhou Rehabilitation & Research Center for Children with ASD (Guangzhou Cana School), Guangzhou, China, (3)Department of Speech-Language-Hearing Sciences, University of Minnesota, MINNEAPOLIS, MN*

Background: Linguistic relevance shapes the neural coding of critical acoustic features pertinent to one's native phonology. Pitch contour is a defining feature of lexical tones in tonal languages such as Mandarin Chinese, and native Chinese listeners' cortical responses have been found to be more sensitive to tones with a curvilinear frequency trajectory than native English listeners (Krishnan, Gandour, & Suresh, 2014). It remains unknown to what extent whether such a language-specific neural marker of pitch encoding is developed in tonal language users with autism. Objectives: The current electrophysiological study employed nonspeech stimuli similar to those in Krishnan et al. (2014) varying in pitch trajectory to examine closely the cortical processing of linguistically relevant pitch information in Chinese children with autism. Clinical significance was explored by examining the correlations between the neural measures and autism core symptoms.

Methods: EEG was recorded from 22 native Chinese-speaking children with autism (9~13 years) and 27 age-matched TD controls. The participants were instructed to watch a self-chosen muted cartoon while ignoring any sounds. The stimuli were trains of nonspeech sounds containing either a prototypical Chinese rising tone (Tone 2 or T2) with a naturalistic curvilinear frequency trajectory or a linearly accelerated T2 that is linguistically unnatural. The linear T2 shared the same onset and offset frequencies of the prototypical T2, thus coarsely approximated the frequency trajectory of T2. The purpose of using nonspeech was to eliminate the influence from phonological and semantic contexts and thereby examine more precisely the acoustically driven cortical encoding of the pitch features. The ERP (event-related potential) responses in selected time windows were examined to see possible between-group differences. Scores from Social Communication Questionnaire (SCQ; Rutter, Bailey, & Lord, 2003) were obtained from the autism group to see if language-dependent auditory encoding could autism symptom measure.

Results: Both groups demonstrated significantly larger N250 amplitude in the processing of the prototypical curvilinear T2 relative to the linear T2. However, a group*stimulus condition interaction was observed in an earlier window of 180-230 ms. Specifically, the prototypical contour of T2 but not the linear contour produced ERP positivity in the TD group. In contrast, the ERPs for the two tones in the autism group did not differ, indicating a lack of distinction. Moreover, there was a significant correlation between ERP in this window at Pz for the linear T2 and SCQ measure. Greater ERP positivity for the linear T2 (towards reduced prototypical vs. linear distinction) was predictive of more severe autism symptoms.

Conclusions: Chinese school-age children with autism and TD controls were both sensitive to the linguistic pitch features represented by the prototypical and linear Tone 2 trajectories in later cortical processing stage. However, unlike the TD group, the autism group failed to show an early ERP distinction of the tones. The correlation between SCQ and language-dependent cortical pitch encoding suggests a potential link between low-level auditory perception and the clinical symptomology of autism. The results call for further developmental studies of atypical language-dependent perceptual reorganization and underlying mechanisms in autism.

Poster Session

Relations between Production of Third-Person Pronouns and Mental State Terms in the Narratives of Children with ASD

ABSTRACT WITHDRAWN

Background:
Studies of the narrative abilities of children with autism spectrum disorder (ASD) have thus far yielded mixed results: on the one hand studies have found that children with ASD produce shorter narratives and utterances [1–3], fewer mental state terms [2,4–6], and more ambiguous pronouns [6–9] than language-matched neurotypical (NT) children. Other studies, by contrast, have found no difference in narrative length/MLU [5,9] or the use of mental state terms [10]. Furthermore it is unclear whether there is a relationship between the ability to use these different aspects of narrative language.

Objectives:

We sought to examine the relationship between production of third-person pronouns with either clear or ambiguous referents and the production of mental state terms in the narratives of children with ASD. We hypothesized that children who produced more mental state terms would also produce more 3rd-person pronouns with clear referents, since these require active monitoring of interlocutors' mental states.

Methods:
